12 **Abstract**

13  
14 The Canary Islands are still largely dependent on expensive imported fossil fuels, are stressed by the  
15 increasing touristic impact and are extremely vulnerable to climate change due to water scarcity.  
16 Water desalinisation is an energy-demanding process and is essential to the sustainable  
17 development of these islands. The aim of this study is to explore the potential advantages of a hybrid  
18 installation, exploiting two different renewable energy sources, specifically waves and solar, to  
19 supply a large desalination plant in Tenerife. The paper ultimately provides a generally applicable  
20 procedure for the design of hybrid installations, including three steps: the assessment of available  
21 renewable energy sources, the optimal combination of these sources and finally the economic  
22 assessment. The wave and solar resources are assessed first, then the hybrid installation is  
23 conceptually designed proposing a criterion for the optimal mixing of the renewable energy sources  
24 that can be applied to other resources and other sites. The basic idea is to maximize the exploitation  
25 of the renewable power, minimizing the need of the fossil-based back-up system. The costs of the  
26 hybrid installation are finally assessed considering the sensitivity to government incentives, showing  
27 that the project parity point is reached within the lifetime of typical desalination plants (i.e. 40 years)  
28 and can be significantly more attractive in case of Feed-In-Tariffs available in other European  
29 countries.

## 1. Introduction

A significant contribution to climate change adaptation may come from marine renewable energy production and from innovative multi-functional offshore installations that may shift offshore part of the anthropogenic pressures (e.g. tourism, aquaculture) on coastal systems (Zanuttigh et al., 2015, 2016). Unlocking the potential of marine resources is crucial to achieve the green energy production goals while preserving the vulnerable marine ecosystem and responding to the increasing demand for energy, food and transportation. Some conversion technologies are consolidated and widely applied, such as fixed wind energy plants, that however cannot be placed in very deep waters, as they require to be drilled in the seabed, with some environmental impact together with some aesthetic impact depending on the distance from shore (Lüdeke, 2017; Durning and Broderick, 2019). Floating wind farms, that can overcome these problems, are under testing, due to the challenging stability issues in extreme conditions (Kausche et al., 2018; Moore et al., 2018; Hannon et al., 2019). Wave energy harvesting is far from being economically feasible, mainly due to the low-efficient technologies of power conversion (Drew et al., 2009) and to design challenges such as the moorings design (Harris et al., 2006; Martinelli and Zanuttigh, 2018). Floating PV-panels have been already installed on pond and lakes and have still to overcome the challenge of the harsh off-shore conditions (Trapani and Redón-Santafé, 2015; Sahu, et al., 2016).

In this context, previous research (FP7 MARINA, ORECCA and SOFIA projects) and prototype testing suggested the combination of different sources of marine Renewable Energy Sources (RES) to increase the active operational time and the economic feasibility of these plants. The potential of combined installations of wind and wave energy has been studied by many authors, among others Fernandez-Chozas et al. (2012), Astariz et al. (2015), Zanuttigh et al. (2015), Contestabile et al. (2017). A review can be found in (Perez Collazo et al., 2015).

Demonstrations of integrated plants have been poorly performed so far, experiences being limited to a few prototypes integrating wind and wave energy, while many conceptual designs at different level of detail do exist (Nassar et al., 2020). New frontiers are being explored with the Wind Power Hub project (2016): a “green” island, consisting of fixed wind piles with a capacity of several GWs, solar panels, plus an airport and a harbour for operation, is expected to be built up on the Dogger Bank by 2050.

Three key original observations are at the basis of this contribution.

64 The first is that wave energy and wind energy are more frequently contemporary rather than  
65 complementary, especially in limited-fetch seas, and therefore it is likely that the combination of  
66 wind or wave with sun would allow to cover the energy needs at a given site for a longer period,  
67 since these sources are naturally “in opposition of phase” as the first ones are maxima during storms  
68 and the latter achieves its peak during good weather.

69 The second is that there are many populated islands (2’200 only in the European Union), most of  
70 which depend on expensive fossil fuel imports for their energy supply. Many of these islands do also  
71 experience problems with transportation and heat, especially during the stormy season, and are  
72 exposed to water scarcity, especially during the touristic season, while being naturally placed in  
73 high-energy locations. The *Clean energy for EU islands* initiative (2017; 2020), launched in 2017,  
74 provides a long-term framework to support their sustainable development by increasing the  
75 production of renewable energy. This in turns leads to the reduction of environmental impacts, the  
76 creation of new jobs and business opportunities, the increase of energy security due to lower need  
77 for imports, and overall, to the improvement of the islands’ economic self-sufficiency.

78 The third is that the combination of renewables is indeed a challenge for energy grids, due to energy  
79 variability, uncertainty, non-synchronous generation, low-capacity factor and distance of the  
80 generation site from the grid.

81 This paper integrates for the first time these three observations by analysing the feasibility of  
82 renewable energy transition for touristic islands, with application to Tenerife, in the Canary Islands.  
83 Specifically, the combination of off-shore wave and on-shore solar energy to locally supply a water  
84 desalination plant is analysed. An objective criterion for the optimal mixing of the RES is proposed  
85 to allow for a general application to other RES and for exportability to other sites.

86 The paper starts from an overview of the site in Section 2, considering the environmental, social and  
87 economic conditions. The selection of wave and solar energy, among the available RES, is also  
88 motivated. Section 3 analyses the available wave energy, including seasonality, and the potential  
89 power production based on one of the more mature technologies for energy conversion. A similar  
90 assessment is performed for solar energy in Section 4. The optimal RES mixing to power the  
91 desalination plant is described in Section 5. The economic assessment is carried out in Section 6, in  
92 terms of the prices required to wave energy to make economically viable the implementation of the  
93 hybrid power generation plant. Conclusions are drawn in Section 7.

## 94           **2. Description of the study area**

95   The aim of this Section is to provide a description of Tenerife Island, including environmental, social  
96   and economic characteristics (Sub-section 2.1). The energy demand and the RES availability is also  
97   specifically addressed (Sub-section 2.2), including the reasons for selecting wave and solar energy  
98   as the most suitable RES to be investigated in the present study.

### 99           **2.1 Overview of the site**

100   Tenerife is the largest, highest and most populated of the Canary Islands, with a land area of about  
101   2'000 km<sup>2</sup>, a maximum elevation that exceeds 3'700 m and more than 900'000 inhabitants at the  
102   start of 2019 (Real Decreto, 2018). Moreover, it is also the most visited island of the archipelago,  
103   with approximately 5M tourists per year and a distributed touristic pressure of about 480'000  
104   visitors per month (Gobierno de Canarias, 2020b).

105   Tenerife hosts many natural heritage observation, conservation and protection areas (Cabildo de  
106   Tenerife, 2019), such as national and natural parks, different types of natural reserves, and sites of  
107   scientific interest as depicted in Figure 1. With regard to marine conservation areas, Hernandez et  
108   al. (2007) classified Tenerife as a Highly Fished Area (HFA), thus outside Marine Protected Areas  
109   (MPA). At present, there are some MPAs in the South-East of the Island and only one MPA near the  
110   coast in the North-East of Tenerife, Anaga (Figure 1), which covers only 8 km<sup>2</sup> (Marine Protection  
111   Atlas). The vast majority of the observations of cetaceans between the years 1997 and 2006 were  
112   recorded along the South-West coast of Tenerife, while few sightings were recorded along the  
113   North-East coast of the Island (Carrillo et al., 2010).

114   From a geological point of view, Tenerife lies on a volcanically active zone with narrow and steep  
115   continental shelf, due to the presence of the sleeping volcano of Mount Teide. Debris avalanche  
116   deposits are present offshore Tenerife and many avalanche events were mapped offshore the  
117   Northern coast (Llanes et al., 2003).

118   Climate in the Canary Islands is mild, due to the influence of the North-North East trade winds and  
119   the cool waters of the subtropical North Atlantic. However, cool trade wind episodically weakens  
120   and easterly Saharan air reaches the Canaries, causing heatwaves with daily temperatures up to 45°  
121   C, drops in relative humidity down to 15% and the presence of suspended desert dust (Dorta, 2007).

122 The Canary Islands are characterized by extreme aridity as precipitations are scarce and irregular  
123 (Rosales-Asensio et al., 2020). After the over-exploitation of the aquifers, water desalination has  
124 been constantly increasing over the last decades to face the development of agriculture, the  
125 increase of tourism and the population growth (Rosales-Asensio et al., 2020). Almost the 30% of  
126 fresh water in the Canary Islands comes from desalination plants, with a peak of the 99% in  
127 Lanzarote (Rosales-Asensio et al., 2020; Garcia-Rubio and Guardiola, 2012).

128

129

130 Figure 1. Map of Tenerife: the striped pattern indicates natural parks, reserves and MPA. The  
131 intersections of the geographical grid correspond to the points where solar data are available  
132 (Sub-section 4.1). The blue and the yellow filled-in circles indicate respectively the positions in  
133 which wave and solar data are collected, while the blue and the yellow crosses individuate the  
134 locations for the WEC and the PV plant respectively (Sub-sections 3.1 and 4.1).

135

136 Nowadays, 299 desalination plants, mostly using Reverse Osmosis (RO) technology, are operating in  
137 the Canary Islands, with a desalinated water volume of about 250 hm<sup>3</sup>/year (Rosales-Asensio et al.,

138 2020). In Tenerife, there are 46 desalination plants with a total production of about 40 hm<sup>3</sup>/year,  
139 covering the 9% of the total water demand of the island.

## 140 **2.2 The energy scenario in Tenerife**

141 At present, only the 8% of the electrical power in the Canary Islands comes from RES, specifically  
142 onshore wind and solar photo-voltaic, 153 MW and 166 MW respectively in 2016 (CEICC, 2016).  
143 Thus, the islands are significantly affected by fossil fuel price shocks and this threat is perceived by  
144 social actors as more relevant than climate change issues (Hernandez et al., 2018). Indeed the cost  
145 of energy in the Canary Islands ranges from a minimum of 0.18 €/kWh in Tenerife up to a maximum  
146 of 0.26 €/kWh in El Hierro, which is 3.5 times the prices at the Peninsula, an extra charge that does  
147 not impact local consumers, but is rather spread around all Spanish energy consumers  
148 (Schallenberg-Rodríguez and García Montesdeoca, 2018).

149 The energy consumption in Tenerife was estimated to be 4.173 kWh per capita in 2016, very close  
150 to the Spanish one of 5.692 kWh per capita (Gobierno de Canarias, 2017). The same year, the electric  
151 generation capacity on the Island exceeded 1200 MW, of which approximately the 93% was  
152 petroleum-derived (mainly through thermal power stations) and only 154 MW were obtained from  
153 RES. The main RES contribution is solar energy (74.6%), the second is on-shore wind energy (23.8%)  
154 and the rest is provided by mini-hydraulic installations and biogas plants (Gobierno de Canarias,  
155 2017).

156 To increase the sustainable development in Tenerife, the potential of new RES installations is  
157 examined. There are no additional potential locations for onshore wind farms in the Canary Islands,  
158 as a consequence of the peculiarity of the territory combined with the legislative limits and with the  
159 aesthetic impact (Schallenberg-Rodríguez and Notario-del Pino, 2014). The legislation is less  
160 restrictive for on-shore solar plants than for wind farms (Schallenberg-Rodríguez and Notario-del  
161 Pino, 2014). Based on the present land use, over 48% of the total land belongs to natural reserves  
162 (Cabildo de Tenerife, 2019), but around the 21% of Tenerife's area would be eligible for solar plants  
163 (Schallenberg-Rodríguez and García Montesdeoca, 2018).

164 Schallenberg-Rodríguez and Montesdeoca (2018) explored areas for offshore bottom-fixed and  
165 floating wind installation, finding nearly the 12% of the territorial waters available for such purpose,  
166 and estimated a power production up to 180 TWh per year (i.e. around 22 times the total annual  
167 energy consumption of the Canary Islands). According to these authors, Fuerteventura, Lanzarote,

168 Gran Canaria, and Tenerife could be fully powered by the energy generated by traditional fixed  
169 turbines installed at a depth of 50 m, while La Palma and El Hierro would mainly depend on floating  
170 turbines.

171 After Schallenberg-Rodriguez and Montesdeoca (2018), the only option of off-shore fixed wind  
172 energy would be economically viable for Tenerife. However, despite promising, off-shore wind  
173 energy was not considered in this study because of the piles environmental impact, of the low social  
174 acceptability caused by the visual impact and because of the submarine daily seismic activity (Carniel  
175 et al., 2008; Volcano Discovery, 2020).

176 Following the outcomes of previous research on multi-use marine platforms in the Canary Islands  
177 (a.o. the FP7 TROPOS and the H2020 MUSES European projects), the marine renewable installation  
178 will be a floating installation and will consist of a single unit or an array of wave energy devices  
179 (Section 3). Wave energy will be combined with a new installation of solar on-shore plant (Section  
180 4). The integration of these resources will then be considered to provide the power supply to the  
181 water desalinisation plant (Section 5).

182 Due to the proximity between the energy source and the infrastructure and considering the issues  
183 related to the connection to the grid, the option to supply a desalination plant with energy  
184 recovered by wave energy converters (WECs) was found to be an interesting solution (e.g. Franzitta  
185 et al., 2016; Leijon and Bostrom, 2018). Fernandez-Prieto et al. (2019), in particular, examined the  
186 opportunity to use wave energy to power a desalination plant in the North of Gran Canaria,  
187 concluding that it could be a feasible solution both from a socioeconomic and from an  
188 environmental point of view. Some prototype desalination plants indeed do already exist that are  
189 partially or totally powered by renewables (e.g. Cipollina et al., 2014; Rosales-Asensio et al., 2019).

190

### 191 **3. Wave energy assessment**

192 This Section analyses the available wave energy and the potential power production of a WEC in the  
193 waters of Tenerife. In Sub-section 3.1 the wave database is described, a suitable area for the  
194 installation is selected and the wave climate at the location is outlined. In Sub-section 3.2, the  
195 available wave power is calculated on an annual, seasonal and monthly basis. Finally, in Sub-section

196 3.3 the most suitable WEC is selected for the installation and the energy production is estimated for  
197 a typical year on a seasonal and monthly basis.

### 198 **3.1 Typical wave climate**

199 The detailed analysis of the wave energy potential of Tenerife Island can be performed based on 61  
200 years of hourly wave data. The dataset covers the period 4 January 1958 - 31 December 2018 at the  
201 SIMAR point 1016015, located North-East off the coast of Tenerife island (28°45'N, 16°00'W), see  
202 Figure 1 and Figure 2. SIMAR dataset consists of hourly series of wave parameters (significant wave  
203 heights  $H_s$ , peak periods  $T_p$  and wave direction) derived from numerical modelling instead from  
204 direct measurements. This dataset, which offers information from 1958 to the present, has been  
205 developed by the Spanish governmental agency Puertos Del Estado, that is responsible for  
206 implementing the government's port policy, with the purpose of providing longer and daily updated  
207 time series of climate parameters. Two models were used to generate the wave fields: WAM and  
208 WAVEWATCH III (WW3), driven by the wind field data from the model provided by AEMET (i.e. the  
209 Spanish national agency of meteorology). The first two are third-generation spectral models that  
210 solve the energy balance equation without making assumptions about the wave spectrum. The  
211 models have been validated with measured data from buoys and satellite data by many authors  
212 (e.g. Goncalves et al., 2014, for the Isle of Gran Canaria and Silva et al., 2015, for the Iberian  
213 Peninsula).

214 Among the points of the SIMAR wave dataset situated around the Island of Tenerife, the selected  
215 point is the most energetic one and is also located in a suitable area (Veigas and Iglesias, 2013),  
216 since the Northern part of the island is not a tourist area, it is not an MPA (see Section 2.1) and it is  
217 far away from nautical trade routes (World seaports catalogue). However, Veigas and Iglesias (2013)  
218 excluded the point from their analysis because of the extreme water depth: in fact, it is located  
219 outside the continental shelf, approximately 22 km off the coast, at a depth of almost 3000 m.  
220 However, according to Gongalves et al. (2020), there is not such a great variation of the annual  
221 average wave power in this area, being it always in the range 16-18 kW/m. Therefore, in this  
222 analysis, the SIMAR point 1016015 dataset was considered in order to assess the wave climate,  
223 although the location for the WEC will be much closer to the shore, on the continental shelf, where  
224 the slope gradient is less than 1° (Llanes et al., 2003). In particular, the chosen location is about 4  
225 km off the coast and 20 km from the port of Santa Cruz, at a depth of about 50 m (Figure 2).

226 For the purpose of this analysis, the direction intervals  $0^{\circ}$ - $40^{\circ}$  and  $300^{\circ}$ - $360^{\circ}$  were selected, being  
227 the more significant for energy generation, as the corresponding fetch is almost unlimited. The  
228 probability of occurrence for each combination of wave directions and wave heights is reported in  
229 Table 1. An example of the wave roses is reported in Figure 3 for a typical year. The  $H_s$  – direction  
230 matrix and the wave roses indicate that most of the waves come from NNE and N directions ( $0^{\circ}$ -  
231  $30^{\circ}$ N and  $350^{\circ}$ - $360^{\circ}$ N) but the highest and most energetic waves come from NW and NNW  
232 directions ( $310^{\circ}$ - $330^{\circ}$ N). By grouping all the selected data based on significant wave heights  $H_s$  and  
233 peak periods  $T_p$ , the most common wave conditions were identified in Table 2. The wave states  
234 characterized by  $H_s$  in the range 1-2 m and  $T_p$  in the range 7-8.5 s have the highest probability of  
235 occurrence. Moreover, the waves with  $T_p > 9$  s are rather frequent and are associated with the  
236 highest values of available wave power.

237  
238 Figure 2. Bathymetry of the sea floor in the North-Eastern area off the coast of Tenerife, between  
239 the SIMAR point 1016015 ( $28^{\circ}45'N$ ,  $16^{\circ}00'W$ ) and the shoreline. The blue cross indicates the  
240 possible area for the WEC installation.

253

### 3.2 Available wave power

254 The wave power can be obtained, for each wave condition, according to Eq. 1:

$$P_w = \frac{\rho g^2 H_s^2 T_e}{64\pi} \quad \text{Eq. 1}$$

255 where  $P_w$  is the wave power per unit of crest length (kW/m),  $T_e$  is the energetic period (assumed to  
256 be  $0.9T_p$ ),  $\rho$  is the water density (assumed to be  $1.025 \text{ kg/m}^3$ ) and  $g$  is the gravitational acceleration.  
257 These values of theoretical wave power, calculated for each wave condition, were multiplied by the  
258 corresponding probability of occurrence to estimate the realistic available wave power  $P$ . The  
259 average annual value of  $P$  over 61 years, is  $P_{y,m} = 18.54 \text{ kW/m}$  (see Table 3). In order to assess the  
260 variability of  $P$  over the years, the same procedure was repeated for each year. The results, reported  
261 in Figure 4, show that there are no significant variations over the years. In particular,  $P$  ranges from  
262 a minimum of  $11.86 \text{ kW/m}$  (in 2009) to a maximum of  $26.71 \text{ kW/m}$  (in 2018), but the years in which  
263  $P$  exceeds  $20 \text{ kW/m}$  are rather rare, as well as the years in which  $P$  doesn't exceed  $15 \text{ kW/m}$ . The  
264 available  $P$  was also calculated on a monthly and on a seasonal basis. The series of estimated  
265 seasonal power data are graphically represented through their quartiles in Figure 5. On average,  
266  $29.39 \text{ kW/m}$  are available during Winter (i.e. 59% more than  $P_{y,m}$ ),  $19.50 \text{ kW/m}$  during Spring (5%  
267 more than  $P_{y,m}$ ),  $16.04 \text{ kW/m}$  during Autumn (13% less than  $P_{y,m}$ ) and  $10.44$  during Summer (44%  
268 less than  $P_{y,m}$ ), with little variation over the years.

269 The column chart showing the variability of the monthly power for year 2016 is reported in Figure  
270 6. Specifically, the year 2016 was selected as reference typical year over the last decade, considering  
271 both the yearly available power ( $20.12 \text{ kW/m}$ ) and the seasonal power distribution ( $31.86 \text{ kW/m}$   
272 during Winter,  $21.34 \text{ kW/m}$  during Spring,  $17.19 \text{ kW/m}$  during Autumn and  $11.48$  during Summer).  
273 In fact, both the yearly average power and each seasonal average power are close to their respective  
274 median value (see Figure 5) and the percentage difference between each seasonal value and the  
275 yearly value is almost exactly equal to the corresponding average value over the observed 61 years  
276 (in particular, 58% more than the annual average value during Winter, 6% more during Spring, 15%  
277 less during Autumn and 43% less during Summer).

278

279

280

Figure 4. Average available wave power  $P$  calculated on an annual basis (kW/m).

In the selection of the most suitable WEC for a particular location, there are many factors to be considered, such as: the distance from shore, the water depth, the visual and the environmental impact, besides the wave climate conditions. Moreover, the power matrix or power curve is freely available only for a few WECs, allowing for the preliminary estimation of the power production.

In the present case, being Tenerife a tourist island, only near-shore and offshore WECs have been considered, in order to minimize the visual impact. Furthermore, the Canaries are volcanic islands, which entails two important consequences: they are characterized by a steep sea bottom, thus great depths are reached close to the coast, and they can be subjected to earthquakes. For these reasons, only floating WECs were investigated.

With regard to the wave climate (Figure 3), most of the waves come from the Northern sector and the wave steepness is quite low for most of the time (Figure 7). Devices whose technology is based on the pitch, like DEXA (Zanuttigh et al., 2010; Martinelli & Zanuttigh, 2018) and Pelamis (Henderson, 2006; Yemm et al., 2012), have therefore to be excluded. On the contrary, long waves with low steepness are a favourable condition for overtopping devices and specifically for terminator devices, given the limited range of wave directionality.

Consequently, the Wave Dragon, WD hereinafter, was selected for the site. The WD (Kofoed et al., 2006; Eskilsson et al., 2014) is an overtopping device operating in the range 1-8 m of  $H_s$  and 4-14 s of  $T_p$ . Among the few devices whose potential production in the various sea states is published, WD is also the only one whose Company is still operating. The main features of WD and its power matrix are reported respectively in Table 4 and Table 5.

The WD was recently selected for possible applications in the Canary Islands by Goncalves et al. (2014, 2020), who compared its performance to the one of Pelamis and Aqua Buoy devices (Goncalves et al., 2014) and also to the one of OceanTec, Seabased and Wavebob (Goncalves et al., 2020), finding that the WD always showed the highest power output.

The output power at the examined site in Tenerife (SIMAR point 1016015) was calculated for the selected reference year, 2016 (see Sub-section 3.2), on an hourly, monthly and seasonal basis (Table 6). A yearly energy production of 13.2 GWh/y was obtained, in agreement with the previous studies. The series of estimated monthly performance and energy data are graphically represented in Figure 8 and in Figure 9 respectively. The WD is always operational during summer, since waves are

320 characterized by a lower amount of energy but they all fall within the operative range of the device.  
 321 During winter, the WD operates approximately 80% of the time, because the longest and more  
 322 energetic waves are beyond the operative range of the device. As a result, the output power over  
 323 the months remains almost unchanged and it is thus equally distributed over the different seasons.

## 4. Solar Power Assessment

345

346

347

348

349

350

This Section analyses the available solar irradiation and the potential power production of a selected PV panel at a chosen location close to Santa Cruz de Tenerife. The database used in the present study is described in Sub-section 4.1, where the hypothetical location of the PV installation is also identified, while the available solar irradiance is reported in Sub-section 4.2 in terms of annual and seasonal average. In Sub-section 4.3, a commercial PV panel is selected and the power produced is estimated for the typical year on a seasonal basis.

351

### 4.1 Solar radiation dataset

352

353

354

355

356

357

358

359

360

Data about solar variables were retrieved from “Copernicus Climate Data Store” provided by the European Centre for Medium-range Weather Forecasts, through the “ERA5” dataset that collects worldwide reanalysis data (ECMWF, 2020). Reanalysis data are generated through a process of “data assimilation”: physical and meteorological models are integrated with measures of critical variables performed on the whole globe (Parker, 2016). “ERA5” data are available for every hour since 1979 and are discretized on a globe grid with a resolution of  $0.25^\circ \times 0.25^\circ$  sexagesimal degrees (24.5 km and 27.8 km in latitude and longitude respectively). In the present case, the last two decades of data (1999-2018) were chosen in order to check seasonal and yearly variations of the solar irradiation on the area of interest.

361

362

363

364

365

366

Since Tenerife is a rather large island, several reticulate nodes of the “ERA5” dataset fall within its borders or in close proximity (see Figure 1). The presence of the peak of Mount Teide should be taken into account in the selection of the more appropriate grid point, since it is better to place the PV installation in an area well exposed to the South. Indeed, existing solar farms are located at the South East of Mount Teide, in Arico and Abona (Gobierno de Canarias, 2017; 2020a). According to ITER (2016), in Santa Cruz only a 100 kW plant is present up to now.

367 Therefore, the industrial area between Santa Cruz de Tenerife and La Laguna was selected for the  
368 present analysis. The closest reticulate point for solar data acquisition is located at 28°50' N and  
369 16°25' W (Figure 1). The necessary raw data extracted from the dataset for the evaluation of solar  
370 irradiation are: (i) the surface net solar irradiation  $H_h$  [J/m<sup>2</sup>], (ii) the direct irradiation  $H_{bh}$  [J/m<sup>2</sup>] and  
371 (iii) the ground albedo  $\rho$  [rad], all referred to a horizontal capturing surface (EMCWF, 2020).

## 372 **4.2 Available solar irradiance**

373 The total solar irradiation  $H$  [J/m<sup>2</sup>] on a surface with any inclination and orientation can be evaluated  
374 from Eq. 2, according to the procedure reported by UNI 8477 (UNI Standards, 1983):

$$H = R H_h = (R_{dir} + R_{diff} + R_{refl}) H_h \quad \text{Eq. 2}$$

375 where  $H_h$  [J/m<sup>2</sup>] is the surface net solar irradiation referred to a horizontal capturing surface, which  
376 consists of the direct irradiation  $H_{bh}$  [J/m<sup>2</sup>] and the diffuse irradiation reaching a horizontal surface  
377  $H_{dh}$  [J/m<sup>2</sup>], while  $R$  is the percentage of solar radiation that hits the considered surface, which  
378 consists of the incident direct radiation ( $R_{dir}$ ), the incident diffuse radiation ( $R_{diff}$ ) and the radiation  
379 reflected from the ground ( $R_{refl}$ ) depending on the ground albedo  $\rho$  [rad]. When  $R$  is lower than 1,  
380 more radiation is captured by horizontal surfaces than through inclined ones.

381 The available solar irradiation and irradiance are here examined in the general case of horizontal  
382 surfaces, while the inclination of the PV panels is optimized in Sub-section 4.3.

383 From the integration of  $H_h$  over the years, a yearly average solar irradiation of 6900 MJ/m<sup>2</sup> is  
384 obtained for horizontal surfaces.

385 The average hourly irradiance on a unit horizontal surface  $PH$  is therefore 219 W/m<sup>2</sup> on a 24-hours  
386 period and 404 W/m<sup>2</sup> if only sunlight hours are considered. A good yearly stability of irradiance is  
387 observed in the time span of 20 years (Figure 10): little variation of  $PH$  is registered throughout the  
388 two decades and no climate change effect is noticeable (Standard Deviation of 1.08% for both  
389 series).

390 The seasonality of solar irradiance is shown in Figure 11. As expected, full-day data show seasonal  
391 peaks in Spring and Summer, with an average irradiance of 278 and 263 W/m<sup>2</sup> respectively;  
392 conversely, Autumn and Winter present the minimum figures (153 and 180 W/m<sup>2</sup> respectively). The  
393 variations of seasonal mean values over the examined 20 years are minimal: the maximum  
394 percentage difference from the average seasonal value is observed during Autumn (3%). The

395 stability of both annual and seasonal average irradiance values allows for the selection of 2016 as a  
396 reference year, in line with the wave power analysis. In particular, in 2016  $PH$  is  $232 \text{ W/m}^2$  on a 24-  
397 hours period and  $429 \text{ W/m}^2$  considering daylight hours only.

398

406

407

### 4.3 Solar energy harvesting

408

At present, photovoltaic systems are a well-developed technology in all their fixed configurations (roof tops, grounded, over canals, in offshore platforms), presenting a wide variety of materials, radiation-tracking designs, connecting modes, cooling systems (Khare, 2020).

411

Solar irradiation is differently valorised depending on the technology employed and on the exposure and inclination of the panels (see Sub-section 4.2, Eq.2). Fixed-oriented panels were selected for the present application and the exposure angles of the modules were optimised in order to maximise the annual irradiation,  $H_{year}$ , for the selected reference year 2016. According to UNI 8477 (UNI Standards, 1983) the optimum figures obtained for Azimuth and Inclination angles are respectively  $0^\circ$  (South exposition) and  $23^\circ$  with respect to the horizontal, leading to an increase of the average irradiance  $PH$  in the reference year 2016 up to  $244 \text{ W/m}^2$  on a 24-hours period and  $450 \text{ W/m}^2$  considering the daylight hours only.

419

A medium-class panel was selected for the present application. Its main characteristics are reported in Table 7.

421

422 Table 7. Technical characteristics of the selected commercial PV panel (Canadian Solar, 2020).  $W_p$   
 423 is the peak power, i.e. the maximum power produced by the panel.

Class of performance	Model name	Type	$\eta_{PV}$ [%]	$W_p/A$ [W/m <sup>2</sup> ]	$W_p$ [W]	Weight [kg]	Cost [Euro]
Medium	CanadianSolar CS6K 270P	Poly-crystalline	16.8	164.9	270	18.2	170

424

425 The average hourly electric power produced in the  $n$ -th hour  $P_{el,FV,n}$  [W] was derived from Eq. 3,  
 426 according to the procedure proposed by UNI TS 11300-4 (Design of photovoltaic plants):

$$P_{el,FV,n} = \frac{PH_n}{I_{ref}} A_{PV} \eta_{PV} f_{PV} \quad \text{Eq. 3}$$

427 where  $PH_n$  is the irradiance in the  $n$ -th hour [W/m<sup>2</sup>];  $I_{ref}$  is the reference instantaneous irradiance  
 428 equal to 1 kW/m<sup>2</sup>;  $A_{PV}$  [m<sup>2</sup>] is the total area of the capturing surface;  $\eta_{PV}$  is the nominal efficiency  
 429 considering the electric power production of the module with an instantaneous solar irradiance of  
 430 1 kW/m<sup>2</sup> at 25 °C (STC);  $f_{PV}$  is the system efficiency factor, also known as relative efficiency,  
 431 considering the DC/AC conversion system, the irradiation variability and the operative temperature  
 432 of the modules.

433 The seasonal averages of hourly electric power production for the selected PV panel and for the  
 434 reference year 2016 are reported in Table 8. The seasonal variability of  $P_{el,FV,n}$  is more pronounced  
 435 than the seasonal values for the solar irradiance (reported in Sub-section 4.2), as the relative  
 436 efficiency negatively affects the performance in periods with reduced  $PH$  levels. On the contrary,  
 437 Spring and Summer present the maximum irradiance which boosts  $f_{PV}$  and, consequently,  $P_{el,FV,n}$ ,  
 438 overcoming the negative effect due to the increased module temperature.

439

440 Table 8. Seasonal averages and maxima for the hourly electric power  $P_{el,FV,n}$  (W/m<sup>2</sup>) produced by  
 441 the selected medium-class panel in the reference year 2016.

	$P_{el,FV,n}$ - hourly average on full day	$P_{el,FV,n}$ - hourly average on daylight	Maximum $P_{el,FV,n}$
<b>Spring</b>	40	74	149
<b>Summer</b>	50	74	178
<b>Autumn</b>	30	69	168
<b>Winter</b>	26	58	103

442

443 The monthly power for the selected PV modules is shown in Figure 12. All over the year 2016, the  
444 solar irradiation could have led to the production of 320.7 kWh/m<sup>2</sup> with the monthly trend shown  
445 in Figure 13, where the gathered energy from the selected medium-performance PV system is  
446 presented together with the average monthly system efficiencies.

447

448

449 Figure 12. Monthly averages for the electric power ( $P_{ei}$ ) produced from the selected PV panel  
450 during the reference year 2016 (in black whole day averages; in grey, daylight averages).

451

452

453 Figure 13. Comparison between the available solar irradiation and the energy produced per unit  
 454 area by the selected medium-class panel in Tenerife in 2016. In the secondary axis, the efficiency  
 455 of the PV panel ( $\eta_{PV}$ ) is reported.

456

## 457 5. Design of the hybrid plant

458 This Section considers the use of wave and solar energy to supply a desalination facility. The  
 459 characteristics of the desalination plant are defined in Sub-section 5.1. The additional components  
 460 of the power supply system are reported in Sub-section 5.2. The features of the optimal mixing are  
 461 identified in Sub-section 5.3.

### 462 5.1 Sizing of the onshore desalinization plant

463 The municipal marine water desalination plant of Santa Cruz de Tenerife, close to both the WEC and  
 464 the solar plant potential installations, has a total capacity of 28000 m<sup>3</sup>/day (EuropaPress, 2019),  
 465 covering only the 67% of the water demand of Santa Cruz. In the present study, the combined RES  
 466 installation is supposed to provide the power supply required by the enlargement of this plant, that  
 467 would satisfy the entire water demand of the city, i.e. additional 14200 m<sup>3</sup>/day of desalinated water.  
 468 Furthermore, taking into account the population growth and the tourism increase in the last two  
 469 decades (CityPopulation, 2020), the capacity of the RES-driven plant expansion is conservatively

470 increased to 16000 m<sup>3</sup>/day. Considering an average water consumption of 0.16 m<sup>3</sup>/day per-capita  
471 (Rosales-Asensio et al., 2020), the plant expansion would daily provide the water supply to 100'000  
472 inhabitants, equivalent to almost half of Santa Cruz current population.

473 The selected desalination technology for the plant expansion is reverse osmosis (RO), due to its  
474 modularity and energetic convenience (Schallenberg-Rodríguez, et al. 2014). The consumption of a  
475 RO desalination plant is approximately 3 kWh/m<sup>3</sup> in recent applications (Rosales-Asensio et al.,  
476 2020).

477 Considering the selected capacity, the energy consumption for RO technology and the typical  
478 operating period of a desalination plant of 350 days/year (Rosales-Asensio et al., 2020), the annual  
479 consumption of the plant is 16.8 GWh/year, while the power threshold to be hourly satisfied by the  
480 integrated RES installation is 2 MW.

## 481 **5.2 Components of the power supply system**

482 In order to meet the energy requirements of the RO desalination plant in every condition, at least  
483 the following components have also to be installed in combination with the RES integrated system  
484 (Zanuttigh et al., 2021): an energy storage system; a generator set; a dummy load. Specifically,  
485 battery modules can be used for peak shaving, with the benefit of storing energy for the partial  
486 valley filling (Fathima and Palanisamy, 2018), whereas a fuel back-up system can assure the constant  
487 power threshold supply in every RES production condition, including the plant transients and start-  
488 ups (Verdolini et al., 2018). A dummy load, in the form of an electric resistance pack, should also be  
489 included to dissipate the power exceedance and stabilize the power performance of the integrated  
490 system (Zanuttigh et al., 2021). The detailed design of the electrical power system is out of the scope  
491 of this paper (the interested reader can refer to Zanuttigh et al., 2021), therefore, after focusing on  
492 the RES integration, only a rough sizing of the back-up system will follow. In particular, a low-duty  
493 simple-cycle gas turbine will be considered, due to its high flexibility and its high speed in the  
494 transients for power modulation (Gonzalez-Salazar et al., 2018).

## 495 **5.3 Assessment of the RES optimal mixing**

496 The main objective of this Section is the selection of most effective combination of the examined  
497 RES. The optimal RES mix is hereby designed to maximise the time during which the desalination  
498 duties are satisfied by RES only (indicated as  $t_{RES}$  hereinafter), given as a percentage with respect to

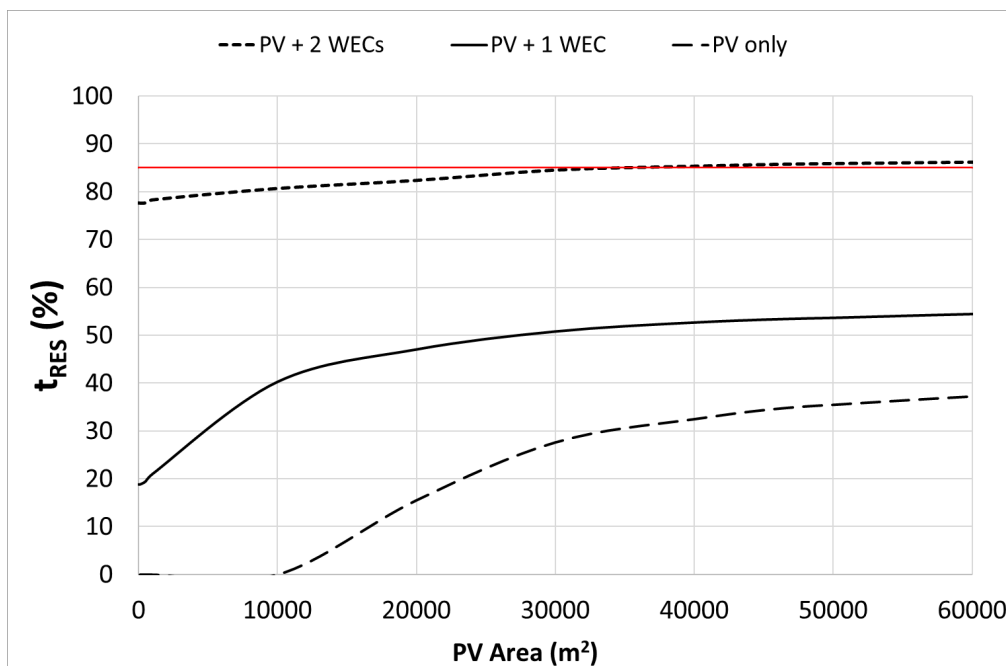

499 the total number of hours in a year. Simulations of possible mixing were performed by varying the  
500 number of wave energy converters as well as the available area for PV panels.

501 The RES functioning time is plotted as a function of the PV-panels area and of the number of WECs  
502 in Figure 14.

503 Once the power target is set, the number of WECs mainly drives  $t_{RES}$ , given their long operation time  
504 even as single resource. The solar park extends the power generation when the WECs are not  
505 operating and contributes to easily achieve the maximum  $t_{RES}$ , thanks to its modularity.

506 Specifically, a single WEC combined with the maximum considered PV-panels area would satisfy the  
507 power request for the 56% of the year only, while the installation of 2 WECs without PV-panels  
508 would increase  $t_{RES}$  to 77%. In this latter case, the combination of 2 WECs with the maximum area  
509 of the PV-panels boosts  $t_{RES}$  towards the asymptotic value of 88%. A good compromise is reached  
510 with 2 WECs and a PV-panels area between 30'000 and 40'000 m<sup>2</sup>, assuring  $t_{RES} = 85\%$ . Thus, the  
511 back-up system would be needed for the 15% of the plant operating time only.

512

513

514 Figure 14. RES functioning time ( $t_{RES}$ ) of the integrated system with variation of PV area and WECs  
515 number for a 2 MW desalination plant.

516

517 In summary, the optimal RES mixing is obtained by means of 2 WECs and a PV-panels area of 35'000  
518 m<sup>2</sup>. This combination (Figure 15):

- 519 • gives a high value of  $t_{RES}$ , equal to 85% (i.e. plant operating for the 85% of the year) and  
520 therefore reduces to 15% the Lack of Supply time  $t_{LS}$ , i.e. the percentage of production time  
521 in which the energy request is not satisfied by RES;
- 522 • ensures the Simultaneous Operation of the two RES plants for the 49% of  $t_{RES}$  (i.e. the 42%  
523 of the year); during this time,  $t_{SO}$  hereinafter, there is a good balance of the contribution of  
524 the two RES, because the WECs and the PV-panels contribute for the 59% and 41%  
525 respectively to the energy production during  $t_{SO}$ ;
- 526 • covers the energy needs during Non-Simultaneous Operation  $t_{NSO}$  (i.e. the remaining 51% of  
527  $t_{RES}$  and therefore the 43% of the year) mostly by WECs (91% of  $t_{NSO}$ ).

528 The main parameters and the production of the single RES installations and of the integrated RES  
529 plant are compared in Table 9.

530 As mentioned above, a back-up system is also introduced to cover  $t_{LS}$  (see Sub-section 5.2). The main  
531 operating parameters are reported in Table 10, where the nominal power is the maximum power  
532 requested in the present case study and the annual energy is the electrical energy to be produced  
533 by means of Natural Gas (NG) combustion. An average conversion performance of 35 % is  
534 considered (Ipieca, 2014) for the economic analysis in the next Section 6.

535 This procedure for optimal RES mixing is not site-specific and can be applied to combine different  
536 RES and to different loads. It requires as inputs:

- 537 • the hourly series of available power from RES;
- 538 • the production curve of the selected devices;
- 539 • the hourly power supply required by the additional activity or the characteristics of the  
540 connection to the power grid.

541 In the present application, a constant power threshold was assumed for the RO desalination plant.  
542 However, in many practical applications (e.g. fish farming or microalgae production), the energy  
543 requirements can be variable at different timescales: hourly, daily, or seasonally. Even in this case,  
544 being the criterion of the maximization of RES functioning time generally valid, the proposed  
545 methodology is applicable, as long as the variability of the energy demand is also known at hourly

546 level. Finally, all the energy losses were neglected, in particular the ones due to wave energy transfer  
 547 to shore.

548

549

550 Figure 15. Simultaneous ( $t_{SO}$ ) and Non-Simultaneous ( $t_{NSO} = t_{WEC} + t_{PV}$ , being  $t_{WEC}$  and  $t_{PV}$  respectively the  
 551 operating time of WECs and of PV panels) operating times of the integrated plant over the year. Total  
 552 year =  $t_{LS} + t_{RES}$ ;  $t_{RES} = t_{SO} + t_{NSO} = t_{SO} + t_{WEC} + t_{PV}$ , where  $t_{RES}$  and  $t_{LS}$  are respectively the RES total operating  
 553 time and the residual time of the year.

554

555 Table 9. Operating parameters of the integrated RES installation compared with the single RES  
 556 installations supplying a 2MW desalination capacity.

	<b>Wave Farm</b> (2 WECs)	<b>Solar Park</b> (35'000 m <sup>2</sup> )	<b>Integrated RES</b>
$t_{LS}$ %	17.2	69.7	15
$t_{RES}$ %	82.8	30.3	85
Nominal Power [kW]	11'900	5'770	17'670
Yearly Average Power [kW]	3'012	1'276	4'288
Yearly Energy Produced [GWh]	26.4	11.22	37.6
Energy of the peaks [GWh]	11.6	4.39	21.9
Energy of the valleys [GWh]	2.8	10.74	1.8
Max Power Missing [kW]	2'000	2'000	2'000
Max Surplus Power [kW]	9'800	4'235	12'984

557

558

559 Table 10. Back-up system performance and operating parameters.

Parameter	Value
Nominal Power (MW)	2
Annual Energy requested (MWh/y)	1818
EFLH - Equivalent Full Load Hours (h/y)	909
Average efficiency – based on LHV (%)	35
Annual Input Fuel Energy – based on HHV (MWh/y)	5771

560

## 561 6. Economics of the hybrid plant

562 The aim of this Section is to assess the economic performance of the hybrid plant. The economic  
 563 indicators considered in the analysis are defined in Sub-section 6.1. Costs of solar and wave energy  
 564 installations and of the backup system are evaluated in Sub-sections 6.2, 6.3 and 6.4 respectively.  
 565 The economic balance is reported in Sub-section 6.5.

### 566 6.1 Economic indicators

567 The economic assessment of the integration of wave and solar energy is carried out for the typical  
 568 year 2016 by assuming the following economic indicators: the Levelized Cost of Energy (*LCOE*), the  
 569 Net Present Value (*NPV*) and the Payback Period (*PBP*).

570 The *LCOE* enables the direct comparison among energies derived from different sources and it  
 571 includes the lifetime of each installation (Segurado, Costa and Duić, 2018). The *LCOE* is determined  
 572 as follows:

$$LCOE = \frac{I_0 + \sum_{t=0}^n \frac{F_t + V_t}{(1+r)^t}}{\sum_{t=0}^n \frac{E_t}{(1+r)^t}} \quad \text{Eq. 4}$$

573 where  $r$  is the discount rate over the  $n$  years of the project, which takes into account the variation  
 574 of money value in time;  $I_0$  represents the capital expenditures (CAPEX), i.e. the initial investment  
 575 costs at  $t=0$ ; the sum of  $F_t$  and  $V_t$  (the fixed and variable operating costs respectively) represent the  
 576 operational expenditures (OPEX), i.e. the annual Operation and Maintenance (O&M) costs;  $E_t$  is the  
 577 energy produced by the plant in the  $t$ -th period.

578 The *NPV* and the *PBP* are calculated according to Eqs. 5 and 6 respectively, (Lauer, 2008). The *NPV*  
 579 allows the estimation of the actual value generated by the investment during the considered

580 lifetime. It consists of the sum of all the discounted cash flows ( $CF_t$ ) of the  $t$ -th year (i.e. the  
581 difference between annual revenue and OPEX) minus the value of the CAPEX, i.e. the initial  
582 investment cost ( $I_0$ ):

$$NPV = \sum_{t=1}^n \frac{CF_t}{(1+r)^t} - I_0 \quad \text{Eq. 5}$$

583 The  $NPV$  therefore represents the Cumulated Cash Flow (CCF) actualized by applying the factor  $r$ .

584 Otherwise, the  $PBP$  indicates the time at which the company starts getting profits according to  
585 undiscounted  $CFs$ , i.e., the time at which the undiscounted cash flow equals the initial investment:

$$PBP = \{t | \sum_{t=1}^n CF_t = I_0\} \quad \text{Eq. 6}$$

586 No discount rate is considered for the  $CFs$  in the  $PBP$  calculation, providing more optimistic results  
587 than the  $NPV$  calculation.

588 In Sub-sections 6.2 and 6.3, the  $LCOE$  is determined for solar and wave energy respectively, to allow  
589 a direct comparison with the typical values of the two sources, while the  $PBP$  and the  $NPV$  for the  
590 hybrid system are reported in Sub-section 6.5.

## 591 **6.2 Levelized Cost of Solar Energy**

592 Table 11 reports the parameters and the unitary costs used for the economic evaluations of the  
593 solar plant considered. The system losses include those due to Balance of System ( $BOS$ ) devices, i.e.  
594 inverters, DC cables and AC cables, and those due to dust, snow and other deposits potentially  
595 covering the capturing surfaces (Photovoltaic-software, 2019). The degradation rate over  
596 production considers the natural performance decay of the PV cells over the years (Photovoltaic-  
597 software, 2019).

598 The  $BOS$  costs include the initial labour expenses for the infrastructure, for the support and  
599 installation of PV modules, for the modules DC cabling, for the setting and purchase of all the  
600 required electricity devices for transformation and grid connection.

601 Operation and Management (O&M) annual expenses include the replacement of modules, inverters  
602 and components, the module cleaning and vegetation management, system inspection &  
603 monitoring, operation administration costs (Reuters Events-Renewables, 2019).

604 Overheads are estimated to be 20% of the sum of the CAPEX and of the OPEX in accordance with  
 605 the common practice of projects financial analysis (Culson and Richardson, 2017).

606 The values of the CAPEX and OPEX for solar facilities strongly depend on the installed capacity, being  
 607 the costs of land purchase, of the modules and of all the needed devices for power transmission  
 608 proportional to the total number of the installed panels. The CAPEX and the OPEX of the considered  
 609 solar plant amount to 6 M€ and 63 k€/year respectively. The LCOE over the 30-years lifetime is equal  
 610 to approximately 44 €/MWh, that increases to 54 €/MWh for a 20-years project. Both results fall  
 611 within the reported range for the PV technology power generation in Europe (Kost *et al.*, 2018;  
 612 Jäger-Waldau, 2019; Margolis, Feldman and Boff, 2020).

613

614 Table 11. Parameters and unitary costs considered for the economic assessment of the solar farm.

Parameter		Value	Reference
Land needed for installation (m <sup>2</sup> )		35'000	Present work
Number of reference PV panels		21'376	Present work
Considered lifetime (y)		30	(Fu, et al. 2018)
Discount rate for solar farms (%)		4	(Guaita-Pradas and Blasco-Ruiz, 2020)
System losses on generation (%)		15	(Photovoltaic-software, 2019)
Degradation rate over production (%)		0.5	(Four Peaks Technologies, 2019)
Cost item		Value	Reference
Land in Tenerife (€/m <sup>2</sup> )		5.9	(Access to land, 2013)
Modules (€/panel)		170	(Canadian Solar, 2020)
Inverters (€/kWp)		42	(Agora Energiewende, 2015)
BOS costs	Infrastructure (€/kWp)	40	(Agora Energiewende, 2015)
	Mounting (€/kWp)	75	(Agora Energiewende, 2015)
	Installation (€/kWp)	50	(Agora Energiewende, 2015)
	DC cabling (€/kWp)	50	(Agora Energiewende, 2015)
	Transformers, switchgears, planning, documentation) (€/kWp)	60	(Agora Energiewende, 2015)
	Grid Connection (€/kWp)	60	(Agora Energiewende, 2015)
O&M yearly costs for fixed-tilt panels (€/kW/y)		11	(Reuters Events-Renewables, 2019)
Overhead on CAPEX + OPEX (%)		20	(Culson and Richardson, 2017)

### 615 6.3 Levelized Cost of Wave Energy

616 With regard to the feasibility study for the WD installation, reference is made to the COE calculation  
 617 tool for wave energy converters developed by Fernandez-Chozas et al. (2014). In the present study, this  
 618 tool is used to make a comparison between the installation of a single and a couple of WDs.

619

620 Table 12 shows all the tool required inputs, besides the WEC power matrix (Table 5) and the wave  
621 climate (Table 2). The assumptions about the WEC performance characteristics and the specific cost  
622 items are here summarised.

- 623 • The mooring weight is up-scaled from Sorensen et al. (2015).
- 624 • The default values are adopted for the power take-off (PTO) and for the generator efficiencies,  
625 while the WEC availability and the WEC's own consumption are assumed to be 95% and 10 kW  
626 respectively (Frigaard et al., 2016).
- 627 • As for the structure costs, the percentages of different materials with respect to the total structure  
628 weight and the costs related to the access system and machine housing are derived from Sorensen  
629 et al. (2015).
- 630 • The default values are adopted for the prices per ton of material and for the cost of development,  
631 of installation, of the electrical connection and of the PTO. In particular, the total suggested price  
632 of the power take-off system is cautiously considered to be proportional to the nominal power and  
633 results to be the most important cost item.
- 634 • The suggested values for contingencies, operation and maintenance costs per year and site lease  
635 and insurance costs per year are assumed.

636 The resulting annual electricity production of one WD in Table 12 is slightly lower than the one reported  
637 in Table 6, due to the necessary simplification of the climate matrix in the tool and to the efficiencies  
638 considered. The resulting CAPEX and OPEX are about 33 M€ and 2.4 M€/y respectively for the  
639 installation of a single WD.

640 In the case of two WDs, the following assumptions are made.

- 641 • The dimensions, the weights and the power are doubled, while WEC performance remain the  
642 same. Therefore, the annual production and the costs of the structure, of the moorings, of the PTO  
643 system and of the electrical connection result to be double.
- 644 • The cost of installation, including assembly and transport, is in this case doubled, while the  
645 expenditures relative to development, access system and platform and machine housing are  
646 supposed to be the same, i.e. a single substation is supposed to serve both WDs and the  
647 maintenance operation are supposed to take place at the same time.
- 648 • The contingencies, operation and maintenance costs per year and site lease and insurance costs  
649 per year are supposed to be the same as for one single WD.

650

651 The CAPEX for two WDs is less than twice the CAPEX previously estimated for one WD (64.5 M€),  
652 while the OPEX is the same, leading to a decrease of the LCOE. Actually, assuming a discount rate of  
653 4%, the LCOE equals respectively 357 €/MWh for one WD and 261 €/MWh for two WDs in 20 years.  
654 Both values fall within the current range 250-600 €/MWh of LCOE of WECs reported by Fernandez-  
655 Chozas et al. (2014) and are indeed much closer to the lower limit.

656 Table 12. Application of the COE tool – WEC features, performance and costs

Number of WECs	1	2
<b>Project data</b>		
Project lifetime (years)	20	20
Development phase	4	4
<b>WEC features</b>		
Main dimension (m)	260	520
Secondary dimension (m)	150	300
Weight - structure (ton)	22'000	44'000
- Concrete (ton)	21'830.77	43'661.54
- Steel (ton)	169.23	338.46
Weight - mooring (ton)	7'897.44	15'794.87
Rated power (kW)	4'000	8'000
<b>WEC performance</b>		
PTO average efficiency	95%	95%
Generator average efficiency	90%	90%
WEC's own consumption (MWh/y)	87.6	175.2
WEC availability	95%	95%
<b>Annual electricity production (GWh/y)</b>	<b>12.33</b>	<b>24.66</b>
<b>Costs</b>		
Development (default value: 3% CAPEX)	868'223	868'223
Main material (concrete, 200€/ton)	4'366'153	8'732'307
Other material (steel, 3400 €/ton)	575'384	1'150'769
Access system and platform	20'000	20'000

657

#### 658 **6.4 Cost of the back-up system**

659 In Table 13, the cost items considered for the back-up system are reported. Medium values are  
660 assumed for the total CAPEX and for the standard O&M expenses of the back-up system. In addition,  
661 variable costs related to NG consumption are considered according to its current price in Spain.

662 Table 13. Economic parameters considered for the back-up system (cost items and prices).

Parameter	Value	Reference
CAPEX – Back-up system (€/kWp)	514	(U.S. Energy Information Administration, 2018)
O&M costs - Gas turbine (€/MWel/y)	0.3	(WADE, 2020)
NG price for businesses – Spain (€/kWht)	0.05	(GlobalPetrolPrices, 2020a)

663

#### 664 **6.5 Economic Balance**

665 The economic balance is set by assuming that the total energy produced by the three sources (i.e.  
666 the wave farm, the solar park and the back-up system) is sold at the average electricity cost for  
667 businesses in Spain, that is 130 €/MWh (GlobalPetrolPrices, 2020b). The total energy is considered  
668 as the sum of the energy produced for the desalination plant and the exceeding energy production  
669 that would have been stored in the battery pack.

670 Extra revenues from the sale of produced wave energy are also considered by including government  
671 incentives for innovative power generation plants. In Spain, wave energy was rewarded with a Feed-  
672 In-Tariff (FIT) amounting to 86 €/MWh in 2014 (Fernandez-Chozas et al., 2014). Presently, this FIT  
673 has been replaced by different incentive schemes which don't comprise wave energy (Jimeno,  
674 2019). Since energy policies are not mandatory and are often amended, different scenarios are  
675 investigated, in presence or absence of incentives on wave energy, as shown in Figure 16.

676 The *PBP* of the hybrid system without incentives is equal to 37 years, based on PV-panels first year  
677 performance, or to 39 years (Figure 16), considering deterioration over time and efficiency decrease  
678 of PV-panels. This *PBP* value is greater than the typical project lifetime of wave and solar installations  
679 but it is still lower than the desalination plant lifetime, which ranges from 20 to 60 years (Papapetrou  
680 et al., 2017). The *PBP* decreases to 17 years in case the Spanish FIT for wave energy is included.

681 The sensitivity of the profitability of the hybrid plant with respect to government incentives is  
682 performed by applying other FIT values provided in other countries (values at 2014). The *CCFs* of the  
683 project are evaluated including the incentives for wave energy of 367 and 600 €/MWh, as  
684 respectively supplied by the United Kingdom and Denmark (Fernández-Chozas et al, 2014). The

685 French support scheme is also applied as it proposes a middle-level remuneration, with an average  
 686 yearly value of 139 €/MWh (Vidalic, 2019). In Figure 17 the *CCFs* are actualized taking into account  
 687 the value of  $r = 4\%$  equal to the case of the single RES plants. The parity point is reached when the  
 688 actualized *CCF* (i.e., the *NPV*) is equal to zero. Although the *PBP* in the no-FIT scenario falls within  
 689 the project lifetime, the *NPV* reveals a non-convenient investment even after 50 years. However, in  
 690 case of FIT application, the *NPV* rises more rapidly with time and the parity point is reached within  
 691 the project lifetime: the more the FIT is increased, the earlier the parity point is achieved, the higher  
 692 the *NPV* results after a given period.

693 The economic assessment shows promising perspectives for future implementations of the hybrid  
 694 plant, which can result rather profitable within 20 years when wave energy is remunerated through  
 695 incentives of at least 140 €/MWh (see Table 14).

696

697

698 Figure 16. Cumulated costs (continuous line) and revenues of the hybrid power plant without  
 699 incentives (dotted line) and with FIT= 86 €/MWh for wave energy (dashed line). Deterioration over  
 700 time of PV-panels was taken into account in the calculations.

## 7. Conclusions

710

711

712

713

714

715

716

This paper started from addressing jointly three key observations: the integration of RES, and particularly of non-contemporaneous RES, may allow to maximise RES production while minimising environmental and economic impacts; most islands are still dependent on expensive fuel imports and are exposed to water scarcity and increasing touristic pressures, requiring the development of desalination plants that are energetically demanding; the local use of RES instead of the connection to the grid may allow to overcome technological and economic barriers for off-shore installations.

717

718

With this aim, the paper analysed the integration of different renewable resources, specifically wave and solar energy, to power a desalination plant in the touristic island of Tenerife.

719 The paper presented an original procedure for the study of RES integration, based on three  
720 consecutive steps. The first one consists in the assessment of the available RES, the second is the  
721 evaluation of the optimal RES mixing and the third one consists in a preliminary economic evaluation  
722 of the hybrid system. This methodology is not site specific and is not dependent neither on the type  
723 of RES and on the devices employed, nor on the characteristics of the external power load.

724 In the first step, the yearly available energy and potential production from waves and sun was  
725 estimated based on literature data. The yearly average wave power in the North-East of Tenerife is  
726 18.54 kW/m, with no significant variation over the examined period 1958-2018. A yearly energy  
727 production of 13.2 GWh/y is obtained by installing a WD device at a depth of about 50 m and at a  
728 distance from shore of about 4 km, in a favourable location for WECs deployment. Contrary to  
729 expectations, the energy production of the WD is almost equally distributed over the different  
730 seasons. The annual average hourly solar irradiance in in the area of Santa Cruz is over 400 W/m<sup>2</sup>,  
731 with peaks in Spring and Summer, and it is stable across the decades both from an annual and a  
732 seasonal point of view. The annual electricity production from a medium-efficiency PV panel is of  
733 320.6 kWh/m<sup>2</sup>/y.

734 In the second step, the optimal RES mixing is determined as the combination of devices that  
735 maximises the time during which the energy needs are satisfied by RES only. The assessment is  
736 carried out based on the hourly RES availability, on the devices hourly producibility and on the  
737 hourly energy requirements of the external activity.

738 In particular, the mixing of wave and solar energy to supply a desalination plant was here designed,  
739 to cover the plant energy requirements by means of RES only for the majority of the time, while  
740 contemporarily minimizing the RES peaks and storage needs. To fill the energy valleys, a proper  
741 back-up system is designed, consisting of a low-duty simple-cycle gas turbine. The combination of  
742 energy generation by two WDs and an area of 35'000 m<sup>2</sup> of PV-panels area reduces to 15% the time  
743 period over which the RESs are insufficient to provide the power supply to the 2MW desalinisation  
744 plant in Tenerife.

745 This optimal mixing criterion can be applied to any RES combination and in any site. Depending on  
746 the application, the variability of energy requirements at different timescales has to be considered.  
747 For a more detailed evaluation, energy losses should also be taken into account.

748 In the third step, a generic framework for a preliminary economic evaluation of the hybrid system  
749 is provided, by identifying the most important economic indicators and by describing a procedure  
750 for the assessment of economic balance. The framework takes into account some key parameters,  
751 such as government incentives, and can support the scenario analysis for a promising development  
752 of such hybrid plants at any location.

753 Specifically, the preliminary economic assessment of the examined integrated RES installation in  
754 Tenerife shows that the LCOE of each resource after 20 years (53.31 €/MWh for solar energy and  
755 261 €/MWh for wave energy) falls within the respective typical ranges which can be found in recent  
756 literature. The pay-back period of the investment for the hybrid plant is of 39 years and may  
757 decrease to less than 20 years in case of government incentives, such as the FIT, that could  
758 significantly increase the confidence towards innovative energy transition projects.

759
