### **ABSTRACT**

This work investigated the suitability of the cryotolerant yeast *Saccharomyces eubayanus* to 28 ferment Chardonnay must at different temperatures ( $10^{\circ}$ C,  $12^{\circ}$ C,  $16^{\circ}$ C, and  $26^{\circ}$ C) over two vintages (2013 and 2014). The effect of added nitrogen was also evaluated. The strain's fermentation parameters (maximum growth rate, lag phase, and asymptotic maximum) and cell growth were compared to the values for two reference *Saccharomyces cerevisiae* strains. *Saccharomyces eubayanus* showed its best fermentation performance at low temperatures (10°C and 12°C), with optimal kinetic parameters and high sugar consumption. Moreover, wines from the cryotolerant yeast showed a volatile acidity reduction of approximately 50%, and a 9% increase in total polyphenols, compared to the reference yeasts. At 16°C the cryotolerant and control yeasts performed quite similarly, whereas at 26°C the former displayed stuck fermentation. For both yeasts, at 10°C the nitrogen content did not affect maximum growth rate, whereas it did at 16°C. Sensory analyses were run on the 2014 trials, showing differences in color, sweetness, and overall liking among wines obtained at 10°C, whereas wines obtained at 16°C differed only in color. Results demonstrate for the first time the *Saccharomyces eubayanus* suitability for low-temperature fermentation in white wine production, potentially enriching yeast biodiversity in winemaking. imal kinetic parameters and high sugar consumption. Moreoved a volatile acidity reduction of approximately 50% compared to the reference yeasts. At  $16^{\circ}$ C the cryotoler milarly, whereas at  $26^{\circ}$ C the former displaye

### **Introduction**

Sensory properties of wine depend on grape variety, technology, and secondary metabolites produced by microbiota during fermentation (Andorrà, Berradre, Mas, Esteve-Zarzoso, & Guillamón, 2012; Englezos, Rantsiou, Cravero, Torchio, Giacosa, Ortiz-Julien, et al., 2018; Molina, Swiegers, Varela, Pretorius, & Agosin, 2007). There are two approaches to exploiting the role of microbiota to improve wine's sensory characteristics. In the first approach, low temperatures are applied during wine fermentation to improve the stability and excretion of volatile compounds (Killian & Ough, 1979; Torija, Beltran, Novo, Poblet, Guillamón, Mas, et al., 2003), enhancing the aroma complexity of white wines (Beltran, Novo, Guillamón, Mas, & Rozès, 2008; Deed, Fedrizzi, & Gardner, 2017; Pérez, Assof, Bolcato, Sari, & Fanzone, 2018; Rollero, Bloem, Camarasa, Sanchez, Ortiz-Julien, Sablayrolles, et al., 2015; Torija, et al., 2003). The second approach is based on selecting yeasts capable of providing great complexity in terms of aroma, taste, and structure (Maturano, Lerena, Mestrea, Casassa, Toro, Vazquez, et al., 2018; Patrignani, Montanari, Serrazanetti, Braschi, Vernocchi, Tabanelli, et al., 2017; Pretorius, 2000). Combining both approaches represents an opportunity worthy of investigation. S*accharomyces cerevisiae* is the species that has been selected for the starter culture, due to its resistance to the stressful conditions of fermentation (high sugar concentration, ethanol, and temperature and low pH) (Degre, 1993; Reed & Nagodawithana, 1988). However, its inability to lead fermentation at low temperatures can cause delayed (and, sometimes, stuck) sugar consumption. As a result, interest in cold-tolerant yeasts which also improve wine characteristics such as aroma and taste has been growing. Of particular interest is *Saccharomyces eubayanus* CBS 12357 (hereafter referred to as EU), isolated from natural sources in Patagonia (Libkind, Hittinger, Valério, Gonçalves, Dover, Johnston, et al., 2011). Studies performed on EU in the grape juice and brewing sectors showed incomplete sugar consumption (Alonso-del-Real, Lairón-Peris, Barrio, & Querol, 2017; Gibson, Storgårds, Krogerus, & Vidgren, 2013) owed to fermentation stressors (Origone, del Mónaco, Avila, González Flores, Rodríguez, & Lopes, 2017). However, successful apple juice fermentation and cider production 279; Torija, Beltran, Novo, Poblet, Guillamón, Mas, et al.<br>
of white wines (Beltran, Novo, Guillamón, Mas, & Rozès,<br>
Pérez, Assof, Bolcato, Sari, & Fanzone, 2018; Roller<br>
en, Sablayrolles, et al., 2015; Torija, et al., 200

have been reported (González Flores, Rodríguez, Oteiza, Barbagelata, & Lopes, 2017). Other studies demonstrate the ability of a closely related strain, *Saccharomyces eubayanus* NPCC 1285, to ferment under low-nitrogen and low-temperature (i.e. 12°C) conditions (Magalhães, Krogerus, Castillo, Ortiz-Julien, Dequin, & Gibson, 2017a; Su, Origone, Rodríguez, Querol, Guillamón, & Lopes, 2019). However, these studies mostly investigated on nitrogen requirements or selected new interspecies hybrid strains and were often performed on synthetic must only.

In this study, we evaluated the potential of *Saccharomyces eubayanus* CBS 12357 (EU) to enlarge yeast availability in winemaking. The evaluation consisted of fermenting Chardonnay musts at 83 different temperatures (10<sup>o</sup>C, 12<sup>o</sup>C, 16<sup>o</sup>C, and 26<sup>o</sup>C), with and without nitrogen supplement, in two vintages (2013 and 2014). The performance of EU was compared to two commercial strains *Saccharomyces cerevisiae bayanus and Saccharomyces cerevisiae* used in winemaking worldwide. maximum in the evaluation consisted of fermenting<br>

### **2. Materials and Methods**

### **Grape and Yeast Strains**

The study was carried out on two vintages of Chardonnay grape must: a 2013 vintage from Cesena (44°14'W, 12°15'S) and a 2014 from Riolo Terme (44°29'W, 11°71'S), both in Emilia Romagna (Italy). The grapes were harvested manually and immediately transported to the winery for destemming and pressing. The juice was settled at 4°C for 24 h. The 2013 must's chemical characteristics were: Babo (soluble solids) 18.0 g/100g, pH 3.25, titratable acidity 8.3 g/L, and assimilable nitrogen 140 mg/L (no nitrogen was added). Babo is a unit measurement to express soluble solids (g/100 g). Soluble solids in must are ~95% sugars. The measurement allows to monitor the fermentation by the reduction of density (from sugar to alcohol). It is the main method used in the small/medium size wineries. The chemical characteristics of the 2014 must were: Babo (soluble solids g/100g) 16.7, pH 3.37, titratable acidity 7.5 g/L, total sulfur dioxide 40 mg/L, and assimilable nitrogen 110 mg/L (supplemented to achieve 160 mg/L before fermentation).

For the 2013 vintage, we compared the cryotolerant *Saccharomyces eubayanus* CBS 12357 (*EU*: Westerdijk Fungal Biodiversity Institute, Utrecht, Nederlands) to S*accharomyces cerevisiae bayanus* QA23 (*CB*: Lalvin, Canada), which optimally ferments white must between 15°C and 26°C. For the 2014 vintage, being the temperatures of investigation restricted at 10°C and 16°C, we compared EU to *Saccharomyces cerevisiae* VIN13 (*CE*: Anchor, South Africa), a relatively 105 cryotolerant strain with an optimal temperature range of  $12-16^{\circ}$ C and nitrogen requirements.

### **Inoculum preparation**

Yeasts were grown in 1-L flasks containing 300 mL YPD growth medium (1% yeast extract, 2% peptone, and 2% dextrose; Thermo Fisher Scientific, Monza, Italy). The flasks were incubated overnight at 28°C and shaken at 200 rpm. Before inoculation, the precultures were centrifuged at 6000 g for 10 min and the resulting pellet was resuspended in Chardonnay must, previously heat-treated at 60°C for 15 min. A cell concentration of 6.0 Log CFU/mL was used to inoculate all vinification trials. tion<br>

and the resulting pellet was resuspended in Chard

### **Fermentation conditions**

In 2013, each strain was tested at three temperatures (12°C, 16°C, and 26°C), in either 3-L capacity flasks containing 2 L (for EU: *Saccharomyces eubayanus*) or 1-L capacity flasks containing 0.65 L (for CB: S*accharomyces cerevisiae bayanus*) of must: 2 EU trials and 1 CB trial for each temperature were carried, for a total of 9 trials (**Table 1**). In 2014, the temperature was either 10°C or 16°C and the effect of added assimilable nitrogen (N: di-ammonium phosphate, 50 mg/L) on strain fermentation performance was studied. Fermentations were performed in duplicate in 5-L flasks containing 3 L of must for both EU and CE: 2 strains x 2 temperatures x 2 N conditions were carried out in duplicate for a total of 16 trials (**Table 1**). The N source was added when the must density was 1060 (ca. 3% alcohol). In both vintages, the must was flash-pasteurized (60°C for 15 min), then inoculated to a concentration of 6.0 Log CFU/mL. The flasks were equipped with Müller

126 valves for  $CO_2$  release without oxygen intake. The fermentations, monitored daily by measuring the weight loss of each flask, were considered completed when the weight was unchanged for four 128 consecutive days. Kinetic parameters (μ<sub>max</sub>: maximum specific growth rate (day <sup>-1</sup>), λ: lag phase 129 period (day), and  $Y_{end}$ : asymptotic maximum (g/L)) were calculated from each fermentation curve, 130 which was created by relating weight loss  $(g/L)$  to fermentation time (days) and fitted by a non-linear regression (Baranyi & Roberts, 1994). With the exception of the 2013 CB trials, which were carried out singly due to the yeast's well-documented technological performance (Blanco, Mirás-Avalos, Pereira, & Orriols, 2013), all of the trials were run in duplicate; data are presented as average values. After fermentation, the wines were cold–settled (4°C) for a week, then racked. Potassium metabisulphite was added to achieve 100 mg/L of total sulphure dioxide. After bottling, wines were stored at 4°C until chemical, sensory, and aroma analyses were performed. Orriols, 2013), all of the trials were run in duplicate;<br>ter fermentation, the wines were cold-settled (4°C) for<br>alphite was added to achieve 100 mg/L of total sulphure c<br>t 4°C until chemical, sensory, and aroma analyses

### **Sampling yeast growth kinetic**

Throughout the fermentation, serially diluted samples from each flask were used to inoculate YPD agar plate (1% yeast extract, 2% peptone, 2% dextrose, 1.8% agar; Thermo Fisher, Monza, Italy) for cell growth the number of viable yeast cells was determined by counting colony-forming units (CFU/mL) after the plates were incubated at 25°C for 48 h. Starting at inoculation, one mL from each flask was sampled every few days (vintage 2013: days 0, 4, 6, 11, and 18; vintage 2014: days 0, 1, 5, 9, 12, 15, 19, and 26). Three repetitions for each sampling were carried out on both vintages for the trials without nitrogen. The kinetic parameters  $\mu_{\text{max}}$ : maximum specific growth rate (day <sup>-1</sup>),  $\lambda$ : lag phase period (day), and Y<sub>end</sub>: growth/asymptotic maximum (Log CFU/mL) were calculated by relating cell load (Log CFU/mL) versus time (days) and fitting a non-linear regression (Baranyi & Roberts, 1994).

### **Wine parameters analysis**

The wines were analyzed for alcohol content (AC), pH, total acidity (TA), dry matter (DM), volatile acidity (VA), color at 420 nm (CO), and total polyphenols at 280 nm (TP), using official European 153 methods (EU, 1990). Moreover, total  $(SO_{2T})$  and free  $(SO_{2F})$  sulphur dioxide (Ripper & Schmitt, 1896) as well as residual sugars (RS) (Lane & Eynon, 1923) were quantified.

## **Wine volatile molecule profiles**

The volatile profiles of the wines were analyzed by headspace solid phase microextraction (HS−SPME, CAR/PDMS, 65 µm, SUPELCO, Bellefonte, PA), coupled with gas chromatography mass spectrometry (GC−MS, Agilent 7890 A, Agilent Technologies, PA) equipped with a Varian 50m x 0.25 µm column (Bruker Optics Inc., Billerica, MA). The internal standard was 4-methyl 2- penthanol (100 mg/L). The analysis followed the method proposed by Patrignani et al. (2017). Volatile molecules were identified by referencing NIST 2.0 (US National Institute of Standards and Technology) and Wiley 7 libraries. PDMS, 65 µm, SUPELCO, Bellefonte, PA), coupled wit<br>(GC–MS, Agilent 7890 A, Agilent Technologies, PA) equals<br>(GC–MS, Agilent 7890 A, Agilent Technologies, PA) equals<br>(Dumn (Bruker Optics Inc., Billerica, MA). The internal s

### **Wine sensory analysis**

For the evaluation of the 2014 vintage wines, twenty-two judges (10 women, 12 men) were recruited from students trained in winemaking and sensory evaluation who were enrolled in the Viticulture and Enology course, University of Bologna (Cesena, Italy). The number of judges was consistent with the minimum suggested for the two selected sensory tests (Lawless and Heymann 1998; Heymann, Machado, Torri & Robinson, 2012). First, a triangle test (ISO, 2004) was performed to disclose any significant differences between replicates. Afterwards, a descriptive analysis of color (intensity, likeability), aroma (flower, fruit, alcohol, overall aroma), taste (sweet, sour, bitter/astringent, alcohol, overall taste), body, persistence, and overall likeability was carried out (Lawless and Heymann 1998). Thirty-mL coded samples were presented in fully randomized order at room temperature (20°C) in 170-mL tulip glasses (ISO, 1977) covered with plastic dishes to preserve aroma. Transparent glasses for color evaluation and black glasses for other descriptors'

evaluation were used. Judges were allowed to rinse their mouths by drinking water between samples. In the descriptive analysis, samples were scored on a 10-point scale anchored with "absent" and "high" intensity. Tasting sessions took place in a facility equipped with individual sensory booths illuminated with daylight lamps (ISO, 2007); two sessions were set up, with eight wines assessed during each session.

## **Statistical analysis**

Values of weight loss parameters and chemical data (from analyses of vinifications carried out in duplicate), and cell growth parameters (from three repetitions of trials without nitrogen supplementation), are presented as mean±standard deviation (SD). The one-way and two-way analyses of variance (ANOVA; significance p ≤0.05), Fisher *post-hoc* test, and spider plot representations of sensory profiles were performed using XLSTAT version 2011.1.05 (Addinsoft, Anglesey, UK). The DMFit package (Baranyi & Roberts, 1994) was used for the regression analyses of fermentation kinetics and yeast cell growth data. For the sensory triangle test, the data were analyzed with 95% confidence intervals. by parameters and chemical data (from analyses of vinit<br>

### **3. Results and Discussion**

- *3.1. 2013 Vintage*
- *3.1.1. Fermentation Kinetics and Yeast Cell Growth*

At each temperature (12°C, 16°C, and 26°C), the fermentation kinetics (represented by daily weight loss) and the cell growth data for the two strains (EU and CB) were fitted by non-linear regression (see **Figure 1**). Both curves were considerably affected by temperature. At 12°C, EU showed less weight loss and a higher cell load than CB (**Figure 1a**), whereas at 26°C the CB strain recorded more weight loss then EU, but similar cell load (**Figure 1c**). The EU strain's cell numbers were 201 lower at  $26^{\circ}$ C than at 12 $^{\circ}$ C, which could be related to impaired cell membrane functionality caused by a decrease of unsaturated fatty acids and an accumulation of ethanol (Torija, et al., 2003;

Beltran et al., 2008; Pérez et al., 2018). The sensitivity of *Saccharomyces eubayanu* to ethanol has, in fact, been shown to increase with temperature (Magalhães et al., 2017a). At the intermediate temperature of 16°C, the cell loads were similar and the weight losses achieved the minimum difference (**Figure 1b**).

In both strains (see **Figure 1**), the stationary phase began after 23 days at 12°C and after 12 days at 16°C. At 26°C, EU stopped losing weight after seven days due to sluggish/stuck fermentation and there was a slight decrease in yeast viability after 11 days; however, CB did not stop losing weight until the 21st day.

211 For cell growth, all quantitative parameters achieved good fit (see  $R^2$  values, **Table 2**). The lowest 212 value for the  $\mu_{\text{max}}$  of EU (0.32 day<sup>-1</sup>) was recorded at 26°C and for that of CB (0.20 day<sup>-1</sup>) at 12°C; 213 the highest  $\mu_{\text{max}}$  value for EU (0.43 day<sup>-1</sup>) occurred at 12<sup>o</sup>C and for CB (0.50 day<sup>-1</sup>) at 16<sup>o</sup>C. These 214 results support the findings that characterize EU as cryotolerant (Libkind et al., 2011; Peris et al., 215 2016). No lag phase was detected in any trial, perhaps due to the three-day interval between the first 216 two samplings. For the EU strain, the asymptotic maximum ( $Y_{\text{end}}$ ) was proportional to  $\mu_{\text{max}}$ , with 217 higher values at  $12^{\circ}$ C (7.7 Log CFU/mL) and lower values at  $26^{\circ}$ C (7.1 Log CFU/mL), confirming 218 the suitability of this yeast for low-temperature fermentation. quantitative parameters achieved good fit (see  $R^2$  values,<br>f EU (0.32 day<sup>-1</sup>) was recorded at 26°C and for that of CI<br>ue for EU (0.43 day<sup>-1</sup>) occurred at 12°C and for CB (0.50<br>findings that characterize EU as cryotole

219 For weight loss, wide differences were found in the quantitative parameters, depending on the 220 growth temperature (**Table 2**). A direct proportional relationship between  $\mu_{\text{max}}$  and temperature was 221 observed for EU; in fact, the former rose from 3.6 to 15.1 day<sup>-1</sup> when the latter increased from  $12^{\circ}$ C 222 to 26<sup>o</sup>C. However, at 26<sup>o</sup>C, the Y<sub>end</sub> was low (59.1 day<sup>-1</sup>) due to stuck fermentation (**Table 2**). At 223 16°C, the  $\mu_{\text{max}}$  of the EU strain (8.2 day<sup>-1</sup>) was similar to that of CB (9.9 day<sup>-1</sup>), which demonstrated 224 higher Y<sub>end</sub> at any temperature. At 12<sup>o</sup>C, EU fermentation was characterized by a lower  $\mu_{\text{max}}$  (3.6 225 day<sup>-1</sup>) and Y<sub>end</sub> (79.7 g/L) compared to CB. However, EU adapted quickly to the low growth 226 temperature, while CB showed a 1.3-day lag phase.

- 227
- 228 *3.1.2. Wine Characteristics*

The final compositions of the EU and CB wines are shown in **Table 3**. No significant differences were found for free sulphur dioxide or pH. However, all EU wines, regardless of temperature, had more residual sugars (range: 6.0−15.6 vs 1.0–1.3 g/L) and consequently, lower alcohol content (range: 10.0−10.7 vs 11.9−13.0 %) than CBs. Highest residual sugar and lowest alcohol content 233 occurred in one of the two 26<sup>o</sup>C replicates due to stuck fermentation. Low temperature determined a significant decrease in volatile acidity (VA) in EU wines compared to CB wines. At all temperatures, the color intensity was lower for EU than CB wines.

*3.2. 2014 Vintage* 

# *3.2.1. Fermentation Kinetics and Yeast Cell Growth*

The combined effects of temperature (10°C, 16°C) and nitrogen supplementation were compared for the EU strain and a commercial *Saccharomyces cerevisiae* strain (CE) (**Figure 2**).

Interestingly, the weight loss and cell load were similar at both temperatures for the EU strain; 242 however, at 16<sup>o</sup>C the fermentation was faster and the stationary phase was reached five days earlier. 243 Compared to the commercial yeast CE, at  $10^{\circ}$ C the EU strain showed faster sugar consumption (correlated with a higher cell load) and entered the stationary phase earlier (**Figure 2a**). At 16°C, the two yeasts' weight losses were similar (**Figure 2b**)—as in the 2013 vintage; however, EU entered the stationary phase after ten days, two days before CE. The maximum cell load was not affected by temperature for either strain, but EU reached a higher population than CE. Note that the nitrogen supplement did not affect weight loss for any fermentations, indicating that the must's initial nitrogen concentration (110 mg/L) was enough to permit suitable development of both yeasts: specifically, nitrogen was not a limiting factor. *Kinetics and Yeast Cell Growth*<br>ts of temperature (10°C, 16°C) and nitrogen supplemen<br>d a commercial *Saccharomyces cerevisiae* strain (CE) (**Fig**<br>reight loss and cell load were similar at both temperatu<br>e fermentation w

251 For cell growth, the maximum growth rate  $(\mu_{max})$  and the asymptotic maximum  $(Y_{end})$  were

significantly higher for EU at both temperatures **(Table 2**). In particular, the highest μmax was

253 recorded for EU at  $10^{\circ}$ C (2.8 day<sup>-1</sup>) and  $16^{\circ}$ C (2.9 day<sup>-1</sup>), whereas CE was almost 3.5 slower

254 regardless of temperature. Satisfactory model fitting  $(R^2)$  was achieved for every model.

255 Weight loss (**Table 2**), quantified by  $\mu_{\text{max}}$  and  $Y_{\text{end}}$ , was unaffected by strain or nitrogen supplement 256 at 10<sup>o</sup>C, whereas at 16<sup>o</sup>C nitrogen did increase the  $\mu_{\text{max}}$ , but not the Y<sub>end</sub>, of both strains. Thus, 257 nitrogen would improve the maximum growth rate of EU at  $16^{\circ}$ C, but not at  $10^{\circ}$ C, confirming its suitability for low temperatures. A decrease in the amount of ammonium required for low-temperature fermentation has previously been reported (Beltran et al., 2008; Pérez et al., 2018);

possible causes include a diminution of permease activity due to decreased membrane fluidity or a

261 change in nitrogen catabolite repression. For CE strain at  $10^{\circ}$ C a lag phase ( $\lambda$ ) of 1.1 and 1.3 days

with or without nitrogen supplementation, respectively, was recorded.

### *3.2.2. Wine Characteristics*

At both temperatures, the alcohol content, pH, and dry matter were similar for both yeasts **(Table 4)**; however, volatile acidity, a parameter related with impaired wine quality, was almost twice as high for CE. For both UE and CE, the free sulphur dioxide content was similar, while total sulphur dioxide was higher in EU, probably due to its combination with aldehydes (Frivik & Ebeler, 2003)., Total polyphenols were significantly predominant in all EUs, regardless of temperature; previous research has reported yeast-specific variations in polyphenol concentrations (Le Bourvellec & Renard, 2012; Nguela, Poncet-Legrand, Sieczkowski, & Vernhet, 2016). At 10°C, the total acidity, residual sugars, and color were similar. In EUs, residual sugars were higher at 16°C than at 10°C, confirming the yeast's ability to ferment better at low temperatures. The color of EU was also higher at the highest temperature. Nitrogen had no effect on any parameter at either temperature. ogen supplementation, respectively, was recorded.<br>
teristics<br>
es, the alcohol content, pH, and dry matter were similar the<br>
de acidity, a parameter related with impaired wine quality<br>
th UE and CE, the free sulphur dioxide

## *3.2.3. Quantification of Volatile Compounds*

The EU wines presented a high concentration of total alcohols and esters, whereas the CE wines had a high content of volatile acids (**Table 5**); moreover, the concentration was unaffected by fermentation temperature or nitrogen supplement. No significant interaction between strain and nitrogen was detected; this result is supported by a previous study (Magalhães et al., 2017a)

performed on Sauvignon blanc wine produced with the interspecies hybrid *Saccharomyces cerevisiae x Saccharomyces eubayanus*. The differences in detected volatile compounds for EU and CE yeasts fermenting at 10°C and 16°C are reported in **Table 5**. The yeast had a significant effect on the synthesis of most of the compounds, whereas nitrogen addition (N) and interactions (YS\*TM, TM\*N, YS\*N) affected to a less extent. Among the detected compounds with sensory thresholds available in the literature, sixteen were present with an odor activity value (OAV: 287 concentration divided by sensory threshold)  $\geq$ 1. In the EU wines, 2-phenethyl alcohols (rose aroma) reached the highest OAV value compared to other aromatics, regardless of the temperature. Among esters, the ethyl nonanoate (nut, rose) was detected in EU wine only, with a higher OAV in the wine fermented at 16°C. The ethyl decanoate (fruit, grape) displayed an opposite trend in EU and CE wine at both temperatures. Ethyl myristate (floral) was detected only in EU wine produced at 10°C, whereas methyl myristate (floral, orris) was produced at the highest concentrations by both yeasts at 16°C. As expected from manufacturer information, CE wines reached high concentrations of ethyl hexanoate (apple, pineapple) and octanoic acid (fruit) with OAV in the interval 6237–10471. 295 Isoamyl octanoate, (fruit) was found only in EU and CE wines at  $10^{\circ}$ C. At  $10^{\circ}$ C the EU strain produced less ethyl acetate (which has negative aroma characteristics) than the CE strain. Interestingly, EU wines were also characterized by a higher concentration of phenethyl acetate (rose) than CE wines at both temperatures; this aromatic compound is considered a marker in fermentation performed with *Saccharomyces eubayanus* (Magalhães et al., 2017a; Magalhães, Krogerus, Vidgren, Sandell, & Gibson, 2017b). Isoamyl acetate (banana, fruit) was the dominant compound for CE wines at both temperatures; this result was expected, since the strain has been genetically selected to prioritize ester production (reaching highest level at 16°C). For EU wines, 303 the concentrations of this compound were comparable to CE wines at  $10^{\circ}$ C (regardless the nitrogen supplementation) and at 16°C without nitrogen supplementation, supporting previous findings that high isoamyl acetate production occurs at low temperatures (Killian & Ough, 1979; Molina et al., 2007). OAV value compared to other aromatics, regardless of th<br>anoate (nut, rose) was detected in EU wine only, with a hi<br>The ethyl decanoate (fruit, grape) displayed an opposite<br>atures. Ethyl myristate (floral) was detected onl

### *3.2.4. Sensory Analysis*

A preliminary discriminatory triangle test demonstrated that the replicates were not significantly different. Consequently, one replicate of each wine was randomly selected for sensory descriptive analysis; the results are represented as spider plots. At 10°C **(Figure 3a)**, the highest color intensity scores, positively correlated to color liking, were obtained in CE wines. These wines also scored higher than EUs for sweetness and overall liking. There were no significant differences for the remaining olfactory and taste descriptors.

At 16°C (**Figure 3b**), CE wines were again scored higher than EUs for color liking. Unlike at 10°C, the sweetness was similar for both wines. Moreover, overall liking and all other sensory descriptors were not significantly different; the EU wines were comparable to the CEs. However, the fruit notes differed: the exotic fruit notes (banana, apple) were the key sensory aromas of CE wines, whereas the EUs were scored higher for floral notes (e.g., rose). This result reflects the predominant OAVs. and taste descriptors.<br>
(a), CE wines were again scored higher than EUs for color is<br>
imilar for both wines. Moreover, overall liking and all oth<br>
ly different; the EU wines were comparable to the CEs. H<br>

### **4. Conclusions**

*Saccharomyces eubayanus* demonstrated an ability to adapt to low-temperature fermentation environments, obtaining the best kinetic parameters at 10°C and 12°C, whereas at 26°C stuck fermentation are possible. At 16°C it performed similarly to *Saccharomyces cerevisiae/bayanus c*ommercial yeasts.

From a biotechnological point of view, wines obtained using this cryotolerant yeast showed good 328 chemical characteristics in fermentation carried at  $10^{\circ}$ C, 12 and 16 $^{\circ}$ C, whereas the main differences were disclosed for sensory characteristics, especially in fermentation carried out at the lowest temperature (10°C). Nitrogen addition slightly boosted the maximum growth rate at 16°C, but did not affect the wines' other kinetic parameters or chemical characteristics, thus demonstrating this

yeast's low nitrogen requirement. In *Saccharomyces eubayanu*s wines a higher concentration of

volatile compounds, responsible for floral and white fruit notes, were detected.

In conclusion, *Saccharomyces eubayanus* adapted to the stress of low temperatures and started 335 fermentation quickly. For most of the available commercial yeasts,  $10-12^{\circ}$ C is an extremely low fermentation temperature range.

The chemical and sensory characteristics of the obtained wines make this yeast worthy of further investigation for production of wine with low pH and light color, such as base wine for sparkling wines. This development would expand the biodiversity of winemaking yeasts capable of producing quality wines. MENTS<br>

Journal Prejactor

- *S. eubayanus* showed good adaptation to low temperature and wines were characterized by low volatile acidity.
- Nitrogen requirements of commercial and cryotolerant strains were similar.
- *S. eubayanus* wines were characterized by 2-phenethyl alcohols (rose aroma) whereas *S. cerevisiae* by ethyl hexanoate (apple, pineapple).
- The cryotolerant yeast *S. eubayanus* is a valuable alternative to conventional yeast in the production of base wine for sparkling wines.
