## Highlights

- Hemp seed bran is an ~~unexploited-untapped~~ food source for human consumption
- ~~P~~The prebiotic ~~potential~~activity is studied ~~coupling~~was studied analyzing microbial growth-microbiology- and bioactives production
- A bacterial pool fermented better hempseed bran than single bacterial speciesThe best fermentations of hemp seed bran are those made with a bacterial pool.

• Volatile SCFAs and terpenes of bran are increased with lactobacilli fermentation

• Fermentation improves prebiotic potential of hemp seed bran

## Abstract

Plant-based feedstock nutritionally and functionally rich are evermore requested in the food industry, although sustainability is a must. An untapped and sustainable source is hemp seed bran (HPB), which is a byproduct of industrial hemp seed flour. ~~This research concerns over the exploration of prebiotic activity of hemp seed bran and its exploitation throughout fermentation by beneficial lactobacilli.~~ In this research we have studied the fermentation of HPB with different beneficial bacteria with the intention to valorize ~~Its aim is to shed light on hemp seed bran~~ HPB for further food applications as a fiber supplement ~~in foods~~. Prebiotic activity was tested *in vitro*, and microbiological features were monitored and studied, as fermentation process and release of volatile organic compounds (VOCs). ~~The assessment of its prebiotic activity, investing over bacterial growth and prebiotic related volatilome, r~~ Results ~~ed~~ indicate that fermentation is able to ~~higher~~ scores with fermentation by increment ~~in~~ increase terpenes and organic acids of HPB, particularly when is conducted by a bacterial pool. Besides, *p*-Cymene, Myrcene, and Eugenol ~~were are those~~ the VOCs ~~compounds~~ majorly correlated to prebiotic activity. ~~Though the hemp seed value is well known, Although other studies must be conducted, wealthy byproducts hitherto scarcely studied should be valorized, and this~~ this paper suggests that HPB should be valorized as a substrate ~~work~~ ~~vows to provide some basics~~ to produce sustainable and chemical free prebiotics.

## 1. Introduction

Hemp (*Cannabis sativa* subsp. *sativa*) is the ~~non drug~~-variety ~~with no and contains legal content of~~ psychotropic ~~agent effect~~ (Korus, Witzak, Ziobro & Juszczak, 2017). The food products derived are steering a large sector market that is constantly rising worldwide ~~up to. The global sector expected to generate around~~ USD 4.89 billion by 2026 ~~(at a CAGR (Compound Annual Growth Rate) of around 6.2% between 2019 and 2026~~ (Zion Market Research 2018). This high rise is due to the ease on ~~legal~~-restraints for registered varieties with no psychotropic effect, considering plants cultivation and transformation and consumption of derived products. The feedstock principally exploited in the hemp food industry are the seeds, that are free of cholesterol, are rich in proteins, vitamins, and minerals, are plenty of dietary fibers and bioactives (Hartsel, Eades, Hickory & Makriyannis, 2016; Wang, Jiang & Xiong, 2018; El Sohly, Radwan, Gul, Chandra & Galal, 2017) and do not contain any psychotropic agent. ~~Hemp seeds are rich in T~~erpenes ~~of hemp have with outstanding~~-antioxidant activity (Frassinetti et al., 2018) and ~~their use is regulated as are~~ flavor and fragrance components generally regarded as safe (GRAS) ~~by several regulatory agencies~~ (Hao, Gu & Xiao, 2015). Hemp seeds ~~are transformed in flour is that is principally produced used~~ for human consumption, while the proteinaceous cake is used for animal feeds, ~~and t. Whatever the industrial process, the derived bran is a byproduct mainly discarded, but possibly represents a high value material to suit~~still valid for further food applications. A specific address could be that of prebiotics. The current definition is stating that “a prebiotic is a substrate that is selectively utilized by host microorganisms conferring a health benefit” (Gibson et al., 2017), and this version enlarged the concept to other compounds than traditional polysaccharides. Consequently, complex substrates as

dietary fibers, that bring and liberate or serve for the gut microbiota to generate different bioactive molecules ~~such as~~ (short chain organic acids or terpenes), could attain to this new description. The para prebiotic activity of some fibers could be improved with *in vitro* fermentation by beneficial bacteria. This strategy permits to obtain a product with Besides, it is important to consider that fermentation by lactobacilli improves the quality of the final product substantially over two aspects: firstly, the deconstruction of the fiber liberates other compounds, such the so-called postbiotics, that improves the prebiotic potential of the original product, while secondly the yield and more bioactives and to improve their bio accessibility of many different bioactives (polyphenols and terpenes) resulted augmented. These bacteria are able to ferment plant-based matrices generating and transforming metabolites. For instance, when ~~Lacticaseibacillus rhamnosus~~ *Lactobacillus rhamnosus* LGG is applied in combination and different with two *Lactiplantibacillus plantarum* ~~subsp. plantarum~~ *Lb. plantarum* isolates to ferment plant-based products, improves the content of phenols and flavonoids of blueberry pomace (Yan et al., 2019). In fact, the enzymatic arsenal of lactobacilli, such as that of ~~Strains of *Lp. plantarum*~~ *Lb. plantarum*, *Lc. rhamnosus* ~~*Lb. rhamnosus*~~, and *Limosilactobacillus fermentum* improve the content of bioactives of hemp seed products ~~*Lb. fermentum*~~ perfectly conveys them for fermentation of plant-based matrices (Nissen, Demircan, Taneyo-Saa & Gianotti, 2019; Nissen, di Carlo & Gianotti, 2020). Additionally, these species are beneficial, and some related strains own the claim of probiotics, as ~~*Lb. rhamnosus* GG~~ (LGG), *Lp. plantarum* ~~*Lb. plantarum*~~ K10, and *Lm. fermentum* ~~*Lb. fermentum*~~ ME-3 (Darby, Naudin, Luo & Jones, 2019; Kim, Huang, Park, Holzapfel & Lim, 2018; Nowak, Paliwoda & Błasiak, 2019). Up today, no works were conducted exploring the functional properties of hemp seed bran (HPB) after fermentation. Due to this reason, we made ~~This work~~ with the intention to explored characterize and valorize ~~hemp seed bran~~ HPB (HPB) potential functionalities as a consequence of LAB (lactic acid bacteria) fermentation. by coupling its We aimed to achieve this goal by coupling prebiotic activity to the release of potential ~~volatile organic~~ bioactives volatile organic compounds (VOCs) as a consequence of LAB fermentation: i), such as low organic acids, coming

directly from microbial metabolism postbiotics produced by LAB fermentation, and ii) terpenes, more related to intrinsic compounds of hemp seed bran matrix compounds modification. We have compared HPB to a positive control, i.e. fructooligosaccharides (FOS) from chicory, as the most renowned prebiotics. This work wants to give more details on the valorization of HPB for food applications that resulted still unexplored novelty of this work has to be found in the byproduct tested, that up to now results poorly characterized (Setti et al. Samaci, Maggiore, Nissen, Gianotti & Babini, 2020) employing emerging approaches to study, improve, and highlight and on the methodology used to assay prebiotic activity, the prebiotic potential of HPB based on a combination of molecular methods to quantify bacterial cells and bioactive VOCs.

## 2. Materials and methods

### 2.1. HPB-Hemp seed bran preparation

HPB, a byproduct remaining after mechanical pressing of hemp seeds and subsequent grinding and sieving, was supplied by a local company (Hemp Positive World, Cesena, Italy). Original hemp variety was Futura 75. Five grams of HPB were suspended in 30 mL of distilled water, sterilized (121 °C and 100 kPa for 20 min) (Vapor Matic 770, ASAL Srl, Milan, Italy) in independent 50 mL Falcon conical tubes (Corning Inc., NY, USA) 50 mL plastic tubes (121 °C and 100 kPa for 20 min), named TBH (Treated Bran Hemp), and then used as substrate for bacterial fermentations, named FBH (Fermented Bran Hemp). Before fermentation addition of the bacterial inoculum, the suspension was adjusted to 27 mL of volume, in order to add later just 3 mL of bacterial inoculum. Controls used were: i) not inoculated sterile HPB/water suspension (NF = Not Fermented); ii) not sterilized nor inoculated sample (BH = Bran Hemp); iii) and a commercial hemp seed flour (HF) (Hanf & Natur, Lindlar, Germany) in a similar water suspension.

### 2.2. Microbial strains and culture conditions

All microbial strains tested belong to the microbial collection of DISTAL (Dept. of Agricultural and Food Sciences), University of Bologna (Bologna, Italy) and have been previously isolated from plant-based products and extensively studied (Babini, Tagliazucchi, Martini, Dei Più & Gianotti, 2017; Nissen, Demircan, Taneyo-Saa & Gianotti, 2019; Babini, et al. 2020; Nissen, di Carlo & Gianotti, 2020; Nissen, Casciano & Gianotti, 2021). *Lactiplantibacillus plantarum* subsp. *plantarum* 98b, *Limosilactobacillus fermentum* MR13, *Lacticaseibacillus rhamnosus* C1112 (used for hemp bran fermentation), *Bifidobacterium bifidum* NCIMB 700795 and *Escherichia coli* ATCC 25922 (used for prebiotic activity) were cultured from glycerol stocks stored at -80 °C and were propagated in selective media (Oxoid, Thermo Fisher Scientific, Waltham, MA, USA) at specific conditions (Nissen, di Carlo & Gianotti, 2020).

162

### 2.3. Fermentations

The hemp seed bran samples were fermented independently by *Lc. rhamnosus* C1112 (C), *Lp. plantarum* 98b (L), *Lm. fermentum* MR13 (M), and by a bacterial pool (P) containing equal proportion of the aforementioned strains. Cell load of inoculated bacteria was standardized by spectrophotometric means based on plate counts and qPCR (quantitative PCR). ~~I. For each~~ ~~inoculum were made by three~~ 3 mL of 7 Log<sub>10</sub> cells/mL of bacterial cells, ~~were~~ centrifuged and resuspend two times in sterile distilled water. ~~Each inoculum was added to 27 mL of TBH~~ ~~besuspension fore addition to TBH, whose fermentation was conducted in 30 mL. Fermentation and~~ ~~fermentation~~ was conducted aerobically at 37 °C up to 72 h in 50 mL Falcon conical tubes (Corning, USA) aerobically at 37 °C up to 72 h to obtain FBH (Fermented HB) samples. Each duplicate of a time point sample was made in distinct 50 mL Falcon conical tubes (Corning, USA). Non inoculated autoclaved hemp bran (TBH) was used as control. Two biological replicates of each sample were performed. For each inoculated sample (C, L, M, and P) sampling was performed after 6, 24, 48, and 72 h as reported in Supplementary Table 1. Analyses were regarded to bacterial quantifications, pH, and VOCs (volatile organic compounds) characterization at least in duplicates.

178

179 **2.4. Bacterial CFU-Culture-Dependent Counting**

180 For all bacteria 1 mL of each sample was aseptically transferred into a sterile tube ~~of~~ with 9 mL of  
181 physiological solution (0.9 g/dL NaCl) to be serially diluted (1/10) and plated in  
182 duplicates. Lactobacilli and the pool were counted on MRS agar (Oxoid, Thermo Fisher Scientific,  
183 USA) after incubation for at least 24 h at 37 °C in jars with anaerobiosis catalyst (Oxoid, Thermo  
184 Fischer Scientific, USA). *B. bifidum* NCIMB 700795 was counted on MRS agar supplemented with  
185 0.005 g/dL L-cysteine (Sigma, USA) after incubation in the same conditions of lactobacilli. *E.*  
186 *coli* ATCC 25922 was counted on BHI agar (Oxoid, Thermo Fisher Scientific, USA) at 37 °C for  
187 24 h.

188

189 **2.5. pH measurement**

190 The pH was determined with a pH-meter (Crison, Alella, Spain) at 20 °C appropriately calibrated  
191 with three standard buffer solutions at pH 9.21, pH 4.00, and pH 2.00. The pH values were  
192 measured in duplicate at three different times to monitor the fermentation.

193

194 **2.6. Quantification by qPCR**

195 Bacterial DNA from fermented hemp bran and from broths for prebiotic activity assay was  
196 extracted with the Pure Link Microbiome kit (Invitrogen, Thermo Fisher Scientific, USA). Genetic  
197 standards for qPCR were prepared from serially diluted PCR products (1/10) obtained amplifying  
198 gene targets with specific primers (Supplementary Table 2) with ProFlex PCR System (Thermo  
199 Fisher Scientific, USA) and SuperFi Platinum Taq (Thermo Fisher Scientific, USA), and purified  
200 with GeneJet PCR purification kit (Thermo Fisher Scientific, USA). qPCR was performed with a  
201 RotorGene 6000 (Qiagen, Hilden, Germany) and the RotorGene Q Series Software 2.3.1 (Qiagen,  
202 Germany). PCR and qPCR reactions were performed according to previously published protocols

(Nissen, Demircan, Taneyo-Saa & Gianotti, 2019; Nissen, di Carlo & Gianotti, 2020; Nissen, Bordini & Gianotti, 2020).

## 2.7. Prebiotic activity

The best performing time point, selected based on the best growth and pH reduction, was used to choose the FBH samples to screen for prebiotic activity, that was calculated with the related formula from two independent experiments and triplicates as previously described (Fissore, Santo Domingo, Gerschenson & Giannuzzi, 2015; Huebner, Wehling, Parkhurst & Hutkins, 2008), including qPCR quantifications (Nissen, di Carlo & Gianotti, 2020). FBH samples were filtered (Minisart® Syringe Filter 0.22 µm, Sartorius, Gottingen, Germany) and then all samples including BH and TBH controls were freeze dried using a Savant freeze-dryer Lyolab 3000 apparatus (Thermo Fisher Scientific, USA), in order to add a 1g/dL of product to 10 mL of culture media. FOS from chicory (Sigma, USA) was used as prebiotic positive control, and FH (commercial hemp seed flour) sample ~~was used as an additional control, along with prebiotic positive control fructo-~~ oligosaccharides (FOS) from chicory (Sigma, USA). The media employed as control to calculate the prebiotic scores were instead added with 1g/dL of glucose. The bacterial type strains Lp. plantarum ~~Lb. plantarum~~ 98b, *B. bifidum* NCIMB 700795, and *E. coli* ATCC 25922 were used at final concentration of 6 Log<sub>10</sub> CFU/mL (Fissore, Santo Domingo, Gerschenson & Giannuzzi, 2015; Nissen, di Carlo & Gianotti, 2020).

## 2.8. Solid-Phase Microextraction Gas chromatography/Mass spectrometry (SPME-GC-MS)

Evaluation of VOCs was carried out on an Agilent 7890A Gas Chromatograph (Agilent Technologies, Santa Clara, CA, USA) coupled to an Agilent Technologies 5975 mass spectrometer operating in the electron impact mode (ionization voltage of 70 eV), equipped with a Chrompack CP-Wax 52 CB capillary column (50 m length, 0.32 mm ID) (Chrompack, Middelburg, NL). The protocols for SPME-GC-MS analyses and for the identification of VOCs were previously published

(Guerzoni, Vernocchi, Ndagijimana, Gianotti & Lanciotti, 2007; Di Cagno et al., 2011; Nissen, Demircan, Taneyo-Saa & Gianotti, 2019; ~~Nissen, di Carlo & Gianotti, 2020~~; Nissen, ~~Caseiano-di Carlo & Gianotti, 2020~~). Briefly, before each SPME sampling, the fiber was exposed to the GC inlet for 10 min for thermal desorption at 250 °C in a blank sample. Prior analyses 6 µL of 10,000 mg/mk of 2-Pentanol, 4-methyl (Merck, Darmstadt, Germany) as internal standard were injected into the vial containing 3 mL of liquid sample and let to equilibrate for 10 min at 40 °C in a water bath. The SPME fiber was exposed to each sample for 40 min, and finally the fiber was inserted into the injection port of the GC for a 10 min sample desorption. The temperature program was: 50 °C for 1 min, then programmed at 1.5 °C/min to 65 °C, and finally at 3.5 °C/min to 220 °C, which was maintained for 25 min. Injector, interface, and ion source temperatures were 250, 250, and 230 °C, respectively. Injections were carried out in split-less mode and helium (3 mL/min) was used as a carrier gas. Identification was obtained with NIST 11 MSMS library and the NIST MS Search program 2.0 (NIST, Gaithersburg, MD, USA). Acetic acid, Propionic acid, and Butyric acid were absolutely quantified in mg/kg ~~employing an internal standard~~ (Di Cagno et al., 2011; Nissen, di Carlo & Gianotti, 2020) (LOQ = 0.03 mg/kg and LOD = 0.01 mg/kg), while terpenes compounds were relatively quantified from chromatogram peak areas, as a ratio peak area/total peak of different samples (Bonfrate et al, 2020) (LOD = 0.001 mg/kg) and then normalized with the mean centering method (~~Nissen, Demircan, Taneyo-Saa & Gianotti, 2019; Nissen, di Carlo & Gianotti, 2020; Nissen, Caseiano-Bordoni & Gianotti, 2020~~). The samples analyzed were 3 mL of each time points case, namely 0 h, 6 h, 24 h, 48 h, and 72 h. The Samples analyzed were those collected from two technical replicas of two independent experiments.

## 2.9. Statistical analyses

All statistical analyses were performed using TIBCO Statistica 8.0 (Tibco Inc., Palo Alto, CA, USA). Normality was checked with the Shapiro-Wilk's test and homoscedasticity was evaluated with the Levene's test (Granato, Araujo Calado & Jarvis, 2015). Differences between all samples

were evaluated with Analysis of Variance (ANOVA), while Principal Component Analysis (PCA), K-Means clustering, Spearman Rank Correlations, Two-way joining heatmap, and MANOVA were used to study the relationship between the variables (Nissen et al., 2020). To compare a sample to another within the same dependent variables a Student's T-test was employed ( $P < 0.05$ ), while to compare different cases and different variables was used a Tukey's HSD (Honestly Significant Differences) test ( $P < 0.05$ ). For PCA and Spearman Rank Correlations, the dataset was normalized using the mean centering method, including terpenes VOCs, delta pH, delta values of bacterial growth, and the prebiotic scores. All results are expressed as mean values obtained at least from duplicates batches in two independent experiments. qPCR and pH results were obtained from three replicates from two independent experiments.

265

### 3. Results

#### 3.1. pH values, bacterial quantifications of TBH fermentations

pH values were expressed as delta reduction over time (Supplementary Table 3). ~~Starting from The initial pH of every sample had a~~ mean ~~pH~~ value of  $6.55 \pm 0.06$ , ~~then~~ acidification was induced ~~actively lasting~~ up to 24 h or 48 h and a plateau was maintained afterwards. ~~After~~ Indeed, after 24 h, the mean pH reduction was  $2.16 \pm 0.19$  ( $P < 0.05$ ) ~~but and~~ no significant differences were seen up to the endpoint (72 h) ( $P < 0.05$ ). C1112 (C) was the ~~best and fastest in the acidification of the medium, scoring the top value among the dataset at the early time point~~ sample that after 24 h generated the maximum reduction of pH ( $-2.38 \pm 0.17$ ). Bacterial quantifications were expressed as means values of plate counts and qPCR results, and they were presented as cell number increase, expressed as  $\text{Log}_{10}$  cells/mL (Supplementary Table 4). Generally, in TBH samples all inocula kept growing exponentially up to 48 h ( $5.96 \pm 0.31 \text{ Log}_{10} \text{ cells/mL}$ ) ( $P < 0.05$ ). M13 (M) and the bacterial pool (P) were the most competitive inocula, being faster and more long-lasting, for example at the endpoint the increases were about  $6.35 \pm 0.28$  and  $6.66 \pm 0.35$ , respectively.

280

### 3.2. Volatile (low molecular weight) organic acids

Quantifications of volatile ~~acetic~~Acetic, ~~propionic~~Propionic, and ~~butyric~~Butyric acids ~~are~~ reported in mg/kg, and ~~the mean values of any each mean value of Ffermented HPBH samples were~~ ~~was~~ compared to ~~that of~~ NF samples. In Figure 1A and Supplementary Table 5 ~~it is described that~~ the abundance of ~~acetic~~Acetic acid increased on a time-basis. In ~~fact~~details, ~~it this organic acid~~ was found in traces (lower than 0.5 mg/kg) in NF cases but ~~after~~fermentation of TBH by any bacterial inoculum was able to increase~~accounted for significantly higher means values the content~~ ( $P < 0.05$ ). ~~Samples C, M, and L (LB325) were able to~~ ~~Theincrease the trend of every sample~~ ~~fermented~~quantity of Acetic acid exponentially during fermentation up to the endpoint, while P ~~with single inoculum was defined by an exponential raise up to~~ ~~was able up to~~ 48 hours and followed by a lighter one up to the endpoint. ~~Differently acted the pool of strains whose curve~~ ~~reached earlier a higher top value and declined afterwards.~~ The maximum mean value ~~amid among~~ the dataset was that of P48, accounting for  $11.13 \pm 1.01$  mg/kg, the double more than the mean of every single inoculum at that timepoint ( $P < 0.05$ ). Considering the single ~~inocula~~inoculum, the best doer was ~~CLb. rhamnosus C1112~~ at 72 h (C72), recording  $7.43 \pm 0.72$  mg/kg. The high levels of ~~acetate~~Acetic acid recorded by P48 were consistent with high bacterial growth, but not with mild acidification observed.

In Figure 1B and Supplementary Table 5 the mean values of ~~propionic~~Propionic acid are described. ~~TFor this compound , a similar scenario to acetic acid was seen. In fact, ffrom a very low-little value~~ in NF ( $0.04 \pm 0.04$  mg/kg) ~~, the production of propionic acid was raisingraised~~ constantly over time up to the endpoint for ~~the average of single inoculum~~C, L, and M, and up to 48 h for ~~the pool~~P. ~~Considering the mean of values of C, L, and M, Propionic acid abundance was 5.75-, 10.58-, and 14.25-folds larger at 24, 48, and 72 h. Excluding not significant early time point increase ( $P > 0.05$ ), the increment means of the single inocula were 5.75 , 10.58 , and 14.25-folds more at 24, 48, and 72 h, respectively.~~ Otherwise, the increment values performed by ~~the pool~~P were 24.00-, 29.00-, and 22.00-folds more at 24, 48, and 72 h, respectively. Thus, ~~the pool~~P already produced higher

yields at 24 h, 4.17-folds more than ~~the average of single inocula~~ the mean of C, L, and M. The  
 maximum value among the dataset was once more that of P48, scoring  $1.16 \pm 0.13$  mg/kg, 2.74-  
 folds more than the mean of every single inoculum at that timepoint ( $P < 0.05$ ). Considering ~~the~~  
 single ~~inocula~~inoculum, the best performer was ~~MLb. fermentum MR13~~ at 72 -h (M72), recording  
 $0.71 \pm 0.15$  mg/kg.

Butyric acid quantification (Figure 1C and Supplementary Table 5) showed significant differences  
 when ~~fermented cases FBH samples~~ were compared to NF ~~mean values~~samples ( $P < 0.05$ ), ~~except~~  
~~for those at the early time point. In fact, f~~From a very low value in NF ( $0.08 \pm 0.02$  mg/kg), ~~all~~  
~~single inoculum samples~~C, L, and M produced constant higher yields up to the endpoint, while ~~the~~  
~~pool~~P reached the top value at 48 h and declined slightly after. Excluding not significant early time  
 point increase ( $P > 0.05$ ), the increment means of ~~the single inocula~~C, L, and M were 5.00-, 11.58-,  
 and 17.00-folds more at 24, 48, and 72 h, respectively. Otherwise the increases performed by ~~the~~  
~~pool~~P were 15.10-, 26.00-, and 20.08-folds more at 24, 48, and 72 h, respectively. Thus, ~~the pool~~P  
 already produced higher yields at 24-h, 5.00-folds more than the ~~average mean~~ of single C, L, and  
 M ~~single inocula~~. The maximum value among the dataset was once more that of P48, scoring  $2.08$   
 $\pm 0.17$  mg/kg, 2.24-folds more than the mean of every inoculum at that timepoint ( $P < 0.05$ ).  
 Considering the single inocula~~s~~, the best producer was ~~CLb. rhammosus C1112~~ at 72 h (C72),  
 recording  $1.53 \pm 0.14$  mg/kg.

In summary, TBH samples fermented with the bacterial pool ~~accounted for~~recorded the highest  
~~yields values~~ of the three organic acids, ~~and the time of fermentation that gave overall the best~~  
~~performances was set, principally~~ at 48 h.

### 3.3. Terpenes

Among the whole dataset of identified VOCs, we selected 37 compounds, based on their chemical  
 class (terpenes and sesquiterpenes), normality distribution, significant difference of variance ( $P <$   
 $0.05$ ), and ~~new~~proved~~n~~ bioactivity (Figure 2). From the PCAs (Figures ~~4A-2A~~ and ~~2B~~) a robust

plane was evidenced, based on two factors defining the 26.11% and 26.63% of total representations.

Coupling PCAs to K-Means clustering analysis (Figure ~~4C~~2C) it was possible to identify five clusters of ~~samples-cases~~ described by significant differences ( $P < 0.05$ ) on ~~relative abundances of~~ 30 molecules. In Figure 2A, cluster 1 (~~blue dot~~) was positioned on quadrant III of PCA's plane oriented distant to the left side and grouped just NF samples. This cluster was described by 30 compounds but just eight had relative higher ( ~~$P < 0.05$~~ ) abundances ( $P < 0.05$ ) than FBH samples, such as  ~~$\beta$ -pinene~~Pinene,  $\gamma$ -Elemene, cis- $\beta$ -Farnesene, Aromadendrene, 9-methyldecalinMethyldecalin,  $\alpha$ -Farnesene, Geraniol, and Myrtenal. Thereof, all other ~~samples-cases~~ ( $n = 32$ ) were ~~relative to the FBH ones~~ samples and were distributed in four specific clusters.

Cluster 2 (~~fuchsia dot~~) included ~~early time pointall the samplecases at the early time points plus two relatives to 24 h time pointand other two~~ (L24 and L24\_2) ~~and was mainly fitted in quadrant IV of PCA's plane~~. This cluster was described by 17 variables, but just three ~~had abundancies relatively higherwere more abundant~~ than ~~those found in~~ other clusters ( $P < 0.05$ ), i.e. ~~butylated~~ Butylated hydroxytoluene, trans-Pinocarveol, and *p*-Vinylguaicol. Cluster 3 included ~~just MR13 and LB325 fermented samples~~FBH samples fermented by M and L at intermediate and end time points. ~~In particular, M13 at 24, 48, and 72 h time points, while LB325 at 48 and 72 h time points. It~~ was described by 24 compounds, but none ~~had abundancieswas~~ significantly higher than ~~those of~~ other clusters ( $P > 0.05$ ). Cluster 4 included all ~~FBH samples the pool (P)~~ fermented by P samples except that at the early time point ~~and it was set in quadrant I of PCA's plane oriented to the top~~. It was described by 24 compounds, ~~whose-and~~ eight ~~had abundanciewere s~~ significantly ~~higher-more~~ abundant ( $P < 0.05$ ) than those of other clusters, i.e. Caryophyllene oxide, 1-(R)- $\alpha$ -Pinene, Eudesma-4(14),11-diene, *p*-Cymene, Myrcene,  $\Delta$ -3-Carene, 1-Octen-3-ol, and Citronellol. Cluster 5 contained ~~all the cases related to intermediate and end time point FBH samples fermented by C1112 fermented samples relatives to intermediate and end time points and was positioned in quadrant IV of PCA's plane~~. It was described by 23 terpenes ~~in varying abundancies, among whichand in particular~~ that of 4-Trimethylsilyl-9,9-dimethyl-9-silafluorene, 4(10)-Thujen-3-ol, acetate, and

Borneol were significantly more abundant significantly higher ( $P < 0.05$ ) than those of other clusters ( $P < 0.05$ ). In summary, the products of TBH fermentation that had the largest speciation and the highest yield abundance of in terpenes were that those obtained relatively to TBH samples fermented by the pool and by P and C-1112 at least after 48 h of incubation.

### 3.4. Targeted MANOVA: fermentation dynamics and strain performances

MANOVA ( $P < 0.01$ ) was performed. The on the dataset of the 37 normally distributed variables with two categorical predictors: i) was categorized on the bacterial inoculum and ii) on the time of fermentation to perform MANOVA ( $P < 0.01$ ) (Figure 3A and B Tables 1 and 2), in order to address specifically the production of terpenes. Considering the different fermenting agent bacterial inoculum (Figure 3A Table 1), 20 variables had significant differences ( $P < 0.01$ ) and it emerged that not fermented samples NF (Control) samples were the sole account described by Geraniol (100%), and for more than the 76.0% of total 9-Methyldecalin (76.0%), and 72.1% of  $\beta$ -Selinene (72.1%) abundances. The quantities of the remaining 17 VOCs were all significantly augmented with fermentation. In particular, some compounds were produced in higher proportion by a given inoculum in respect to the others, and differently by the inoculum. For example, C-1112 was responsible for 48.9% of total production of  $\alpha$ -Caryophyllene, 40.6% of Borneol, and 43.2% of Eucalyptol. Fermentation by LB-325 led to the production of 52.9% of total  $\beta$ -Linalool and 37.7% of total *p*-Cymen-8-ol. Fermentation conducted by MR-13 was distinguished by 49.9% of total abundance of *p*-Cymene and by 50.5% of total Myrtenal. The pool P was responsible for the 59.9% of the total yield in 1-(R)- $\alpha$ -pinene Pinene, for the 63.9% of total  $\gamma$ -Elemene, the 57.6% of total cis- $\beta$ -Farnesene, the 51.8% of total Myrcene, the 44.8% of total  $\Delta$ -3-carene Carene, the 47.8% of total Fenchyl alcohol, the 45.8% of total 4(10)-Thujen-3-ol, acetate, and the 45.8% of total Eugenol. So far, TBH fermented by the pool showed to be the inoculum that accounted for higher production of more compounds than the single strains. In fact, the pool P produced had higher amount of 9 terpenes in comparison to the 3 of C-1112, and the 2 of both LB-325 and MR-13.

Instead, considering the MANOVA categorized for the time points of fermentation showed that, 20 compounds VOCs had significant differences among the independent variables ( $P < 0.01$ ) (Figure Table 234). Seven terpenes were intrinsic features of HPB and were not subject to significant increases through with fermentation, in particular:  $\beta$ -Pinene, and Geraniol, and  $\alpha$ -Farnesene were almost not detected after fermentation an exclusive signature of NF samples. The other compounds were: Aromadendrene, accounting for the 66.4% of total abundance, 9 Methyldecalin, accounting for the 76.0%,  $\beta$ -Selinene for the 72.1%, and  $\alpha$ -Farnesene for the 94.6%. For any other compound, the abundance was in higher proportion at the late time points. In fact In brief, after 24 h just the 33.7% of total Eucalyptol and the 62.6% of total p-Vinylguaiacol were produced. Instead, after at 48 h the VOCs discriminated were: 70.9% of total Eudesma-4(14), 11-diene, (70.9%), as well as the 50.9% of total p-Cymene (50.9%), the 56.6% of total Terpinolene (56.6%), the 40.6% of total 1-Octen-3-ol (40.6%), and the 42.1% of total 2-Decen-1-ol, (E) (42.1%) were produced. Lastly, at the end point major proportions on total yields of  $\gamma$ -Elemene (84.4%), of Citronellol (38.6%), and of Myrtenal (54.4%) were achieved.

### 3.5. Prebiotic score

The prebiotic scores were calculated from the equation proposed by Huebner, Wehling & Hutkins, (2007) and revised by Fissore, Santo Domingo, Gerschenson & Giannuzzi, (2015), which considers the effect of a fiber in comparison to glucose towards the growth of a beneficial bacteria in respect to the growth of pathogenic *E. coli*. The highest score for prebiotic activity (Table 43) versus *Lp. plantarum* *Lb. plantarum* 98b was achieved by P48, that was the sole sample scoring significantly higher than FOS ( $P < 0.05$ ). In fact particular, TBH fermented by P48 was significantly stronger than FOS in the containment of *E. coli* ATCC 25922 even if the growth of *Lb. plantarum* 98b on 1 g/dL of TBH fermented by P48 was slightly lower than that of FOS, the inhibition of the former on *E. coli* ATCC 25922 was significantly stronger ( $P < 0.05$ ) (Supplementary Table 6). Besides, in comparison to FH, TBH fermented by P48 P48 reached a prebiotic score on had a prebiotic score

1.8-folds higher versus *Lp. plantarum* 98b. *Lb. plantarum* 98b 1.8 folds higher than FH that had the lowest value. The prebiotic score raised in respect to score raised in respect to the intensity of HPB treatment, in details BH had the lowest value and TBH the highest from the lowest of BH to the top of fermented TBH. Among the fermented samples the runner up was C48, with a score slightly lower than FOS, but significantly higher than similar samples (L48 and M48). Considering the prebiotic activity towards *B. bifidum* NCIMB 700795 (Table 43), a similar trend was evidenced. The best performing sample was C48, higher than FOS and P48, but with no significant difference ( $P > 0.05$ ). Even in this context, Similarly to the previous prebiotic target, FOS made foster more *B. bifidum* NCIMB 700795 to grow more than the best TBH fermented sample (C48), but this latter was stronger in the containment of *E. coli* ATCC 25922 inhibition ( $P < 0.05$ ) (Supplementary Table 6). Besides, TBH fermented by C48 hit the top prebiotic score versus *B. bifidum* NCIMB 700795 and was significantly different from any other samples ( $P < 0.05$ ) was seen in respect to all other samples, and in particular the prebiotic activity of C48 was 1.7 folds more effective than that of FH. Thus, both C48 and then P48 scored higher values than other fermented or not fermented samples ( $P < 0.05$ ). In brief, among the strains tested after 48 h of fermentation of the pool TBH, the pool demonstrated to produce a substrate that had the top with the best prebiotic activity versus lactobacilli *Lp. plantarum*, while C48 hit the top with the best versus *B. bifidum* bifidobacteria.

### 3.6. Spearman rank correlations

We used Spearman rank analysis to evidence correlations between variables related to ecological features (bacterial growth, pH decrease, and prebiotic activity) and those related to abundances of VOCs considered, on independent variables ( $n = 32$ ) (Figure 43). Considering the bacterial growth, The variable "delta cells" indicates the was obtained from the difference of  $\log_{10}$  cells/mL at the endpoint and between the beginning and end of fermentation. Significant correlations ( $P < 0.05$ ) indicated evidenced that during fermentation of TBH samples the the more growth of bacterial grew in fermentation the more was positively correlated with quantity of SCFAs and minorly p-

437 Cymene, and Citronellol ~~was found in fermented TBH samples~~. In contrast three terpenes, *i.e.*  
 438 Caryophyllene,  $\Delta$ -3-Carene, and  $\beta$ -Selinene, were inversely ~~proportional-correlated~~ to bacterial  
 439 growth. ~~It is likely that their accumulation in the substrate resulted in a constraint for lactobacilli.~~  
 440 ~~As a matter of fact, Considering that from previous MANOVA ( $P < 0.05$ ) resulted that the longer~~  
 441 ~~was the fermentation time the larger the quantity of these three VOCs from MANOVA was found~~  
 442 ~~that almost 50% of total yield of these VOCs was fostered by fermentation, it is likely that their~~  
 443 ~~accumulation in the substrate resulted in a constraint for lactobacilli as the fermentation was~~  
 444 ~~prolonged over time when bacterial load was richer.~~  
 445 ~~Acetic acid abundance was even significantly proportional to acidification, as well as that of 1-~~  
 446 ~~Octen-3-ol and Fenchyl alcohol.~~ Considering the prebiotic activity, it is interest to stress out that  
 447 correlation trend was similar for both probiotics. A group of ~~terpenes-VOCs~~ including *p*-Cymene,  
 448 Myrcene, Eugenol, 1-Octen-3-ol, Terpinolene, and  $\beta$ -Pinene resulted significantly associated to  
 449 prebiotic activity ( $P < 0.05$ ), while Caryophyllene, Eucalyptol, and  $\beta$ -~~linalool-Linalool~~ were  
 450 ~~negative~~~~inversely proportional-correlated~~ ( $P < 0.05$ ). This issue could mean that ~~just the former list~~  
 451 ~~of VOCs related to prebiotic activity has generate a selective bioactivity versus certain~~  
 452 ~~baeteriaeffects, e.g. inhibiting-inhibition of enteropathogenic E. coli enteropathogens and capacity~~  
 453 ~~to fostering probiotics-B. bifidum or lactobacilli Lp. plantarum, instead the latter list of VOCs had a~~  
 454 ~~broader spectrum of antimicrobial activity.~~

455

#### 456 4. Discussion

457 ~~When TBH was fermented, interestingly-Interestingly, when TBH was fermented~~ the high  
 458 lactobacilli ~~load~~~~growth~~, and the high content of ~~aeetic-Acetic~~ acid did not lead to extreme  
 459 acidification levels. In fact, the pH values were not reduced excessively (C1112 hit top acidification  
 460 after 48 h with pH value of  $4.21 \pm 0.02$ ), ~~likely-like~~ happens ~~during the most of fermentation~~  
 461 ~~processes performed on when~~ plant-based material ~~are fermented~~. For example, lactobacilli  
 462 fermenting carrot, cabbage or radish can bring pH down to less than 4 after 72 h (Vatansever, Vegi,

Garden-Robinson & Hall, 2017). Kimchi fermentation by indigenous LAB, ~~including *Laetobacillus*~~  
~~spp.~~, can acidify the substrate up to pH 3.5 after 24 h (Joon-Yeon & Kunz, 2009). In our work, from  
24 h to the ~~endtime~~ point the pH ~~remained was~~ stable with a mean ~~value~~ of  $4.41 \pm 0.15$ , ~~besides and~~  
~~in this period~~ bacterial cells kept growing up to ~~an endpoint~~ a mean of  $12.23 \pm 0.24 \text{ Log}_{10} \text{ cells/mL}$ .  
Therefore, HPB positively ~~reflects the essential~~ showed characteristic of to be a substrate ~~for which~~  
fosters probiotic growth ~~including and owns~~ a pH buffering capacity (Nissen, di Carlo & Gianotti,  
2020).

The prebiotic activity ~~scored recorded~~ by fermented TBH was surprisingly effective even due to a  
stronger containment of the growth of *E. coli* ATCC 25922, in comparison to other samples and the  
FOS. Hemp female inflorescences and hemp seeds bring many terpenes with renowned  
antimicrobial activity ~~(Nissen et al., 2010; Pellati, Brighenti, Sperlea, Marchetti, Bertelli &~~  
~~Benvenuti et al., 2018; Leghissa, Hildenbrand & Schug, 2018)~~, that alone or in synergism show to  
be capable to inhibit opportunistic and food borne pathogens (Nuutinen, 2018; Nafis et al., 2019).  
~~The antimicrobial activity of hemp seed is reckoned to be triggered by the synergistic effects of~~  
~~different terpenes present in hemp seed oil (Nafis et al., 2019; Nissen et al., 2010).~~ On the  
contrary, other plant-based materials able to foster probiotics do not have a prebiotic activity  
because cannot tackle the growth of enteropathogens (Vieira, Bedani, Albuquerque, Biscola &  
Saad, 2017). A fundamental criterium to classify a food ingredient as a prebiotic is the scientific  
ability to foster the growth and support the activity of beneficial intestinal bacteria (Gibson et al.  
2017). In this view the assay of prebiotic activity adopted reflects the ability of a prebiotic to  
~~jointly mutually~~ foster the growth of probiotics and limit that of enteropathogens in comparison to  
glucose (Fissore, Santo Domingo, Gerschenson & Giannuzzi, 2015; Huebner, Wehling, Parkhurst  
& Hutkins, 2008). Another element that supports the ~~The s~~ strong prebiotic activity of FBH that we  
have observed could be ~~partly due to the recorded~~ higher ~~quantity levels~~ of ~~acetic~~ Acetic,  
propionic Propionic, and butyric Butyric acids generated s, particularly by fermentation with in P48  
and ~~in~~ C72. Lactobacilli are able to liberate and produce low organic acids during fibers

degradation, thus improving the original content in the fermented product (Massa et al., 2020). The quality and quantity of these organic acids depend on the type of fiber used (Gill, van Zelm, Muir & Gibson 2018).

In fact, the beneficial effects of low organic acids are renowned and are multi-targets, not solely directed to the host epithelial mucosa, and to the blood stream, but even to the microbiota, as a selective substrate (Goverse et al., 2017). A abundant production of these compounds is linked to well-being (Goverse et al., 2017) and their nutritional supplementation are-is suggested for the treatment of in-different intestinal diseases (Gill, van Zelm, Muir & Gibson 2018).

From Spearman Rank correlation, the abundance of *p*-Cymene, Myrcene, Eugenol, 1-Octen-3-ol, Terpinolene, and  $\beta$ -Pinene was linked to prebiotic activity, and all these VOCs, except the latter, were increased with fermentation of TBH. These results are in line with recent literature, where it is reported that bacterial fermentation is able to improve the original terpenes content of cheese (Alves Bezerra et al., 2017), mango peel (Jin et al., 2018), okara from soybean (Gupta, Lee & Chen, 2018), hemp seed drinks (Nissen, di Carlo & Gianotti, 2020), hemp seed enriched doughs (Nissen, Bordoni, Gianotti, 2020), and blueberry pomace (Cheng et al., 2020). The antimicrobial properties and the applications in foods of terpenes such as *p*-Cymene (Marchese et al., 2017), Terpinolene (Fiorini et al., 2019; Karas et al., 2020), Myrcene (Mitropoulou et al., 2107), and Eugenol (Talón, Vargas, Chiralt & González-Martínez, 2019) is proved. Additionally, these VOCs are promising health related compounds due to the strong anti-oxidant and anti-inflammatory capacity, as good radicals' scavengers (De Oliveira et al., 2015; Boulebd, 2021; Yi, Sun, Bao, Ma & Sun, 2019; da Silva et al., 2018). Myrcene that was plenty in FBH samples. In fact, this monoterpene rules almost a third of Futura 75 hemp seed essential oil content (Nissen et al., 2010), and besides has antioxidant and anti-inflammatory capacities (Mitropoulou et al., 2107; Yi, Sun, Bao, Ma & Sun, 2019). Then we found high abundance of Terpinolene, that is a monoterpene and a structural isomer of (+) Limonene that is found largely in hemp inflorescence up to 9.7% of total weight, and is currently used in the food industry (Fiorini, Molle, Nabissi, Santini, Benelli & Maggi, 2019). It has

515 been reported to have antioxidant capacities as a good radicals' scavengers (Boulebd, 2021), and to  
 516 act as antimicrobial (Karas, Wong, Paulin, Mazeh, Hussein, Li & Velkov, 2020). Eugenol is a  
 517 natural phenolic compound found abundantly in cinnamon and in clove essential oils and is the  
 518 main responsible for clove aroma (Talón, Vargas, Chiralt & González-Martínez, 2019). Eugenol is  
 519 indicated for several therapeutic effects, because is a good radicals' scavengers with antibacterial  
 520 effect (da Silva, Monte, de Lemos, do Nascimento, Costa, de Paiva, 2018). *p*-Cymene is a  
 521 monoterpene found in more than 100 plant species able to counteract different food borne  
 522 pathogens (Marchese et al., 2017). It shows numerous biological activities, increasing the activity of  
 523 antioxidant enzymes, contributing to reduce oxidative stress (De Oliveira et al., 2015).  
 524 ~~Thus, according to the new definition of prebiotics, FBH had an higher prebiotic score than FOS~~  
 525 ~~because its effect was jointly generated by other beneficial compounds and the polysaccharides. In~~  
 526 ~~fact, considering metabolomics, multivariate analysis defined that HPB samples prior fermentation~~  
 527 ~~were described by 28 different terpenes, whose two were exclusively found at this stage, such as  $\beta$ -~~  
 528 ~~Pinene and Geraniol. The other compounds were all positively subjected to the effect of~~  
 529 ~~fermentation process, which have surged their release. Consequently, in our study the more the~~  
 530 ~~terpenes-bioactive VOCs (low organic acids and terpenes) were abundant and the more the prebiotic~~  
 531 ~~activity was effective. , microbial fermentation is able to improve the original terpenes content of~~  
 532 ~~cheese (Alves Bezerra et al., 2017), mango peel (Jin et al., 2018), okara from soybean (Gupta, Lee~~  
 533 ~~& Chen, 2018), hemp seed drinks, and hemp seed enriched doughs (Nissen, di Carlo, Gianotti,~~  
 534 ~~2020; Nissen, Bordoní, Gianotti, 2020), and blueberry pomace (Cheng et al., 2020). Actually, from~~  
 535 ~~Spearman-Rank correlation, the abundance of *p*-Cymene, Myrcene, Eugenol, 1-Octen-3-ol,~~  
 536 ~~Terpinolene, and  $\beta$ -Pinene was linked to prebiotic activity, and all these VOCs, except the latter,~~  
 537 ~~were increased throughout fermentation of TBH.~~  
 538 Thus, according to the new definition of prebiotics, FBH had a higher prebiotic score than FOS  
 539 because its effect was jointly generated by other beneficial compounds and the polysaccharides.

540 ~~Lactobacilli are able to liberate and produce low organic acids during fibers degradation, thus~~  
 541 ~~improving the original content in the fermented product (Massa et al., 2020). Besides the organic~~  
 542 ~~acids production is differently triggered by different fibers (Gill, van Zelm, Muir & Gibson 2018).~~  
 543 ~~Similarly, microbial fermentation is able to improve the original terpenes content of cheese (Alves~~  
 544 ~~Bezerra et al., 2017), mango peel (Jin et al., 2018), okara from soybean (Gupta, Lee & Chen, 2018),~~  
 545 ~~hemp seed drinks, and hemp seed enriched doughs (Nissen, di Carlo, Gianotti, 2020; Nissen,~~  
 546 ~~Bordoni, Gianotti, 2020), and blueberry pomace (Cheng et al., 2020).~~  
 547 ~~Hemp female inflorescences bring many terpenes (Nissen et al., 2010; Pellati, Brighenti, Sperlea,~~  
 548 ~~Marechetti, Bertelli & Benvenuti, 2018; Leghissa, Hildenbrand &~~  
 549 ~~Schug, 2018), that alone or in synergism show to be capable to inhibit food borne pathogens (Nafis~~  
 550 ~~et al., 2019).~~  
 551 ~~Among the most effective terpenes that we have detected and described there were five that recently~~  
 552 ~~attracted scientist for their biological activities, namely Myrcene, Terpinolene, Eugenol, p-Cymene,~~  
 553 ~~and l-Octen-3-ol. The first is Myrcene that was plenty in FBH samples. In fact, this monoterpene~~  
 554 ~~rules almost a third of Futura 75 hemp seed essential oil content (Nissen et al., 2010), and besides~~  
 555 ~~has antioxidant and anti-inflammatory capacities (Mitropoulou et al., 2107; Yi, Sun , Bao, Ma &~~  
 556 ~~Sun, 2019). Then we found high abundance of Terpinolene, that is a monoterpene and a structural~~  
 557 ~~isomer of (-) Limonene that is found largely in hemp inflorescence up to 9.7% of total weight, and~~  
 558 ~~is currently used in the food industry (Fiorini, Molle, Nabissi, Santini, Benelli & Maggi, 2019). It~~  
 559 ~~has been reported to have antioxidant capacities as a good radicals' scavengers (Boulebd, 2021),~~  
 560 ~~and to act as antimicrobial (Karas, Wong, Paulin, Mazeh, Hussein, Li & Velkov, 2020). Eugenol is~~  
 561 ~~a natural phenolic compound found abundantly in cinnamon and in clove essential oils and is the~~  
 562 ~~main responsible for clove aroma (Talón, Vargas, Chiralt & González-Martínez, 2019). Eugenol is~~  
 563 ~~indicated for several therapeutic effects, because is a good radicals' scavengers with antibacterial~~  
 564 ~~effect (da Silva, Monte, de Lemos, do Nascimento, Costa, de Paiva, 2018). p-Cymene is a~~  
 565 ~~monoterpene found in more than 100 plant species able to counteract different food borne~~

pathogens (Marchese et al., 2017). It shows numerous biological activities, increasing the activity of antioxidant enzymes, contributing to reduce oxidative stress (De Oliveira et al., 2015). 1-Octen-3-ol has been described in different plants and fungi and is a short-chain oxylipin, oxygenated derivative of linoleic acids, able to protect plants in response to external challenges (Zhang et al., 2021) and successfully tested *in vitro* against food-borne pathogens (Xiong, Li, Li, Chen, Chen, Huang, 2017). The bioactives that we have described use to act in synergism, resulting to exalt the beneficial effect for the host (Nafis et al., 2019; Nissen et al., 2010; Russo, 2011); for example, it has been proposed that phytocannabinoids and terpenoids interact together to deliver joint effect in the treatment of inflammation and microbial pathogenesis (Nuutinen, 2018). In this way a human colonic model may represent the proper *in vitro* approach for a deep knowledge of potential functionalities of HPB (Nissen, Casciano, Chiarello, Di Nunzio, Bordonì & Gianotti, 2021). Throughout the aid of such tools it will be possible to landscape the complexity of the shift of the microbial populations, as restraint of enteropathogens and promotion of probiotics, and to reveal in detail the metabolic fate of bioactive VOCs.

## 5. Conclusions

Development of functional foods for our next future could be afforded just employing sustainable approaches and renewable feedstock, including the exploitation of industrial byproducts. These needs could be satisfied by hemp seed that is a multi-tasking feedstock, is a powerhouse of nutrients and health related compounds. However its cultivation rinses the soil and gives generous yields with low-demanding attributes in terms of chemicals, land, and water. Also, the industrial process uses to discard potentially high value plant component, such as hemp seed bran HPB, that deserves to be valorized.

In the present work we have demonstrated that fermented hemp seed bran could be considered technically improved with fermentation, resulting in a product with higher prebiotic activity due

592 ~~to more is possible to extend to the byproducts the nutritional and health potential characters of the~~  
593 ~~principal feedstock, as well as to increase the original content and yields of certain~~ bioactives, such  
594 as SCFA-organic acids which fostered the growth of probiotics, and ~~some selected~~ terpenes that  
595 tackled enteropathogenic *E. coli*.

596 This work discovered that HPB is a fine substrate for beneficial lactobacilli, ~~as well as for~~  
597 ~~probiotics and propose to apply HPB as a prebiotic ingredient. Furthermore, for the first time,~~  
598 ~~unprocessed or differently treated and fermented HPB were assessed, compared, and discussed on~~  
599 ~~their prebiotic potential, targeting also the VOCs deputed to this bioactivity. Besides, with~~  
600 ~~fermentation of HPB the bioactives related to prebiotic activity could be increased. We have found~~  
601 ~~that the prebiotic activity of HPB samples is the result of the action of a pool of health-related~~  
602 ~~compounds, and that their presence is related to~~ production could be balanced by fermenta  
603 fermentation process ~~tion with specific bacteria. Considering the synergistic effort that different~~  
604 ~~terpenes generally use for the generation of the final bioactive effect, we can write that even the~~  
605 ~~prebiotic activity of HPB samples is the result of the action of a pool of health-related compounds.~~  
606 ~~The results were obtained by a robust multivariate statistical approach that permitted to discriminate~~  
607 ~~the contribution of each inoculum fermenting HPB on the prebiotic properties of the final product.~~  
608 Although this work is still an *in vitro* investigation, it  
609 ~~The present research~~ offers some statistically robust basics over the valorization of an outcasted  
610 byproduct derived from the industrial transformation chain of hemp seed foods ~~and the recipient~~  
611 ~~results vow that~~ and introduces that HPB could have prebiotic application.

#### 900 Figure captions

901 Figure 1. A) Acetic acid, B) Propionic acid, and C) Butyric acid quantification by SPME GC-MS of  
902 not fermented (NF) and fermented hemp bran (FBH), expressed in mg/kg. Plots are indicating  
903 results from two different replications and two independent experiments. Boxes indicate means  
904 values; rectangles indicate means values  $\pm$  S.D.; whiskers indicate means values  $\pm$  1.96\*S.D.

905 NF = not fermented TBH; C6, C24, C48, and C72 = TBH fermented by *Lactocaseibacillus*  
906 *rhannosus* C1112 after 6 h, 24 h, 48 h, and 72 h; L6, L24, L48, and L72 = TBH fermented by  
907 *Lactiplantibacillus plantarum subsp. plantarum* LB325 after 6 h, 24 h, 48 h, and 72 h; M6, M24,  
908 M48, and M72 = TBH fermented by *Limosilactobacillus fermentum* MR13 after 6 h, 24 h, 48 h, and  
909 72 h; P6, P24, P48, and P72 = TBH fermented by the pool after 6 h, 24 h, 48 h, and 72 h. Means  
910 with different letters are significantly different at  $P < 0.05$  by Student T-test.

911

912 Figure 2. Multivariate analysis on 37 VOCs terpenes quantified by SPME GC-MS of not fermented  
913 (NF) and fermented hemp bran (FBH) samples. (A) PCA of cases; (B) PCA of variables; (C) K-  
914 Means clusterization based on dependent variables. Cluster 1 = blue plot; Cluster 2 = fuchsia plot;  
915 Cluster 3 = green plot; Cluster 4 = black plot; Cluster 5 = yellow plot. \*1,4,7, Cycloundecatriene,  
916 1,5,9,9-tetramethyl-, Z,Z,Z-; \*\*4-Trimethylsilyl-9,9-dimethyl-9-silafluorene; \*\*\*Phenol, 2,4-bis(1,1-  
917 dimethylethyl)-. Codes of samples: X0 = not fermented samples; C6, C24, C48, and C72 = TBH  
918 fermented by *Lactocaseibacillus rhannosus* C1112 after 6 h, 24 h, 48 h, and 72 h; L6, L24, L48,  
919 and L72 = TBH fermented by *Lactiplantibacillus plantarum subsp. plantarum* LB325 after 6 h, 24  
920 h, 48 h, and 72 h; M6, M24, M48, and M72 = TBH fermented by *Limosilactobacillus fermentum*

921 MR13 after 6 h, 24 h, 48 h, and 72 h; P6, P24, P48, and P72 = TBH fermented by the pool after 6 h,  
922 24 h, 48 h, and 72 h.

923

924 ~~Figure 3. MANOVA plots of terpenes with categorical predictors ( $P < 0.01$ ) set on inocula (A) and~~  
925 ~~on time (B). \*\*\*Phenol, 2,4 bis(1,1 dimethylethyl) . % values indicate the contribution of each~~  
926 ~~categorized cases on the total load on the dataset of each dependent variable (the VOCs)~~

927

928 Figure 43. Two-way joining heatmap of double matrix Spearman rank correlations on VOCs  
929 terpenes of 32 independent variables from treated hemp bran (TBH), including not fermented TBH  
930 and TBH fermented (FBH) for 6 h, 24 h, 48 h, and 72h at 37 °C by *Lactocaseibacillus rhamnosus*  
931 C1112, *Lactiplantibacillus plantarum subsp. plantarum* LB325, *Limosilactobacillus fermentum*  
932 MR13, and by the pool of these three strains. \*  $P < 0.05$ . X Axis labels: Delta cells = Log cells/ml  
933 increase; [Delta pH] = Acidification of substrate; PS *Lb. plan* = Prebiotic Score on  
934 *Lactiplantibacillus plantarum subsp. plantarum* 98b; PS *B. bif* = Prebiotic Score on  
935 *Bifidobacterium bifidum* NCIMB 700795.
