1. Experimental Procedures

1.1 Computational Details

The assignment of the rotational spectrum of (Z)-1,2-ethenediol (hereafter Z-4) was supported by a theoretical simulation relying on computed rotational parameters. A preliminary investigation of the potential energy surface (PES) of the Z-4 system has been carried out using the double-hybrid B2PLYP density functional^{1, 2} (also including the D3 correction for empirical dispersions by Grimme employing the Becke-Johnson damping function^{3, 4}) in conjunction with the aug-cc-pVTZ basis set^{5, 6}. For the energetics, zero-point energy (ZPE) corrections have also been taken into account at the same level of theory within the harmonic approximation. From a bidimensional relaxed scan of the H2O2C2C1 and C2C1O1H1 dihedral angles, two minima (MIN1 and MIN2 in Figure S1) and two transition states (TS1 and TS2) were located on the PES. For each stationary point, the geometry was optimized using a “very tight” criteria, while its nature was ensured by the diagonalization of the corresponding Hessian matrix. MIN1 is the (*syn,anti*) form of Z-4 and corresponds to the global minimum on the PES, while MIN2 is the (*anti,anti*) form lying about 15 kJ mol⁻¹ higher in energy. The two minima are connected via TS2 located 21 kJ mol⁻¹ above MIN1. At the same time, MIN1 tunnels between two equivalent forms that interconvert via TS1, with a barrier height of 10 kJ mol⁻¹.

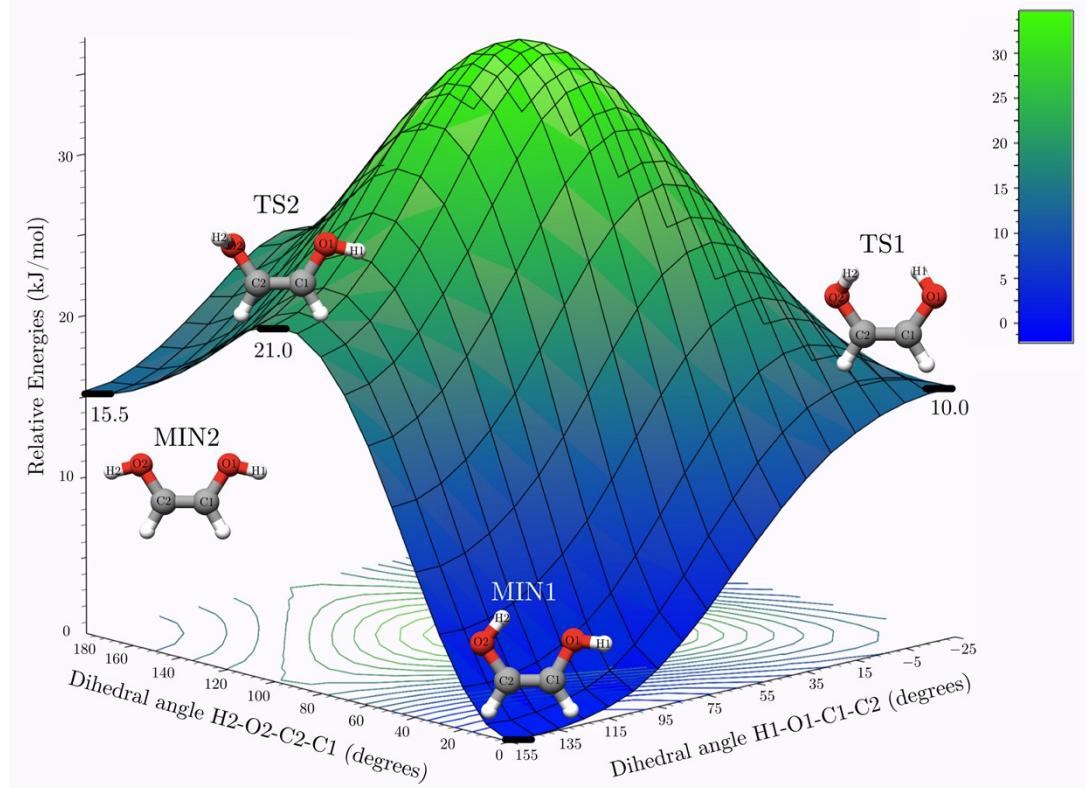

Figure S 1 Portion of the potential energy surface of (Z)-1,2-ethenediol (Z-4) computed at the B2PLYP/aug-cc-pVTZ level of theory.

Assuming that Z-4 is produced in the experimental apparatus following a Boltzmann distribution, MIN2 is too high in energy to be observed. Therefore, only MIN1 was considered for the computational spectroscopic characterization. The equilibrium rotational constants of MIN1 were straightforwardly obtained from the equilibrium structure optimized at the CCSD(T)/CBS+CV level within the so-called “gradient” composite scheme⁷⁻⁹. In this approach, the energy gradient to be minimized consists of three contributions:

1. the HF-SCF energy¹⁰ extrapolated to the complete basis set (CBS) limit employing the three-point expression by Feller¹¹ in combination with the cc-pVnZ basis sets⁵, with $n = T, Q, 5$;

2. the estimate of the CBS limit for the CCSD(T)¹²⁻¹⁴ correlation energy obtained employing the n⁻³ formula by Helgaker et al.¹⁵ and the cc-pVTZ and cc-pVQZ basis sets⁵;
3. the core-valence (CV) contribution calculated as the difference between all-electron and the corresponding frozen-core computation at the CCSD(T)/cc-pCVTZ level^{5, 16}.

The vibrational corrections to the equilibrium rotational constants as well as the vibrationally averaged dipole moment values and the quartic and sextic centrifugal distortion constants have been obtained from anharmonic force field calculations at the fc-MP2/cc-pVTZ level of theory^{5, 17}. All these parameters were finally input in the SPCAT program¹⁸ to simulate the rotational spectrum of Z-4.

In addition, since MIN1 possesses only one H atom out of the molecular plane (HOCC=25°), the barrier to planarity was investigated by performing a rigid scan of the HOCC dihedral angle. The computations, at the B2PLYP-D3BJ/aug-cc-pVTZ level of theory, revealed a barrier to planarity of 0.2 kJ mol⁻¹.

Both the MP2 and CCSD(T) calculations were performed by using the CFOUR package¹⁹, while DFT computations have been carried out with the Gaussian16 suite of program. All the results are collected in Table 1 of the main paper. The B2PLYP-D3BJ/aug-cc-pVTZ geometries of the four stationary points are given in Tables S1-S4.

1.2 Synthesis of the Norbornene Derivative and NMR Spectra

Bis-exo-5-norbornene-2,3-diol (compound **5**, IUPAC name (1*R*,2*R*,3*S*,4*S*)-bicyclo[2.2.1]hept-5-en-2,3-diol) was synthesized as reported by Maier et al.²⁰

Before attempting to record the rotational spectrum of **Z-4**, the pyrolytic route was tested with NMR spectroscopy analysis. To this purpose, about 200 mg of **5** were introduced into a small flask and the latter was connected to the oven heated to 750°C and fitted to a cold finger cooled with liquid nitrogen in a vacuum line (0.1 mbar). Compound **5** heated to about 50°C was slowly introduced into the oven. Cyclopentadiene (**6**), **Z-4**, and a small amount of glycolaldehyde (**2**) were formed and condensed on the cold finger; THF-d₈ (700 µL) was then added. At the end of the reaction, the cold finger was disconnected from the vacuum line, filled with dry nitrogen and the liquid nitrogen was removed with compressed air. The products and the solvent were flowed into an NMR tube attached to the bottom of the cold finger.

Compounds **Z-4** and **2** can be selectively trapped at -80°C in a U-tube placed after the oven, but attempts to re-vaporize **Z-4** have failed. The quality of the vacuum results in a higher **4:2** ratio. ¹H NMR (THF-d₈, 400 MHz, 193 K): δ 5.54 (s, 2H, CH), 6.25 (s brd, 2H, OH). ¹³C NMR (THF-d₈, 100 MHz, 193 K): δ 123.5 (dd, ¹J_{CH} = 182.3 Hz, ²J_{CH} = 17.2 Hz, CH).

1.3 Rotational Spectrum

The rotational spectrum of **Z-4** has been recorded between 80-125 GHz and 240-375 GHz with a frequency-modulation millimeter/submillimetre-wave spectrometer, whose detailed description has been reported elsewhere²¹,²².

Briefly, the spectrometer employs several Gunn diodes working in the W and F bands as primary radiation source. Higher frequencies are obtained by coupling the Gunn diodes with passive frequency multipliers (doublers and triplers in cascade). The frequency and phase stability of the radiation source is provided by a phase-lock-loop which uses a 75 MHz sine wave modulated signal as reference, while the frequency accuracy is ensured by a rubidium atomic clock.

The radiation is fed into a 3 m long glass absorption cell connected to the flash vacuum pyrolysis apparatus at one end and to a pumping system at the other end. The title molecule has been produced by flowing the vapours of the precursor species **5** through a 30 cm long quartz tube heated at 750°C by a tubular furnace. In order to increase its vapour pressure, compound **5** has been maintained at 50°C with the use of a heating tape. The pressure inside the absorption cell has been kept at around 4 μ bar; in these conditions, the transitions of **Z-4** appear as the most intense ones in the spectrum. Signals belonging to **2** and **6** have been observed as well.

The output radiation is then detected by a zero-bias Schottky barrier detector, pre-amplified, and sent to a lock-in amplifier. The lock-in acts as a resistor-capacitor filter and demodulates the signal at twice the modulation frequency, so that the second derivative of the original line shape is actually recorded (2f detection scheme).

The measurement uncertainty on any observed transition is estimated to between 20 and 50 kHz, depending on the attained signal-to-noise ratio of the spectrum, line width, and line contamination.

2. Results and Discussion

The (*syn,anti*) form of (*Z*)-1,2-ethenediol is an asymmetric top rotor close to the prolate limit (asymmetry parameter $\kappa = -0.79$). At the equilibrium, it possesses a permanent electric dipole moment $\mu = 2.27$ D with non-vanishing components along all the three principal inertia axes ($|\mu_a| = 1.96$ D, $|\mu_b| = 0.62$ D, and $|\mu_c| = 0.97$ D).

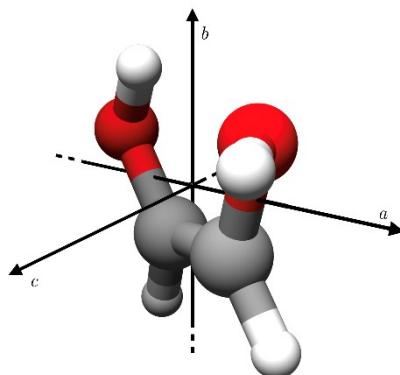

Figure S 2 *Z*-(*syn,anti*)-1,2-ethenediol in its principal inertia system.

Although ab initio calculations suggest a C_1 symmetric equilibrium structure, the tunneling between two equivalent positions of the hydroxy groups experimentally observed indicates that **Z-4** belongs to the $C_2(M)$ permutation-inversion symmetry group. The tunneling motion causes the splitting of each J_{KaKc} rotational energy level into two. The two inversion substates can be conveniently labelled as $v = 0$ and $v = 1$, with the 0 state being more stable by 0.362(4) MHz (see Table 1 of the main text). Since the tunneling motion inverts the sign of μ_a and μ_c , *a*-type ($\Delta K_a = \text{even}$, $\Delta K_c = \text{odd}$) and *c*-type transitions ($\Delta K_a = \text{odd}$, $\Delta K_c = \text{even}$) occur

between the two inversion states. Conversely, *b*-type transitions ($\Delta K_a = \text{odd}$, $\Delta K_c = \text{odd}$) occur within each state. Moreover, since the tunneling motion exchanges two pairs of identical hydrogen nuclei, the intensity of the observed spectral features is governed by spin-statistics effects. In particular, symmetric nuclear spin functions ($I_{\text{TOT}} = 0, 1, 2$) only combine with symmetric rotation-inversion states (identified by $v + K_a + K_c = \text{even}$), while antisymmetric nuclear spin functions ($I_{\text{TOT}} = 1$) only combine with antisymmetric rotation-inversion states ($v + K_a + K_c = \text{odd}$). As a result, each transition is observed as a closely-spaced doublet with an intensity ratio of 10:6. The position of the energy levels has been modelled using a rotational-torsional Watson *S*-reduced Hamiltonian²³ arranged in the RAS (reduced-axis system) formalism²⁴. In this approach, the energy levels manifold is derived by fitting the rotational constants *A*, *B*, and *C* and the energy difference *E** between the two inversion states together with their centrifugal distortion dependencies. In this work, terms up to 8th power of the rotational angular momentum have been included in the Hamiltonian. Furthermore, the interaction between the 0 and 1 states has been taken into account through the *c*-type Coriolis term F_{ab} . In total, 1153 transitions have been recorded up to 375 GHz and analysed in a weighted least-squares procedure with SPFIT¹⁸. More precisely, the dataset includes 578 distinct lines (505 of *a*-type and 73 of *b*-type) and probes rotational levels up to $J = 36$ and $K_a = 26$, thus allowing for the accurate determination of several spectroscopic constants. For example, the rotational constants have been obtained with an average deviation of 0.0016%, while the uncertainty of the quartic centrifugal distortion parameters is around 0.018%. Five higher-order distortion constants (H_1 , H_{JK} , H_{KJ} , h_1 , and L_{KK}) have also been determined, whereas H_K , h_2 , and h_3 have been kept fixed at their computed values.

The energy difference *E** between the two inversion states has been determined at kHz accuracy. The Coriolis coefficient F_{ab} is well constrained (-218±6 MHz) and comparable to that found in ethylene glycol (~ -143 MHz)²⁵. At the end of the fitting procedure, the root-mean-square error of the residuals is 33.1 kHz. The list of all the observed transition frequencies is given at the end of this file.
