Comments to the Author

Line 221 Intestinal ceca bifurcation in preacetabular region, forming caecal shoulders before running Is it the caeca that bifurcate? 'Intestinal bifurcation' is a more usual descriptor.

- **Changed**

Perhaps 'preacetabular' might confuse some readers as there is no mention of an acetabulum (It is referred to as a ventral sucker in the description and acetabulum in parts of the discussion). It could be replaced by 'in forebody'.

- **Although we don't think readers of *Parasitology* will be confused by the term 'acetabulum', we changed it as the reviewer requests / to 'anterior to the ventral sucker'.**

The American spelling 'ceca' and the British spelling 'caecal' are used in the same phrase. Use just one spelling consistently.

- **Changed**

Line 223. sucker, muscular, trilobed structure well visible – easily visible

- **Changed**

Line 284. The posterior testis in most descriptions is moon-shaped. The moon is a sphere! Use a more precise descriptor.

- **We changed this to 'crescent shaped', the term we use in morphological description**

SUMMARY

The genus *Clinostomoides* Dollfus, 1950 was erected to accommodate a single worm from *Ardea goliath* sampled in the Belgian Congo. The specimen was distinguished from other clinostomids by its large size and posterior genitalia. In the following years, metacercariae of *Clinostomoides brienii*, have been described in *Clarias* spp. in southern and western Africa. A few authors have referred to *Clinostomum brienii*, but all such usages appear to be *lapsus calami*, and the validity of *Clinostomoides* remains widely accepted. In this study our aim was: position *Clinostomoides brienii* among the growing clinostomids molecular database, and redescribe the species with emphasis on characters that have emerged as important in recent work. We sequenced two nuclear (partial 18S and ITS) and one mitochondrial marker (partial cytochrome *c* oxidase I) and studied morphology in metacercariae from hosts and localities likely to harbor the type species (*Clarias* spp., Democratic Republic of the Congo, South Africa). Phylogenetic analysis shows *Clinostomoides brienii* belongs within *Clinostomum* Leidy, 1856. We therefore transfer *Clinostomoides brienii* to *Clinostomum*, amend the diagnosis for the genus *Clinostomum*, and provide a critical analysis of other species in *Clinostomoides*, all of which we consider *species inquirendae*, as they rest on comparisons of different developmental stages.

Key words: Yellow grub, halzoun, molecular prospecting, hybridization, incomplete lineage sorting, DNA barcode, heron, catfish

KEY FINDINGS

- Genus *Clinostomoides* Dollfus, 1950 originally distinguished from other clinostomids by large size and posterior genitalia.

- Morphological and molecular study of metacercariae from hosts and localities likely to harbor the type species *Clinostomoides brienii* (*Clarias* spp., southern Africa).

- Phylogenetic analysis of three markers (18S, ITS rDNA and CO1 mtDNA) shows *Clinostomoides brienii* belongs within *Clinostomum* Leidy, 1856.

- Amended diagnosis for *Clinostomum* to accommodate inclusion of *C. brienii*.

- Critical analysis of other species in *Clinostomoides*, all considered species inquirendae.

INTRODUCTION

The genus *Clinostomoides* was erected by Dollfus (1950) to accommodate a single adult collected from the esophagus of *Ardea goliath* sampled in the Belgian Congo (now Democratic Republic of the Congo – DRC). The type species, *C. brienii* Dollfus, 1950, was distinguished from *Clinostomum* based on its large body size (30 mm), the genital complex in the posterior (rather than middle or across middle and posterior) third of body, and the genital pore located ventral to the posterior testis (rather than lateral to the anterior testis). In the following years, metacercariae of *C. brienii* were described by Prudhoe (1957) from *Clarias lazera* collected in Belgian Congo, by Manter and Pritchard (1969) from *Clarias* sp. from Rwanda, by Fischthal and Thomas (1970) from *C. senegalensis* in Ghana, by Barson *et al.* (2008) and by Jansen van Rensburg *et al.* (2013) from *C. gariepinus* sampled in Zimbabwe and Botswana, respectively. Outside the African continent, Mirzoeva (1981) described one adult of *C. brienii* collected from the esophagus of *Ardea purpurea* in Azerbaijan, and metacercariae of *C. brienii* were also reported in the Philippines (Arthur and Lumanlan-Mayo, 1997).

73 Additional species of *Clinostomoides* have been described in Central India, the first being *C.*
74 *dollfusi* Agarwal 1958, followed by *C. ophicephali* (Tubangui and Masiluñgan, 1935)
75 Agarwal 1958 (transferred from genus *Clinostomum*), *C. chauhani* Pandey 1971, *C. rai* Rai
76 1970, *C. meerutensis* Pandey and Tyagi 1986, *C. pandeyii* Singh and Sharma 1994, and *C.*
77 *baughi* Pandey 1998. However, all were erected based either on comparisons among these
78 regional species or with the earliest species in the region, *C. dollfusi*. Most importantly, all,
79 including *C. dollfusi*, were based on metacercariae. This is problematic because in erecting *C.*
80 *dollfusi*, Agarwal (1958) compared metacercariae with the adult described by Dollfus (1950),
81 not with metacercariae described by Prudhoe (1957). Manter and Pritchard (1969)
82 synonymized *C. dollfusi* with *C. brieni*, and their doubts about the morphological characters
83 used to erect the junior species were confirmed by Fischthal and Thomas (1970). However,
84 subsequent work in India has not taken the latter studies into account and continues to treat as
85 valid *C. dollfusi* and other species erected in comparison to it (e.g. Pandey and Agrawal,
86 2013). Finally, the species described by Dollfus has occasionally been reported as
87 *Clinostomum brieni*, in *lapsus calami*. Prudhoe (1957) and Douellou (1992) used both
88 “*Clinostomum brieni*” and “*Clinostomoides brieni*” as names for the same species, and Lio-Po
89 *et al* (1983) listed “*Clinostomum brieni*,” but without taxonomic comment or support. Other
90 than these isolated cases, the genus *Clinostomoides* and its type species *Clinostomoides brieni*
91 are widely considered valid (e.g., Kanev *et al.* 2002).

92 A combination of molecular and morphological approaches is a useful way to resolve
93 situations like this, as has already been shown in other clinostomids, i.e., *Clinostomum* Leidy,
94 1856 (Caffara *et al.* 2011; Sereno-Urbe *et al.* 2013), *Euclinostomum* Travassos, 1928
95 (Senapin *et al.* 2014; Caffara *et al.* 2016), *Odhneriotrema* Travassos, 1928 (Woodyard *et al.*
96 2017) and *Ithyoclinostomum* Witenberg, 1925 (Briosio-Aguilar *et al.* 2018). However, few
97 DNA sequences from *Clinostomoides* are currently available for comparison. Athokpam *et al*

(2014) provided rDNA sequences from *C. brienii*, but without supporting morphological information. Moreover, the identification of *C. brienii* by these authors was questioned by Briosio-Aguilar *et al* (2018) because of the close relationship of its 28S sequence to data from *Clinostomum*. It is also relevant that the material sequenced by Athokpam *et al* (2014) was from *Heteropneustes* in Northeastern India, rather than the region or hosts (central and southern Africa, *Clarias*, *Ardea*) where the genus originated and is better known. The aim of this work was to provide a redescription of *Clinostomoides brienii* metacercariae based on morphological and molecular analyses, following Matthews and Cribb (1998), and to provide an updated critical analysis of previously described species. To this end, we collected in localities and hosts in which we were likely to encounter the same species as Dollfus (1950) and Prudhoe (1957), with the aim of characterizing the type species. Our results led us to transfer *Clinostomoides brienii* to *Clinostomum* and to consider species of *Clinostomoides* from India as *species inquirendae*.

MATERIALS AND METHODS

Two metacercariae of *Clinostomoides* sp. were collected from *Clarias gariepinus* sampled at Phalaborwa barrage, Limpopo province (South Africa) and four from *C. ngamensis* sampled in the Democratic Republic of the Congo (1 from Lake Tshangalele, Kapolowe Mission and 3 from Kiswishi River near Futuka Farm). All were recovered from the body cavity, cleaned in saline and preserved in 70% ethanol.

Total lengths of metacercariae were measured before cutting a small piece of the posterior end for molecular analyses. Morphometrics of hologenophores (*sensu* Pleijel *et al.* 2008) were taken after clarification with Amman's lactophenol and staining by Malzacher's method (Pritchard and Kruse, 1982). Line drawings were made with the aid of a drawing tube, and measurements are given in micrometers following Matthews and Cribb (1998). DNA was

123 extracted from hologenophore subsamples using a PureLink Genomic DNA Kit (Invitrogen)
 124 following the manufacturer's protocol. Amplification of 18S and Internal transcribed Spacer
 125 1—5.8S—Internal Transcribed Spacer 2 (ITS) rDNA employed protocols and primers of
 126 Gustinelli *et al.* (2010), cytochrome *c* oxidase I (CO1) mtDNA those of Moszczyńska *et al.*
 127 (2009).
 128 Amplified products were resolved on a 1% agarose gel stained with SYBR Safe DNA Gel
 129 Stain in 0.5× TBE (Molecular Probes – Life Technologies). For sequencing of 18S, ITS and
 130 CO1, bands were excised and purified by NucleoSpin Gel and PCR Cleanup (Mackerey-
 131 Nagel) and sequenced with an ABI 3730 DNA analyser at StarSEQ GmbH (Mainz,
 132 Germany). Contigs were assembled with Vector NTI Advance™ 11 software (Invitrogen)
 133 and sequences are published in GenBank under the following accession numbers:
 134 MH606186-90 (18S), MH238412-16 (ITS) and MH253044-48 (CO1).
 135 Pairwise p-distances and models of nucleotide evolution (BIC) were calculated using MEGA
 136 6.06 (Tamura *et al.* 2013). For trees constructed with Bayesian Inference, in MrBayes 3.2.6
 137 (Ronquist *et al.* 2012), nst=2+G was used for ITS and 18S, and GTR+G+I was used for CO1.
 138 The K2P+G-model was used for Maximum Likelihood analysis in MEGA of 18S and ITS
 139 rDNA while GTR+G+I was used for ML analysis of CO1 mtDNA.
 140 The newly generated sequences of 18S, ITS and CO1 were aligned along with one or two
 141 representative sequences of *Clinostomum* species (*C. complanatum*, *C. cutaneum*, *C.*
 142 *phalacrocoracis*, *C. tilapiae*, *C. philippinensis*, *C. marginatum*, *C. tataxumui*, *C. album*, *C.*
 143 *poteae*, *C. heluans*, *C. attenuatum*, *C. detruncatum*, *C. arquus*, *C. caffarae*, *C. cichlidorum*)
 144 plus undescribed or unidentified species of *Clinostomum* (Locke *et al.* 2015; Caffara *et al.*
 145 2017). *Euclinostomum heterostomum* (ITS: KP721422, CO1: KP721404), *Odhneriotrema*
 146 *incommodum* (ITS: MF766000, CO1: MF766003) and *Ithyoclinostomum* (ITS: MH159753,
 147 CO1: MH159752) were used as outgroup for the subfamily Clinostomatinae, while

Tylodelphys immer (18S and ITS: MH521252; CO1: MH536513), *Cyathocotyle prussica* (18S and ITS: MH521249; CO1: MH536510), *Schistosoma mansoni* (18S: U65657; ITS: AY446082) as outgroup for Clinostomidae. All codon positions in the CO1 alignment were used in the analysis because of lack of evidence of nucleotide saturation (Iss =0.237, Iss.c=0.697, df=472, P=0, Xia *et al.* 2003; Xia and Lemey, 2009).

RESULTS

Among five 18S rDNA sequences 1826-1877 bp in length obtained from African samples of *C. brienii* in the present study, there were four variable sites, all transitions, i.e. mean divergence 0.1%, range 0-0.2%. All variation was in two sequences from South Africa; three 18S sequences from Congo were identical. An 18S sequence (KF781300, 1907 bp) of Athokpam *et al.* (2014) from *C. brienii* from *Heteropneustes fossilis* in Manipur differed at 32 positions (1.7%) from another 18S sequence by the same authors (KF811009, 1859 bp) from the same host in Meghalaya (the latter sequence is not mentioned in the paper of Athokpam *et al.* 2014). Variation in 18S between the five African *C. brienii* sequences and the two Indian isolates averaged 1.4% (range 0.5-2.6%). Phylogenetic analysis showed that 18S sequences from Indian and African *C. brienii* form a well-supported clade nested within *Clinostomum* species. The *Clinostomum* + *C. brienii* clade is also well supported, and comparatively deeply divergent from *Euclinostomum*. Variation among 18S sequences of *Clinostomum* spp. averaged 0.9% (range 0.2-1.5%) and in the *Clinostomum* + *C. brienii* clade, 18S variation averaged 1.1% (range 0-3.6%). All the highest divergence values ($\geq 1.8\%$) in the latter clade were associated with the unpublished *C. brienii* sequence KF811009. Variation between *Euclinostomum* and members of the *Clinostomum* + *C. brienii* clade averaged 2.8% (range 2.4-5.0%).

172 The five ITS rDNA sequences 1005-1028 bp in length from African *C. brien*i were identical
 173 to each other and to the 300-bp ITS2 sequence of *C. brien*i (KF781298) of Athokpam *et al.*
 174 (2014). The ITS of *C. brien*i varied by a mean of 5.7% (range 4.7-7.1%) from species of
 175 *Clinostomum*. Variation in ITS among species of *Clinostomum s.s.* was of similar magnitude:
 176 mean 4.9% (range 0.1-8.6%). In contrast, ITS variation among members of the genera
 177 *Euclinostomum*, *Odhneriotrema*, and *Clinostomum* + *Clinostomoides* averaged 15.2% (range
 178 13.9-16.3%).

179 The CO1 sequences of four specimens of *C. brien*i were identical but that of one specimen
 180 (MH253045, from *C. gariepinus* in South Africa) differed by 11% from the other four. This
 181 specimen did not differ morphologically from the other five *C. brien*i examined, and its 18S
 182 (MH606187) and ITS (MH238413) sequences were not similarly divergent (Figs 1, 2). The
 183 CO1 of this specimen differed by 0.2% from *Clinostomum* morphotype 3 (KY865667, from
 184 the *Amphilius uranoscopus* in South Africa). The DNA from this specimen was amplified and
 185 sequenced an additional four times with the same results. The BI and ML trees were based on
 186 a 473 bp CO1 alignment and had little statistical support at deeper nodes, but both showed *C.*
 187 *brien*i within *Clinostomum*. The *C. brien*i specimen MH253045 grouped with *Clinostomum*
 188 sp. morphotype 3, while the other four *C. brien*i sequences form a monophyletic clade within
 189 the Old-World clade of *Clinostomum* species. The four monophyletic *C. brien*i sequences
 190 differ by mean 15.3% (range 13-19.5%) from other *Clinostomum* species. Interspecific CO1
 191 variation in *Clinostomum* is similar, with mean 16.3% (range 3.5-22.1%). The mean
 192 intergeneric CO1 distances between members of *Odhneriotrema*, *Clinostomoides* +
 193 *Clinostomum*, *Euclinostomum* and *Ithyoclinostomum* is 19.8% (range 17.3-23.5%).

194 Analyses of three molecular markers indicate *Clinostomoides* should be regarded as junior
 195 synonym of *Clinostomum*, as amended below. Tree topologies (Figs. 1-3) show relatively
 196 deep divergence between *Odhneriotrema*, *Euclinostomum* and *Clinostomum* whereas

197 *Clinostomoides* falls within a clade of *Clinostomum* species. Genetic distances between *C.*
198 *brieni* and *Clinostomum* species are comparable to those within *Clinostomum* s.s. and inferior
199 to distances among other clinostomid genera.

200

201 *Clinostomum* Leidy, 1856

202 (Synonym *Clinostomoides* Dollfus, 1950)

203 Family Clinostomidae Lühe, 1901

204 Subfamily Clinostominae Lühe, 1901

205 Body medium to very large, linguiform, stout, convex dorsally and concave ventrally.

206 Tegument smooth or with spines. Oral sucker may or may not be surrounded by collar-like
207 fold when retracted. Ventral sucker muscular, well developed, always larger than oral sucker.

208 Caeca long, simple, with more or less sinuous wall, particularly in anterior half of body, but
209 lacking lateral branches or diverticula. Testes smooth or irregular in shape, in posterior half of
210 body. Ovary intertesticular, to right of medial line. Vitelline follicles in lateral fields

211 anteriorly, from level of intestinal bifurcation or ventral sucker to posterior extremity, may
212 remain lateral and extracaecal or become confluent posterior to genital complex. Uterus

213 intercaecal, extending from Mehlis' gland to fill part of total distance to ventral sucker.

214 Genital pore anterior, lateral or posterior to testicular-ovary complex. Cosmopolitan. Type
215 species *Clinostomum complanatum* (Rudolphi, 1819).

216 *Morphological Description of Clinostomum brieni* (Dollfus, 1950) n. comb. (Fig. 4, Table 1)

217 (based on 5 hologenophores and 1 paragenophore)

218 (Synonym *Clinostomoides brieni* Dollfus, 1950)

219 Body regularly elongated, narrow, tongue-shaped. Oral sucker small, with indistinct marginal
220 limits. Pre-pharynx cup-shaped elongated, thick, muscular. Pharynx visible, muscular.

Intestinal bifurcation anterior to ventral sucker, forming caecal shoulders before running laterally to ventral sucker to posterior end of body. Ventral sucker robust, larger than oral sucker, muscular, trilobed structure easily visible. Caeca provided with small lateral pockets becoming more digitated posteriorly to ventral sucker. Whole genital complex in posterior part of posterior third of body. Testes two, tandem, intercaecal, transversely elongated. Anterior testis bow-tie shaped. Posterior testis Y- to crescent shaped with anterior margin concave. Cirrus sac comma-shaped, thick walled, intertesticular dextral, from right posterior margin of anterior testis to anterior margin of posterior testis, genital pore opening in concave margin of posterior testis. Ovary small, intertesticular dextrally to cirrus sac, close to right margin of posterior testis. Uteroduct emerging from ootype complex runs around left margin of anterior testis, ascending sinistrally with some undulation to slightly above metraterm before looping posteriorly on itself entering directly into the proximal part of uteroduct and opening into uterine sac. Uterine sac median elongate narrow, tip reaching the posterior part of middle third of body. Tegument armed with spines (8-11 μm) from posterior part of oral sucker to posterior end of body. Excretory bladder Y-shaped, postcaecal, arms extending anteriorly in extracaecal position. Excretory pore terminal.

238

239 DISCUSSION

Our original aim was redescribe metacercariae of *Clinostomoides brieni* and assess the relationship of the species with other clinostomids using DNA. Unexpectedly, the molecular data strongly indicate the species belongs within *Clinostomum*, which led us to amend the diagnosis of the genus to accommodate *Clinostomum brieni* n. comb. The genus *Clinostomoides* was limited to Afrotropic and Indo-Malayan regions, and most reports are from *Clarias* or *Heteropneustes*, which are closely related siluriform genera occurring in the

same regions (Hardman, 2005; Kushwaha *et al.* 2015; Froese and Pauly, 2018). The phylogenetic association of *C. brienii* with a clade of Old-World *Clinostomum* species (Figs 1-3) is consistent with a biogeographic pattern that continues to be observed as data accumulate from more species of *Clinostomum* (Locke *et al.* 2015; Pérez-Ponce de León *et al.* 2016; Rosser *et al.* 2018), which adds further evidence that *C. brienii* belongs to *Clinostomum*.

One specimen we collected was morphologically indistinguishable and shared identical rDNA sequences with other *C. brienii*, but its CO1 (MH253045) was highly divergent, and nearly identical to *Clinostomum* morphotype 3, which Caffara *et al.* (2017) obtained from mochokid and amphiliid catfishes in South Africa. We believe this can be most plausibly explained by hybridization. Both *C. brienii* and *Clinostomum* morphotype 3 infect siluriform second intermediate hosts in the same region, which are preyed upon by local ardeid definitive hosts, including the type host of *C. brienii*, *A. goliath* (Mock and Mock, 1980). Other than this particular specimen, *C. brienii* and *Clinostomum* morphotype 3 appear to be distantly related (Figs. 1, 2). This argues against another possible explanation for mitochondrial haplotype sharing between *C. brienii* and *Clinostomum* morphotype 3, incomplete sorting among recently separated species. In any event, when viewed together with the highly distinctive morphology of *C. brienii*, both hybridization and incomplete lineage sorting suggest species belonging to a single genus, which supports our main taxonomic conclusion.

The most distinctive characters of *Clinostomoides* were the size of the adult (30 mm) described in *A. goliath* by Dollfus (1950), the extremely posterior position of the genital complex, and the position of the cirrus sac and genital pore within the genital complex, characters considered also in regional descriptions of metacercariae (Prudhoe, 1957; Manter and Pritchard, 1969; Fischthal and Thomas, 1970; van Rensburg *et al.* 2013). The most obvious distinction of *Clinostomoides*, its large size, is noteworthy in that the adult is known only from the largest of ardeids, *A. goliath* (Mock and Mock, 1980). In light of the molecular

evidence that *Clinostomoides* belongs within *Clinostomum*, the other characters may be considered as size-related allometric changes.

The clinostomid metacercariae we collected from *Clarias* species in South Africa and Democratic Republic of the Congo were morphologically consistent with previous descriptions of *C. brienii* in the same host and region (Prudhoe, 1957; Manter and Pritchard, 1969; Fischthal and Thomas, 1970; van Rensburg *et al.* 2013). The only inconsistency was the pharyngeal morphology. Fischthal and Thomas (1970) reported a thick-walled, muscular pre-pharynx and very muscular pharynx (as observed in our specimens), while Prudhoe (1957) reported the pharynx absent, Manter and Pritchard (1969) did not mention it, and van Rensburg *et al.* (2013) reported a short pre-pharynx and muscular pharynx. In our opinion, these structures are probably always present but not always visible.

As the genital complex provides reliable features for discriminating species of *Clinostomum* (i.e. Caffara *et al.* 2017, Sereno-Urbe *et al.* 2018, see Table 2), it can also shed light on prior records of *Clinostomum brienii*. The posterior testis in most descriptions is crescent-shaped, and showed this form in two of six subjects we examined, but in four worms the posterior testis was Y-shaped, as also reported by Fischthal and Thomas (1970). In metacercariae of *Clinostomum*, testes are more digitated than in pre-adults/adults (Ukoli, 1966). The only description of the adult of *C. brienii* is that of Dollfus (1950), who reported testes similar to those later described in metacercariae, except for small marginal lobules in the adult organs. Thus, in this species of *Clinostomum*, developmental variation in the morphology of the testicular margin appears to be reversed (going from smooth to more digitated), although data are needed from additional adults to confirm this. The cirrus pouch (CP) in *C. brienii* is well developed and lies between the testes, at a variable distance from the posterior border of the anterior testis and touching the concave part of the posterior testis where the genital pore opens. This pattern has been observed in all previous descriptions of *C. brienii* except that of

Fischthal and Thomas (1970), in which the CP did not touch the posterior testis. Finally, in all metacercarial descriptions the uteroduct forms a similar loop devoid of eggs, which becomes filled with eggs in the adult (Dollfus, 1950).

Molecular data indicate a single species (albeit with potential capacity to hybridize) of *Clinostomum brienii* among samples spanning approximately 1500 km of the known geographic range of this species, including the type region. Morphological differences among our specimens and those of prior regional accounts (Dollfus, 1950; Prudhoe, 1957; Manter and Pritchard, 1969; Jansen van Rensburg *et al.* 2013) therefore likely represent intraspecific variation. This can provide a useful perspective for considering species of *Clinostomoides* described from the Indian subcontinent, the first of which was *C. dollfusi*, which Agarwal (1958) described from metacercariae from *Clarias* sp. and *Heteropneustes* (= *Saccobranthus*) sp. collected in Jabalpur. Agarwal (1958) emphasized body length (7.8-9.8 mm in the Indian metacercariae vs the 30 mm in adult holotype of *C. brienii*), the absence of lateral sacculations of the uterus, and distance between suckers. However, all these characters are in fact typical of metacercariae of *C. brienii* (Manter and Pritchard, 1969; Fischthal and Thomas, 1970; Van Rensburg *et al.* 2013; present study), if not of the larger adult holotype. All other species of *Clinostomoides* in this region are from *Heteropneustes*. *Clinostomoides chauhani* Pandey, 1971, was described from the body cavity and viscera of *H. fossilis* collected in Lucknow, based on comparison with *C. dollfusi* and *C. ophicephali*, which were both synonymized with *C. brienii* by Manter and Pritchard (1969) and Fischthal and Thomas (1970). The species *C. chauhani* is said to possess an aspinose body but spinose cuticle (Pandey and Agrawal, 2013). *Clinostomoides rai* was proposed by Rai (1970) (later revised by Pandey, 1974) for metacercariae from the intestine of *Clarias batrachus* collected in Mathura, on the basis of distance between suckers and limbs of uterus (Pandey and Agrawal, 2013). However, Pandey and Agrawal (2013) appear to have mistranscribed morphological values (i.e. acetabulum

1.16 x 0.78 mm vs acetabulum at distance of 1.16 mm behind anterior end of body and 0.78 mm in diameter) and host tissues (muscle vs intestine) recorded by Rai (1970).

Clinostomoides meerutensis Pandey and Tyagi, 1986 and *C. pandeyii* Singh and Sharma, 1994, were both created for metacercariae from the body surface of *H. fossilis* in Meerut based on a spinose tegument and ovary opposite to cirrus sac. Pandey and Kiran (2002) synonymized *C. rai*, *C. meerutensis* and *C. pandeyii* with *C. dollfusi*. *Clinostomoides baughi* Pandey, 1998 was described from metacercariae in skin near the operculum of *H. fossilis* in Lucknow, based only on comparisons with the species of Indian *Clinostomoides* mentioned above. In the descriptions of *C. meerutensis*, *C. pandeyii* and *C. baughi*, the ovary is described as opposite to the cirrus sac. However, to our knowledge the ovary in the genus *Clinostomoides* and/or *Clinostomum* is always on the same side as the cirrus pouch. Line drawings in Pandey and Agrawal (2013) appear to show specimens of the latter three species transposed, with the uteroduct in the right side of the body.

In our opinion, these species of *Clinostomoides* (*C. dollfusi*, *C. rai*, *C. chauhani*, *C. meerutensis*, *C. pandeyii*, *C. baughi*) described from India are *species inquirendae* because the morphological basis of each may be an artifact of development, beginning with the comparison of larval *C. dollfusi* with adult *C. brienii* and cascading through later descriptions. The characters considered in these studies vary with parasite development and may also be influenced by fixation and mounting (Manter and Pritchard, 1969; Fischthal and Thomas, 1970). Until such species can be verified through morphological comparisons at equivalent stages of development, preferably with detailed accounts of the genital complex and with supporting molecular data, we consider only *Clinostomum brienii* to be valid. Essentially, this view follows Manter and Pritchard (1969) and Fischthal and Thomas (1970). Further work may reveal additional species of *Clinostomum* with the *Clinostomoides*-morphotype on the Indian subcontinent or elsewhere, but currently this is supported with neither molecular (Figs.

1, 2) nor morphological data. Connectivity between Indian and African populations of *C. brienii* could be maintained by species of *Ardea* which occur in both regions (e.g., *A. cinerea*, *A. purpurea*, *A. goliath*, BirdLife International, 2018).

ACKNOWLEDGEMENTS

The authors are grateful for the support of Professor A. Chocha Manda (Université de Lubumbashi, R.D. Congo) and for constructive suggestions made by two anonymous reviewers.

FINANCIAL SUPPORT

Part of the research done in South Africa by AH was supported by the South African Research Chairs Initiative of the Department of Science and Technology and National Research Foundation (NRF) of South Africa (Grant No 101054). Any opinion, finding and conclusion or recommendation expressed in this material is that of the author(s) and the NRF does not accept any liability in this regard. SL was supported by the Puerto Rico Science Technology & Research Trust. MC, DB, TP and MLF received no specific grant from any funding agency, commercial or not-for-profit sectors.
