**Abstract:** Over the centuries, strawberry fruit quality has greatly improved through various selection studies. The discovery of genes and genomic positions related to traits such as fruit quality and resistance to diseases and pests has been accelerated by new biotechnological methods. The objectives of this study are (i) to construct single nucleotide polymorphism (SNP) array-based high-throughput genetic linkage groups for the 'Fortuna × Rubygem' F<sub>1</sub> population, and (ii) to detect quantitative trait loci (QTL) regions associated with *Botrytis cinerea* resistance in leaf and fruit traits of strawberry. A total of 945 and 984 SNPs were mapped in the 'Fortuna' maternal and the 'Rubygem' paternal maps, respectively. The lengths of the linkage groups (LGs) and the average length of 'Fortuna' were calculated to be 1814 cM and 55.0 cM, respectively. The total length of 'Rubygem' was determined to be 2170 cM, with an average length of 65.7 cM. The average marker densities for the 'Fortuna' and 'Rubygem' linkages per cM were recorded as 0.58 and 0.53 markers, respectively. The 'Fortuna' female produced a mean of 28.64 markers per LG, while the 'Rubygem' male linkage groups had approximately 30 markers per LG. Five significant QTLs associated with resistance to *B. cinerea* in the leaves were identified in both parents. QTLs associated with resistance in strawberry fruits were found within a total of three LGs in different positions. The compressive genetic linkage maps developed in 'Fortuna × Rubygem' population can be used in genetic and QTL studies for important agronomical traits. The identified QTLs associated with *Botrytis cinerea* resistance may be preferred for use in future strawberry breeding programs to carry out marker-assisted selection.

**Key words:** Strawberry, *Botrytis cinerea*, quantitative trait loci (QTL), genetic mapping, *Fragaria × ananassa*

### 1. Introduction

Horticulture plants are highly diverse and have been recognized for their health benefits to humans. They contain a high concentration of nonnutritive, nutritive, and bioactive compounds, such as flavonoids, phenolics, anthocyanins, and phenolic acids, as well as nutritive compounds, such as sugars, essential oils, carotenoids, vitamins, and minerals. (Ercisli et al., 2010; Benjak et al., 2005; Celik et al., 2007; Erturk et al., 2012; Durul and Aktaş, 2023; Orman, 2023; Özkan, 2023; Wu et al., 2023).

Strawberry is one of the temperate climate fruit species with high adaptability and can be cultivated in

a wide ecological region from Ecuador to Siberia. It is one of 23 species in the Rosaceae family, which includes cherry, apple, and rose, and it belongs to the genus *Fragaria* (Shulaev et al., 2008). Commercially cultivated strawberries are octoploid (2n = 8x = 56), with a haploid chromosome number of n = 7 (Davis et al., 2007), and they constitute a significant portion of global production (Amil-Ruiz et al., 2011). The octoploid chromosomal scale reference genome of the Camarosa cultivar (*Fragaria × ananassa* Duchesne) has been released, with an estimated genome size of 813.4 Mb (Edger et al., 2019).

Strawberries are among the most important and highly nutritious fruits for human health due to their high

\* Correspondence: ebruyasakafkas@gmail.com

content of vitamin C, minerals, folates, and antioxidants (Giampieri et al., 2014). Several studies have indicated that consuming strawberries offers numerous health benefits, such as preventing aging, Alzheimer's disease, obesity, and various heart and cancer-related diseases (Zhang et al., 2008; Silva et al., 2010).

Developing a high-throughput linkage map is crucial for detecting quantitative trait loci (QTLs) associated with agronomically important traits in strawberries. Over the last decade, the IStraw 90 K and IStraw35 384HT Axiom SNP arrays have been improved through the RosBREED project, supported by the cooperation of international researchers (Bassil et al., 2015; Verma et al., 2017; Karci et al., 2022). Thus, these arrays can facilitate the identification of the QTLs and provide high-quality genome scanning with reduced costs for octoploid strawberry breeding programs all over the world.

The primary objectives of plant breeding programs are the development of disease-resistant cultivars and the improvement of existing cultivars (Faedi et al., 2004). Diseases caused by pathogens, in particular, limit strawberry production and are a major challenge in strawberry breeding. Therefore, identifying promising cultivars with resistance to diseases has become a crucial goal in strawberry breeding programs due to the widespread negative effects of these diseases. There are numerous postharvest diseases, such as *B. cinerea*, *Penicillium* spp., *Mucor* spp., *Rhizopus stolonifer*, *Colletotrichum* spp., etc., which not only cause economic losses but also produce mycotoxins that can affect human health if consumed. In particular, *B. cinerea* can significantly reduce yield and postharvest quality in Türkiye and other strawberry growing regions worldwide (Braun and Sutton, 1987; Sutton, 1998). Strawberries may suffer mechanical damage during harvest and storage due to their soft flesh, which can also lead to rot afterward. This damage increases their susceptibility to postharvest diseases. Developing superior cultivars resistant to gray mold in strawberry breeding is a challenging process. To date, strong genetic sources with natural resistance have not been identified, and there are significant differences in disease resistance among strawberry cultivars and genotypes. Despite challenges arising from the complex genetic structure of the strawberry genome, significant progress have been made in QTL mapping in plants using DNA markers and advanced bioinformatic methods.

The developing of a genetic map is an initial step in separating whole subgenomes and performing marker-assisted breeding in *F. × ananassa*. In the last decade, the whole genome chromosomal sequences of diploid *F. vesca* were first released (Shulaev et al., 2011). A high-resolution genotyping based on SNP in *F. × ananassa*, IStraw90 Axiom array, was developed by Bassil et al.

(2015). The construction of high-resolution SNP linkage groups based on the Axiom array in the *F<sub>1</sub>* strawberry populations included 6594 and 8407 SNPs in previous findings, respectively (Bassil et al., 2015; Sargent et al., 2015). Additionally, double digest restriction-associated DNA sequencing (ddRAD-seq) and diversity array (DArT-seq) technologies have been performed for high-throughput linkage maps in strawberries (Davik et al., 2015; Sánchez-Sevilla et al., 2015). The publication of the *F. × ananassa* reference genome is highly valuable for the fast and more cost-effective identification of single nucleotide polymorphisms (SNPs) at the genome level in the development of high-density linkage maps (Hossain et al., 2019; Labadie et al., 2022). To date, QTLs with either minor or major effects on traits related to resistance to pathogens such as *Verticillium dahliae* (Antanaviciute et al., 2015), *Colletotrichum acutatum* (Salinas et al., 2019), and *Phytophthora cactorum* (Nellist et al., 2019) have been detected in strawberries.

The aims of the present research are as follows: (i) the development of high-resolution genetic linkage maps using SNP markers obtained from Fana array (Axiom), and (ii) the detection of QTLs associated with gray mold disease caused by *Botrytis cinerea* using the 'Fortuna × Rubygem' *F<sub>1</sub>* population in strawberry.

## 2. Material and methods

### 2.1. Plant material and DNA extraction

Susceptibility across *B. cinerea* of *F. × ananassa* Duch. cultivars 'Fortuna' and 'Rubygem' was identified in the PRIMA Med-Berry project. In the current paper, the tolerant 'Fortuna' and sensitive 'Rubygem' strawberry cultivars were used as female and male parents, respectively, for the construction of the *F<sub>1</sub>* population. Intraspecific *F<sub>1</sub>* accessions were used in the current study for developing linkage maps and performing QTL analysis. The crosses between 'Fortuna' and 'Rubygem' ('Fortuna × Rubygem') were performed in 2019. The leaf samples from 164 *F<sub>1</sub>* hybrids were collected for DNA isolation from Yaltır Agricultural Products Inc. (Adana, Türkiye).

The genomic DNA samples were isolated using the CTAB (cetyltrimethylammonium bromide) method (Doyle and Doyle, 1987), with several minor modifications according to Kafkas et al. (2005). The quality of the genomic DNA samples was assessed using 0.8% agarose gel electrophoresis. DNA concentration was measured using both agarose gel electrophoresis and fluorometer (Qubit, Invitrogen).

### 2.2. Phenotyping of gray mold resistance

Phenotypic observations of *B. cinerea* in the 'Fortuna × Rubygem' *F<sub>1</sub>* individuals and their parents were performed. These observations were carried out on the leaves and fruits of *F<sub>1</sub>* strawberry progenies. The levels

of *B. cinerea* infection in the fruits and leaves of cultivars were determined, and *B. cinerea* was cultured following the methods described by Siedliska et al. (2018). Both trials for *B. cinerea* resistance on leaves (BC\_L) and fruits (BC\_F) in the 'Fortuna × Rubygem' F<sub>1</sub> strawberry population were evaluated for each individual. Histograms depicting the frequencies of leaf and fruit measurements were created to illustrate the distribution of these traits.

### 2.3. SNP genotyping with Fana Axiom array

An intraspecies linkage map of 'Fortuna × Rubygem' F<sub>1</sub> population was created using the Fana Axiom array, which is composed of 49,483 Affymetrix SNP markers, including 5919 markers from the previous 35K SNP diploid *F. vesca* array and 43,664 from the 90K SNP octoploid array (cultivar Camarosa). Variant calling was conducted using the Affymetrix Power Tools (APT) software. SNP classification was divided into six categories using the default parameters of the APT software, as described by Nagano et al. (2017).

### 2.4. Development of genetic linkage maps

The genetic maps of the 'Fortuna × Rubygem' F<sub>1</sub> strawberry population were created using multilocus ordering algorithm in the MultiPoint program (Mester et al., 2003). The poly high-resolution SNPs (PHR-SNPs) for each linkage were organized into multiple linkage groups (LGs) using the color map method (Kiss et al., 1998). This method involved comparing graphical genotypes derived from segregation data. During the mapping of the color process, reciprocal genotypes were transformed into coupling genotypes. The reliability of all LGs was confirmed using the logarithm of odds (LOD) threshold of 2.0 with the Grouping Module of MultiPoint 3.3 (MultiQTL Ltd, Haifa, Israel). The frequencies of recombination distances in the linkage were expressed in centimorgans (cM). We employed the Kosambi mapping function (Kosambi, 2016) and a regression mapping algorithm for the development of the map. The final visualization of these linkage groups was created using MapChart v2.2 on the Windows platform (Voorrips, 2002). In the segregation description, if both parents were heterozygous (hk × hk), the markers were referred to as 'common.' If one parent was heterozygous (nn × np (male) and lm × ll (female)), the markers were termed as 'parental.'

### 2.5. QTL analysis

A general interval mapping approach was used to identify QTL through a comprehensive genome-wide scan (Korol et al., 1998). A mixture-model strategy was employed using MultiQTL software with ML algorithms (Korol et al., 2001). Initially, a single-QTL model was established and evaluated for significance for each combination of trait and chromosome. Subsequently, the significance of all effects was evaluated by considering the false discovery rate to

control for experimental-wise significance (Benjamini and Hochberg, 1995). The identified QTL effects were denoted according to the nomenclature outlined by McIntosh et al. (2001). It is worth noting that, in several instances, a notable colocalization of QTL was observed for different traits, indicating potential pleiotropic effects of the corresponding QTL or tight linkage among multiple QTL. These situations were challenging to resolve due to the number of samples used in the current study (n = 164).

## 3. Results

### 3.1. Development of a high-density genetic linkage map

A total of 49,483 SNPs based on the Fana Axiom array were categorized with six classifications: polymorphic or nonpolymorphic natures in accessions. Specifically, 28,697 SNPs (58.0%) were classified as poly high resolution (PHR, codominant segregation), 12,949 SNPs (26.2%) as no minor homozygote (NMH, dominant segregation), 5586 SNPs (11.3%) as mono high resolution (MHR) (AA or BB), 469 SNPs (0.9%) as off-target variant (OTV), 671 SNPs (1.4%) as call rate below threshold (CRBT), and 1111 SNPs (2.2%) as others (Table 1). After filtering according to MAF < 0.05, missing data > 5%, and SNPs of replicates of the parents, 24,415 PHR-SNPs, 3419 NMH-SNPs, and 233 MHR loci were mapped onto 33 LGs (Tables 1 and 2).

Finally, 1946 SNP markers were used to map 33 linkage groups, with a length of 1814 cM in the 'Fortuna' map and 2170 cM in the 'Rubygem' map, integrated with Fana Axiom array (Table 2; Figure 1). In 'Fortuna,' a total of 681 common (hk × hk, 1:2:1) and 270 parental (lm × ll, 1:1) markers were identified, accounting for 71.61% and 28.39%, respectively. The lengths of the linkage groups varied, ranging from 3.4 cM (LG32) to 116.8 cM (LG9), with an average length of 55.0 cM. The map resolution was characterized by an average marker density of one marker every 0.59 cM, with the longest marker interval observed in LG22, which was 3.36 cM. In 'Rubygem,' 691 common (hk × hk, 1:2:1) and 304 parental (nn × np, 1:1) markers were recorded, accounting for 69.45% and 30.55%, respectively. The shortest linkage group was calculated as 12.1 cM in LG14, while the longest was detected as 199.1 cM in LG9. The average marker density of 'Rubygem' map was 0.54 cM, and the average marker distance was found to be 2.19 markers per cM. Details of the linkage group-wise markers, marker densities, and genetic distances for the 'Fortuna × Rubygem' F<sub>1</sub> population were provided in Table 1, and the SNP positions and their linkage groups were presented in Supplementary Table S1.

### 3.2. Phenotyping of the traits and QTL mapping

The phenotypic parameters assessed in the F<sub>1</sub> population showed variations among plants; BC\_L and BC\_F were observed in both the 2021 and 2022 growing seasons. The frequency distribution for *B. cinerea* resistance showed

**Table 1.** Classification of detected SNPs.

Classes	Number of raw SNPs	Ratio (%)	Number of mapped SNPs	Mapped ratio (%)
PHR	28,697	58.0	24,415	49.3
NMH	12,949	26.2	3419	6.9
MHR	5586	11.3	233	0.5
OTV	469	0.9	-	-
CRBT	671	1.4	-	-
Other	1111	2.2	-	-
<b>Total</b>	<b>49,483</b>	<b>100</b>	<b>28,067</b>	<b>56.7</b>

MHR: mono high resolution; CRBT: call rate below threshold; NMH: no minor homozygote; OTV: off-target variant; PHR: poly high resolution (PHR).

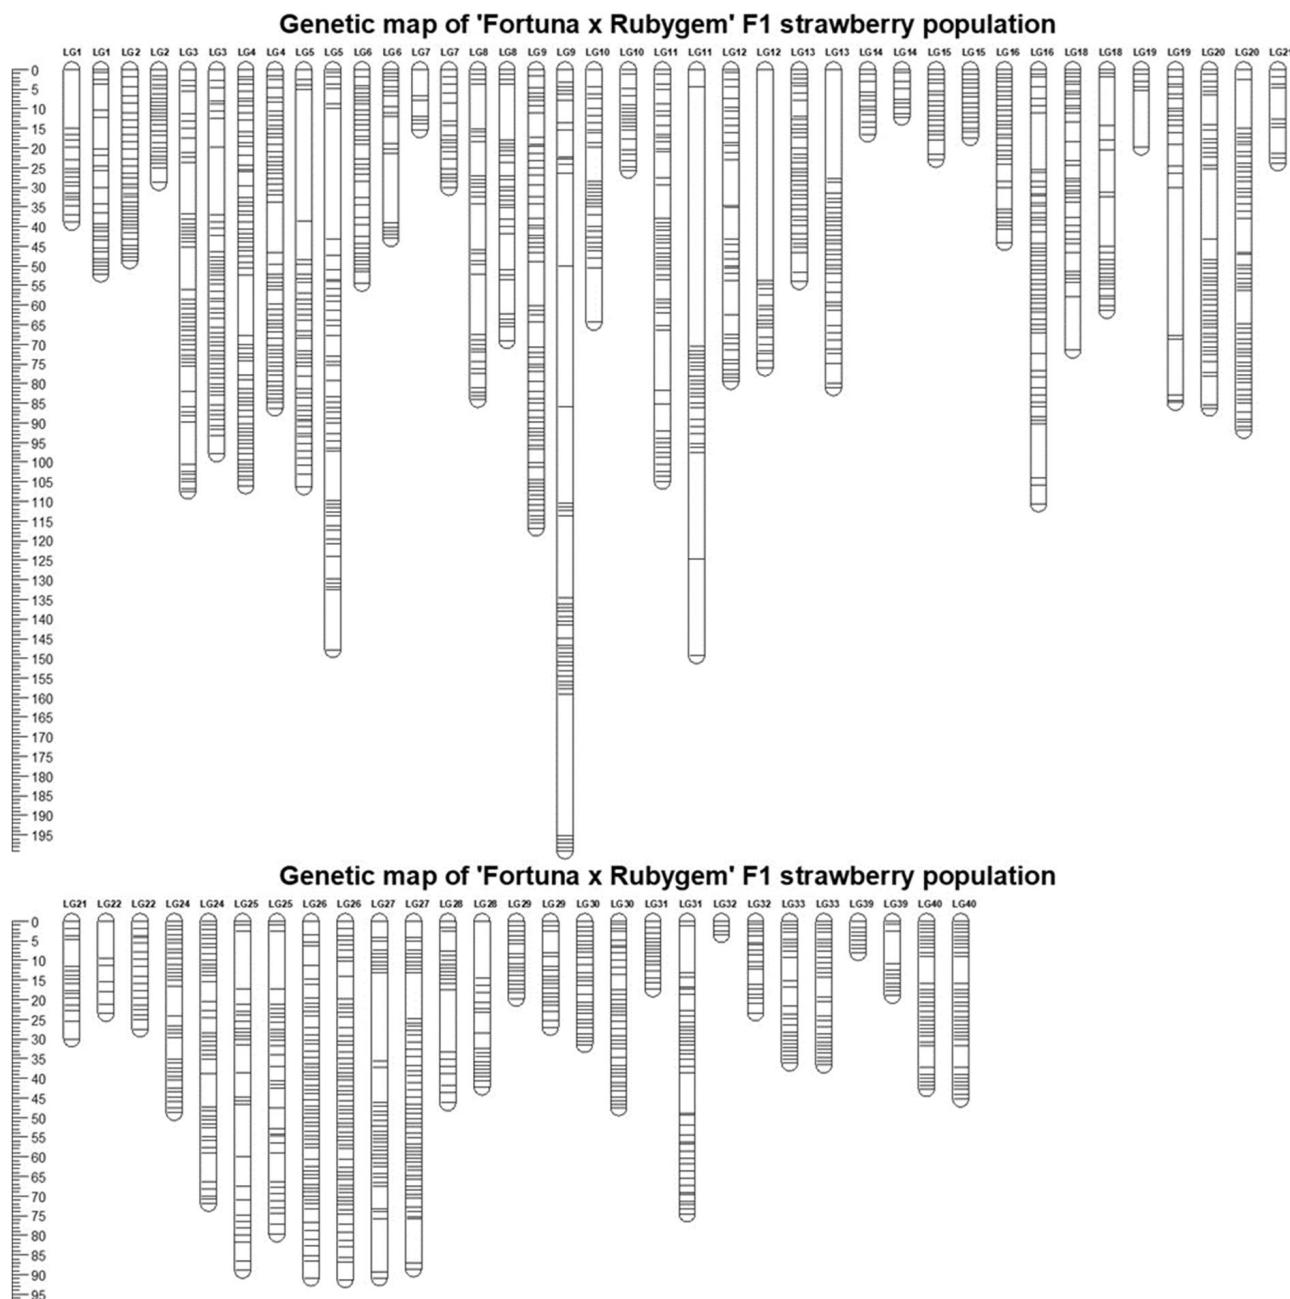

Most of the used SNPs were derived from PHR.

**Figure 1.** SNP-based linkage map of the *F. × ananassa* mapping population derived from the 'Fortuna x Rubygem' F1 strawberry population.

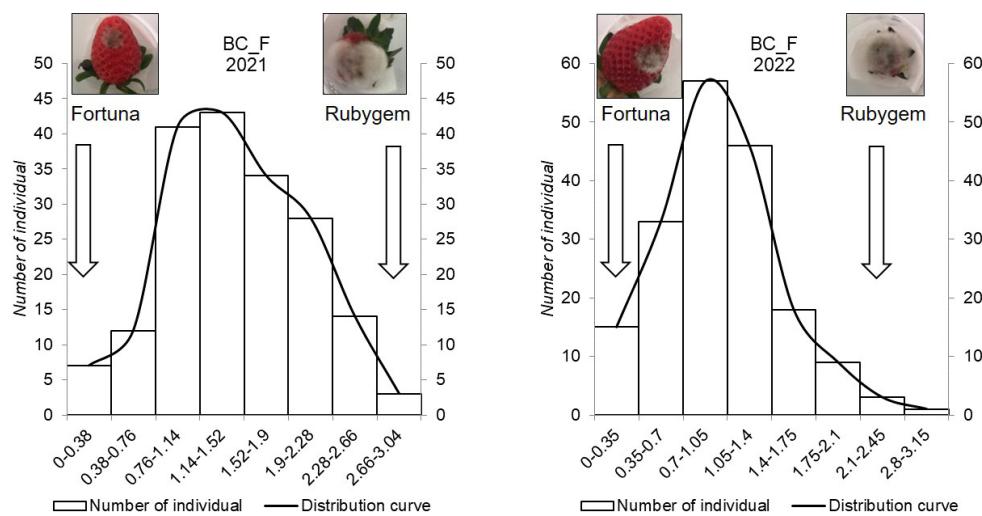

the expected normal distribution among plants. The resistant 'Fortuna' and susceptible 'Rubygem' parents exhibited extreme responses to Bortytis in trials on both leaves and fruits, resulting in a wide range of variation within the population. The distribution histograms and curves showing the range of resistance degrees in *B. cinerea* parents are provided in Figures 2 and 3.

We identified three significant QTLs located in 'Fortuna' and five QTL regions and associated loci on linkage groups in LG6, LG16, and LG33 related to the *B. cinerea* resistance on leaves (BC\_L), using F<sub>1</sub> population derived from crossing 'Fortuna' × 'Rubygem' (Table 3; Figure 4). In 'Fortuna', the significant linked loci in LG6, LG16, and LG33 were

determined as Ax-184251409, Ax-123614760, and Ax-166505239 at 25.31, 36.65, and 0.00 cM, respectively. These markers were found to correspond to the chr4D, chr6, and chr3 in the strawberry genomes. Although the loci Ax-184251409, Ax-123614760, and Ax-166505239 were identified in both the 'Fortuna' and 'Rubygem' maps, the loci Ax-184297806 and Ax-184047067 were only found in 'Rubygem' at 72.36 and 25.53 cM, respectively (Table 3). The highest associated loci (Ax-184047067) on LG16, with the highest LOD score of 2.90 ( $p < 0.005$ ), was calculated and explained the highest proportion (9.80%) of phenotypic variation ( $r^2$ ) among the identified QTLs. The determined QTL region was detected between the flanking markers Ax-184033341 and Ax-184231551

**Figure 2.** Frequency distribution of score of resistance to *B. cinerea* in strawberry leaves in the Fortuna maternal and Rubygem paternal and their progenies.

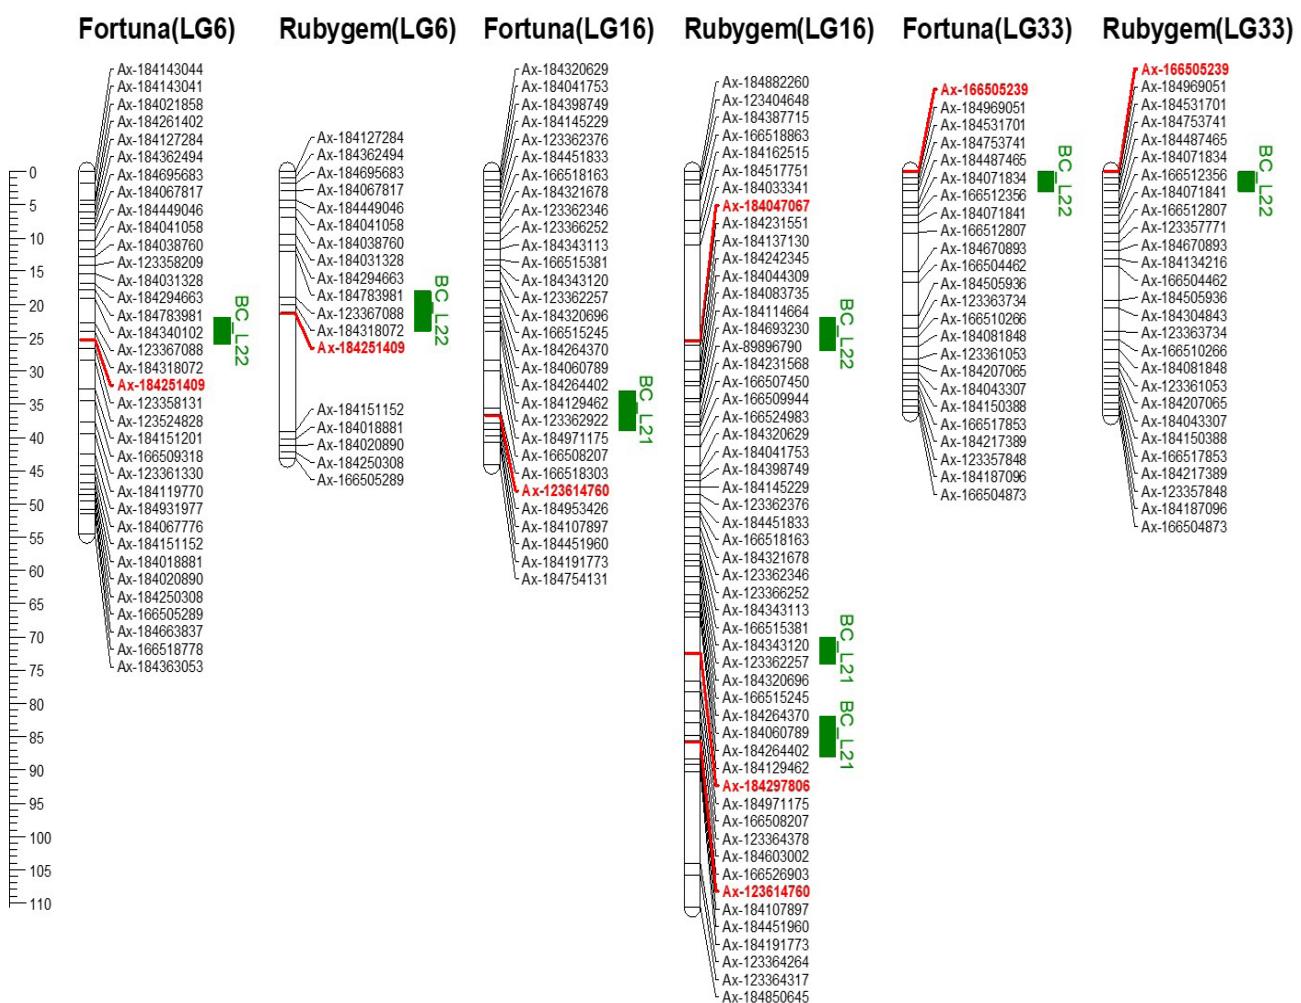

**Figure 3.** Frequency distribution of score of resistance to *B. cinerea* in strawberry fruits in the Fortuna maternal and Rubygem paternal and their progenies.

**Table 3.** Marker positions, panels, corresponding chromosomes (Chrs), LOD score, phenotypic variance (PV%), segregations, and significance of markers linked to resistance to *B. cinerea* in strawberry leaves (BC\_L) from the 'Fortuna × Rubygem' population.

**Figure 4.** QTL regions associated with resistance to *B. cinerea* in strawberry leaves.

(11.00–26.10 cM) on linkage group 16 of the ‘Rubygem’ map. The range of the flanking markers for this QTL was identified on the chr6 within the 13 Mb physical position of the first subgenome in the strawberry genome.

The significant loci associated with resistance to *B. cinerea* in fruits of the ‘Fortuna × Rubygem’ F<sub>1</sub> strawberry population were identified over two consecutive years. The linked loci were found in LG5, LG20, and LG28 in ‘Fortuna’, while associated loci were identified in LG20 in ‘Rubygem’ (Table 4; Figure 5). In ‘Fortuna’, the significantly linked loci in LG5, LG20, and LG28 were Ax-184547649, Ax-123360550, and Ax-184191302, located at 103.21, 49.39, and 37.01 cM, respectively. The alignment of these markers corresponded to the chr3A, chr2, and chr6B in strawberry genomes, respectively. The locus associated with Ax-123360550 was found in LG20 on both maps within the chr2 iStraw35 genome. In ‘Rubygem’, a total of two QTL regions were identified in LG20, with Ax-184051916, and Ax-123360550 located at 47.21 and 50.76 cM, corresponding to chr2D and chr2, respectively. The range of the flanking markers on LG20 and the identified locus in both parents (Ax-123360550) were found within the chr2 iStraw35 genome on three Mb physical positions (Table 4; Figure 5). Additionally, the investigation of the regions controlling resistance to *B. cinerea* demonstrated that the ‘Fortuna’ and ‘Rubygem’ parents have distinct resistance mechanisms due to their extreme responses to *B. cinerea*, with ‘Fortuna’ being tolerant and ‘Rubygem’ sensitive. When compared to the ‘Rubygem’ map, the QTL intervals on LG5 and LG28, which correspond to chr3A and chr6B in ‘Fortuna’, might be influenced by *B. cinerea*.

The detected loci associated with BC\_L and BC\_F were annotated to the latest versions of the *F. × ananassa* and *F. vesca* strawberry genomes using an updated gene information file. Although the markers were not classified as nonsynonymous or synonymous due to incomplete gene

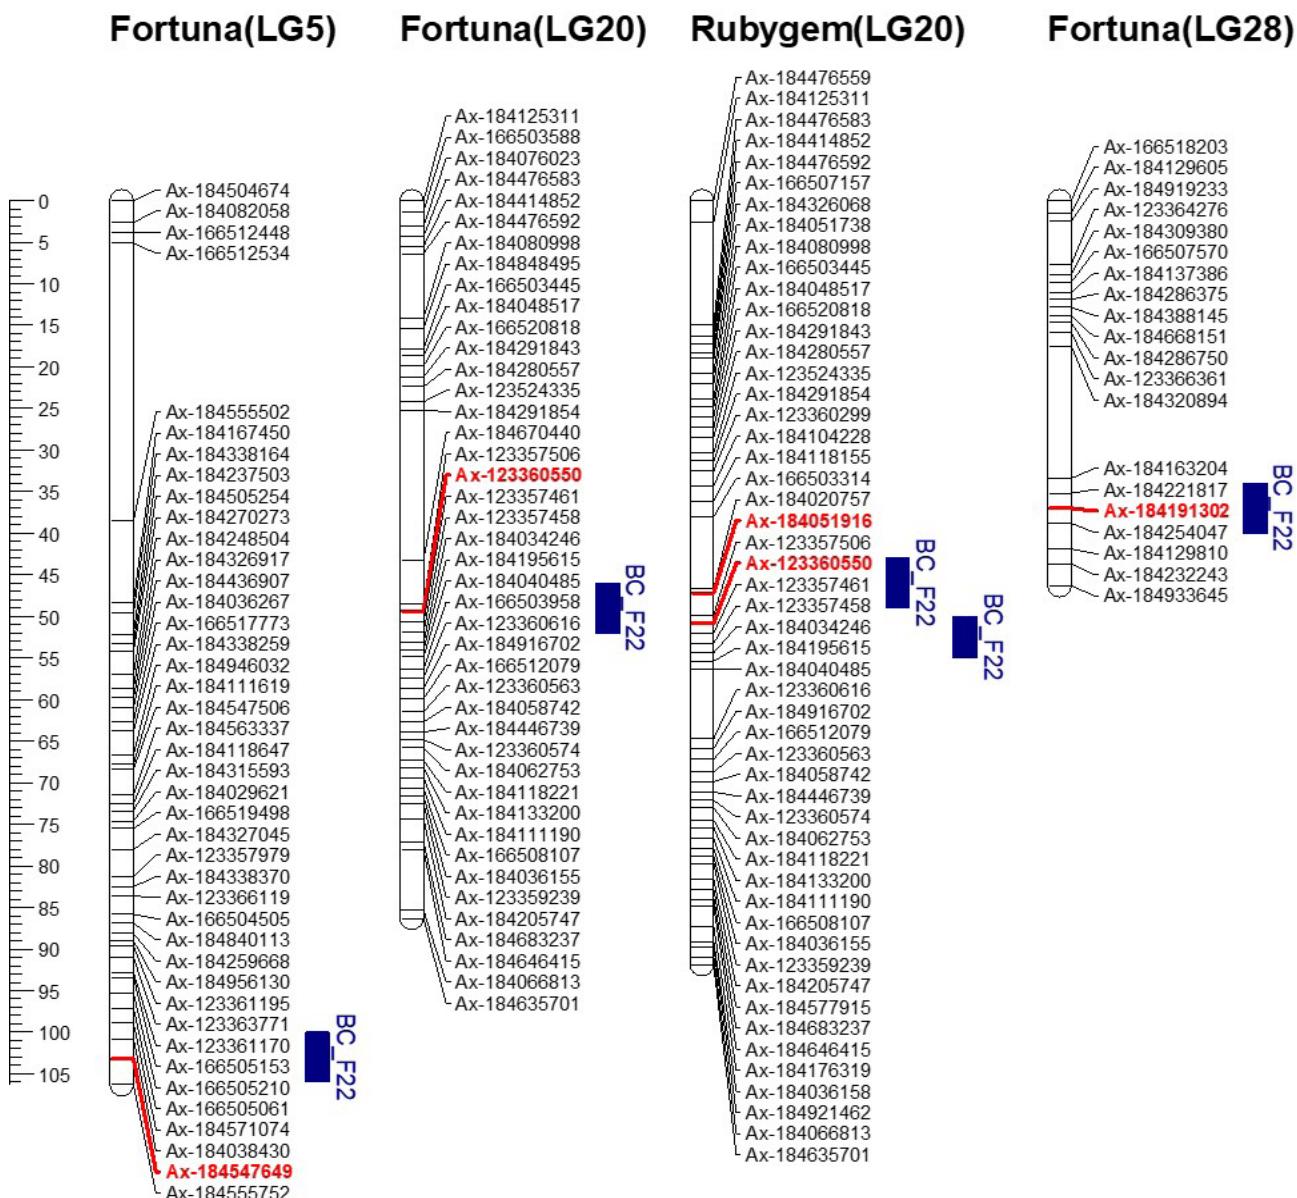

information (gff), the marker/genes associated with genomic regions from strawberry genomes were obtained from the Genome Database for Rosaceae (GDR). The Ax-184251409 marker linked to BC\_L was located on the subgenome of chr4 and was found to control the *FxaC\_14g19050* gene. The other linked marker, Ax-184297806, was identified in the first subgenome of the chr6 within the *FxaC\_21g50810* gene, which is responsible for BC\_L. Ax-184297806 marker located gene plays a role in the synthesis cellular component related to nuclear factor kappa-B-binding protein (IPR024867). The markers linked to BC\_F, such as Ax-184051916 and Ax-184191302, were detected on the last subgenome of the chr2 and the second subgenome of the chr6, respectively. These markers were identified within the *FxaC\_6g23420* and *FxaC\_23g50910* corresponding genes (Supplementary Table S2).

### 3.3. Distribution of SNPs to Fana array

In total, 33 LGs were distributed to seven HGs according to the combined *F. vesca* and *F. × ananassa* genome, Fana Axiom array. The number of linkage groups overlapping with HGs was detailed for both parents. Three of the seven HGs (HG1, HG3, HG7) consisted of four LGs; the other three HGs (HG2, HG4, HG5) were matched with five LGs; and the remaining HG, HG6, comprised six LGs in both the ‘Fortuna’ and ‘Rubygem’ maps. The highest level of synteny was found in subgenome II (SGII) and a total 274 SNPs was mapped to *F. vesca* genome, in ‘Fortuna’ map. In ‘Rubygem’, the highest collinearity was observed in SGI and SGII, with a total of 184 and 180 SNPs, respectively. Additionally, a total of 837 PHR, 64 NMH, and 2 OTV markers in ‘Fortuna’, and 857 PHR, 92 NMH, and 2 OTV markers in ‘Rubygem’ were successfully mapped (Table 5). Detailed information about the comparative analysis of homoeologous linkage groups across *F. vesca* and Fana array was presented in Supplementary Table S3.

**Table 4.** Marker positions, panels, corresponding chromosomes (Chrs), LOD score, phenotypic variance (PV%), segregations, and significance of markers linked to resistance to *B. cinerea* in strawberry fruits (BC\_F) from the ‘Fortuna × Rubygem’ population.

#### 4. Discussion

In the current study, 28,067 out of 49,483 SNP loci were mapped to the reference genome. After applying several filtering parameters, a total of 33 linkage groups with 1946 SNPs were observed in 'Fortuna' × Rubygem' F<sub>1</sub> strawberry population. The lengths of both maps in this population were calculated to be 1814 and 2170 cM, respectively. Several previous studies have revealed that the lengths of linkage maps and the number of mapped loci vary among different strawberry species based on the sequencing platforms used (Bassil et al., 2015; Mahoney et al., 2016; Hossain et al., 2019). The distance of the locus per cM in SNP-based linkage maps was calculated to be 0.91 in diploid *F. vesca*. Although the average marker distance was detected as 2.43 and 2.71 cM/marker in *F. vesca* ssp. *bracteata* (Tennessen et al., 2014), this value was identified as 0.91 cM/marker in ancestral *F. iinumae* (Mahoney et al., 2016). Recently, Hossain et al. (2019) published a high-resolution genetic map developed using ddRAD-seq SNPs in *F. × ananassa*, revealing that the average marker distance was 2.22 cM/marker. The researchers also addressed the marker density as 0.50, while the marker density in the current study was found to be 0.58 and 0.53 in the maternal and parental maps, respectively. Additionally, the average marker distances were identified as 1.92 cM/marker for the 'Fortuna' map and 2.19 cM/marker for the 'Rubygem' map in this study. In total, 31 linkage groups were created using the S1 population of octoploid strawberries for the separation of loci-specific subgenomes of *F. × ananassa* and the development of a linkage map (Nagano et al., 2017). The total length of the 'Reikou' linkage map in the S1 population was determined to be 2,816 cM. Previous studies by Bassil et al. (2015) and Sargent et al. (2015) reported shorter maps compared to

the S1 population derived from 'Reikou' cultivar. Nagano et al. (2017) mapped a total of 8588 SNPs distributed among subgenomes. These mapped SNP loci were found to be higher than in the previous linkage mapping studies due to the larger number of mapped SNP loci. Specifically, Bassil et al. (2015), Sargent et al. (2015), and Hossain et al. (2019) mapped 6593, 8407, and 1268 SNPs, respectively. The sequencing platform and calling errors affect the number of loci and the total lengths of LGs depending on the genetic variation between parents. The high-density linkage map, which is well-covered with subgenomes and includes accurately called variants, increases the chances of detecting loci associated with traits in QTL analysis.

The distinct findings in developing the genetic mapping in *F. × ananassa* observed variations in the number of LGs and lengths (Bassil et al., 2015; Sargent et al., 2015; Davik et al., 2015; Nagano et al., 2017). In previous studies, the number of linkage groups was calculated to be more than the seven homoeologous groups with four subgenomes, similar to the findings in the current report. Generally, polymorphic loci were expected to segregate into distinct genotypes based on their subgenome specificity. If variations in linkage groups and lengths are observed in genetic maps, there are possible reasons for this situation. First, the Axiom array system sometimes misclassified nonspecific loci, and biparental linkage maps were developed using the Axiom array in octoploid *F. × ananassa* (Davik et al., 2015; Nagano et al., 2017). Consequently, the linked loci were spread across the linkage map without clear differentiation from nonspecific loci. The researchers stated that the linkage groups with Axiom array might have been missed from the linkage map due to the monomorphic structure among subgenomes, and that discrepancies with the *F. vesca* genome could be

attributed to assembly errors or incompleteness. Overall, the studies concluded that subgenome-specific sequences were randomly distributed across the *F. × ananassa* genome, with notable differences among the subgenomes in the number of LGs and their lengths (Bassil et al., 2015; Sargent et al., 2015; Davik et al., 2015; Nagano et al., 2017).

Similar results were observed in the current paper compared to the expected outcomes. However, this report utilized a more comprehensive version of the *F. × ananassa* octoploid strawberry genome cultivar 'Camarosa,' published by Edger et al. (2019), which includes homoeologous chromosomes and subgenomes. The complex genome structure of strawberry, including its octoploid ploidy and the genome of *F. × ananassa*, has been published recently. It has become clear that many genomic processes still need to be explored in future research. This study illustrates the constraints faced in performing genome and functional annotations of the linked loci. As mentioned in the previous section, addressing major challenges such as population structure with genomic inheritance, applied sequencing platforms, errors during assembly, and incomplete subgenomic fragments should be priority research areas in strawberry breeding studies.

*B. cinerea* is difficult to control with various fungicides because it is an airborne pathogen active throughout the year. Furthermore, the host-pathogen relationships are complex, and these pathogens rapidly develop resistance mechanisms to fungicides due to the repeated application of certain chemicals (Williamson et al., 2007; Cosseboom et al., 2019; Zhang et al., 2019; Caseys et al., 2021). Early diagnosis of fungal contamination in strawberries is crucial, as it directly affects producers and consumers through its effects on storage, transportation, and marketing, and product safety (Siedliska et al., 2018). The resistance mechanisms of *B. cinerea* are quantitative (Finkers et al., 2007; Williamson et al., 2007; Seijo et al., 2008; Petrasch et al., 2019; Caseys et al., 2021). Identifying the genes responsible for resistance to complex diseases, such as *B. cinerea*, is a lengthy process due to the complex genomic structures of necrotrophic pathogens such as *B. cinerea* and the wide genetic variation in resistance or susceptibility to diseases among strawberry cultivars and genotypes. To address this challenge, a report on the genome-wide resistance to gray mold in strawberries was performed by Petrasch et al. (2022). They identified the QTLs associated with gray mold in five full-sibling families using the 50 K Axiom SNP array developed by Hardigan et al. (2020). A total of nine QTLs were detected in various populations, with the highest significance based on LOD scores. These QTLs were distributed across pseudochromosomes 3, 4, 5, and 7 within different subgenomes. Given that these identified QTLs were characterized as minor and exhibited small effects, it suggests that the genes responsible for

gray mold susceptibility may be controlled by polygenes. On the other hand, a biparental population derived from the tolerant 'Fortuna' and sensitive 'Rubygem' cultivars exhibited a wide range of polymorphism for *B. cinerea* in this study. In the more southern regions, the strawberry cultivar 'Fortuna,' which was improved in California, has been introduced into both public and private breeding programs in Florida (Mezzetti et al., 2018). However, 'Fortuna' and 'Rubygem' were not challenging enough to pose a serious problem for *B. cinerea*, and there has been no comprehensive study on *B. cinerea* in the literature (Herrington et al., 2007). In the current report, the response of 'Fortuna' and 'Rubygem' cultivars to *B. cinerea* infection in leaves and fruits was identified, along with putative genomic regions and QTLs, in an *F<sub>1</sub>* population for the first time. Additionally, the commercial strawberry cultivars 'Fortuna' and 'Rubygem' were recorded as resistant and sensitive to *B. cinerea* for the first time thanks to the present project. The candidate-associated loci for *B. cinerea*, using the genetic variability of the parents, were identified in distinct LGs corresponding to different nonspecific and subgenome-specific regions. On the other hand, QTLs in 'Fortuna' linked by *B. cinerea* on fruits have two additional distinct locations that overlap with chr3A and chr6B homoeologous. However, the common responsible interval in LG20, which is collinear with chr2 and its subgenome, was detected in both maps. Thus, we hypothesized that the transfer of *B. cinerea*-controlling genes or genomic fragments from parents to *F<sub>1</sub>* plants during meiosis, in crosses related to resistance, was predominantly inherited from the 'Fortuna' parent.

SNP markers within the genes associated with resistance to *B. cinerea* can affect phenotypes directly or indirectly. Nonsynonymous SNPs (nsSNPs) result in a change in the amino acid sequence of the protein encoded by the gene. These variations can contribute to phenotypic diversity and influence plant traits within QTL regions (Wang et al., 2017; Rifat et al., 2022). Synonymous SNPs (sSNPs) do not change the amino acid sequence of the encoded protein due to the degeneracy of the genetic code. However, sSNPs can still affect QTL and plant traits through regulatory regions, RNA stability, splicing, and linked variations. sSNPs can occur within regulatory regions of a gene, such as promoter or enhancer regions (PS et al., 2017; Karci, 2023). To describe SNPs according to their positions, the genome annotations for the highest correlated markers associated with gray mold were performed using *F. × ananassa* transcriptome genome database. While only a few markers could be defined, most of them were not detected through gene ontology and biochemical compound analyses. In addition, reports on similar topics in the literature have not classified SNPs according to genome annotation results, such as exonic,

intronic, intergenic, etc. (Davik et al., 2015; Nagano et al., 2017; Hossain et al., 2019). The potential causes of this annotation issue were investigated, including the possibility that the subgenome-specific transcriptome sequences were incomplete or that the .gff file had been rearranged during the research on the complete genic information in strawberries.

In plants, the probability of selecting superior genotypes in terms of features such as disease resistance, which involve complex genetic mechanisms, is relatively low. Genetic linkage mapping and QTL studies associated with key traits provide valuable genetic information for understanding complex traits, such as resistance to *B. cinerea*. Therefore, developing candidate markers associated with these traits, understanding the genetic mechanisms, and identifying the genomic positions of such complex traits will provide valuable information for breeders and geneticists to accelerate progress in strawberry breeding programs (Kim et al., 2014). The investigations aimed to control pre- and postharvest processes by combining the classical and modern breeding approaches, thereby saving time and labor from field to market and reducing significant product loss due to *B. cinerea*.

## 5. Conclusion

This study is one of the first QTL studies conducted using a high-density genetic map to investigate resistance

to *B. cinerea* using the F<sub>1</sub> population derived from the crossbreeding of 'Fortuna' and 'Rubygem' strawberry cultivars. In terms of resistance to *B. cinerea*, after inoculations and assessments performed on leaves and fruits in 2021 and 2022, linked loci in different LGs were identified in the 'Fortuna' and 'Rubygem' maps. The obtained data will be valuable for understanding the resistance mechanism of *B. cinerea* and will support breeding programs that enable marker-assisted selection in strawberries.

## Acknowledgments

We would like to thank EU PRIMA (Partnership for Research and Innovation in the Mediterranean Area) Med-Berry project, entitled "Developing new strategies to protect strawberry crop in Mediterranean Area", The Scientific and Technological Research Council of Türkiye (TÜBİTAK) (grant number: TOVAG 118O852), and the Çukurova University BAP Coordination Unit (project no: FDK-2019-12469) for their financial support. We would also like to thank Yaltr Agricultural Products Inc. (Adana, Türkiye) for technical support with the field trials. We would also thank Dr. Beatrice Denoyes and Dr. Aurelie Petit for sharing their sampling and extraction methodologies.

## Conflict of interest

The authors declare that they have no conflict of interest.
