34  
35 **Abstract**  
36

37 Mortars containing glass waste as a partial substitution for natural sand have been  
38 formulated. Alkali activated fly ashes have been used as a binder. The selected cullets  
39  
40 are those deriving either from the discarded lamps collection or the fraction of the  
41  
42 selective urban glass collection (about 10 wt% on the whole amount) that, because of its  
43  
44 highly heterogeneous composition, cannot be used in the production of new glass items.  
45  
46 Mechanical properties of the obtained mortars have been investigated as well as their  
47  
48 durability. In details, the reactivity towards alkali silica reactions and sulphates

5  
6 diffusion, as well as the stability to freeze-thaw cycles have been compared to the ones  
7  
8 of unmodified mortars. Both types of waste do not lead to a decrease in the durability of  
9  
10 the obtained materials. The inertness of these cullets towards alkali silica reaction is  
11  
12 quite remarkable since both wastes are highly reactive in Portland cement matrix. This  
13  
14 introduces a possible reuse in the formulation of low-impact renders for these fractions  
15  
16 that presently have no alternatives to landfilling.

## 30 **1. Introduction**

31  
32 Glass recycling is not a closed-loop system. Due to the scanty quality of the urban  
33  
34 collection, to the erratic conferring of many domestic items and to the limits of the  
35  
36 separation that can be performed in sorting plants, around 10% of the overall collected  
37  
38 amount of glass is disposed in landfills [1]. According to the European Waste Catalogue  
39  
40 (EWC) [2], the code (19 12 05) is assigned to this fraction. The composition of this  
41  
42 material is rather heterogeneous. Crystal items (containing at least 25 wt.% of lead  
43  
44 oxide), ceramics (including porcelain), Pyrex (borosilicate glass), light bulbs, neon  
45  
46 tubes, mirrors, television and computer monitors (like cathode ray tubes (CRTs) and  
47  
48 liquid crystal displays (LCDs)) and other inert materials, are wrongly considered to be  
49

65

1  
2  
3  
4  
5  
6 assimilated to packaging glass and consequently delivered in the bottle bank. A further  
7  
8 example of unrecycled glass is that deriving from the separated collection of discarded  
9  
10 lamp cullets. In this case, the presence of a small amount of lead oxide (< 1% wt) again  
11  
12 classify this waste as special ones (European catalogue Code 19 12 05).  
13  
14

15  
16 A possible way to prevent damping is the use of cullet as a substitute of natural sand in  
17  
18 mortars [3-17]. Soda-lime glass recycling in building materials creates many benefits to  
19  
20 the environment and justifies the presence of many researches present in literature.  
21  
22

23 When using a Portland cement matrix, the main problem arising from the presence of  
24  
25 glass cullets is the occurrence of alkali-silica reactions (ASR). Soda-lime glass [18-24],  
26

27 the first composition to be studied, being the more diffused one since it derives from  
28  
29 packaging items, shows a limited reactivity towards alkalis. This partial reactivity  
30  
31 depends on the presence of chromophore ions in the amorphous network, indeed to the  
32  
33 glass colour. For example, flint glass is less reactive than brown and green ones [23].  
34  
35

36  
37 Glass having more complex chemical composition and different origin, especially those  
38  
39 containing heavy metals like lead, barium and strontium, have proved to be extremely  
40  
41 deleterious forming highly expanding reaction products [25-29]. Although the problem  
42  
43 can be prevented by the use of pozzolanic binders as a partial Portland substitution [30-  
44

45  
46 33] or by some surface treatments that can change the glass chemical composition [34-  
47  
48 36], other solutions can prove to be more convenient. In the last years, great attention  
49  
50 has been attracted by alkali activated materials [37-40]. These binders have lower

5  
6 carbon dioxide footprint than Portland cement and can give rise to large environmental  
7  
8 benefits when deriving at least partially from industrial wastes. Moreover, preliminary  
9  
10 researches [41-43] have also underlined how aggregates expanding in Portland cement  
11  
12 mortars can become innocuous with alkali activated binders. In the present research, the  
13  
14 durability of mortars formulated with alkali activated fly ashes and the two different  
15  
16 types of waste glass previously described, i.e. the discarded fraction of the separate  
17  
18 urban collection and separately collected fluorescent lamp are investigated. Both types  
19  
20 of cullet had proved to be extremely reactive towards ASR in Portland matrix  
21  
22 composites [44]. It seemed thus interesting to study their behaviour in a different matrix,  
23  
24 to determine whether this could inhibit alkali silica reactions. Moreover, other durability  
25  
26 aspects, such as the resistance to freeze-thaw cycles and the possible deleterious  
27  
28 reactions triggered by sulphates diffusion on geopolymer binders play an important role  
29  
30 in the future development of these materials. Many researches have been recently  
31  
32 carried out on these subjects [45-49]. Consequently, in this research the effect of these  
33  
34 recycled cullets on the durability of mortars has been studied in presence of these  
35  
36 environmental stresses. An unmodified standard Portland mortar has been tested in the  
37  
38 same conditions for comparison sake.

5  
6 2.1.1 Glass wastes  
7

8 Crashed residuals of separate glass waste collection (that will be defined as Residuals of  
9 Urban Collection, RUB in the subsequent text) were kindly supplied by CoReVe  
10 (Consortium for Glass Recycling, Italy). This is a rather heterogeneous material.  
11  
12 Fragments of ceramics, pebbles, mirrors splinters and light bulbs are mixed with glass  
13 cullet of different colour. Figure 1 shows the morphology of the wastes. The material is  
14 used without any sorting, that is to say, with all its contaminants. Consequently, the  
15 average chemical composition of the material was obtained by insulating a  
16 representative sample of 1 kg, collected by quartering. The sample was remelted at  
17 1450°C in electric oven and quenched at room temperature. A homogeneous glassy  
18 specimen was obtained. Fragments herein obtained were analysed by energy-dispersive  
19 spectrometer EDS (microanalyzer Inca-350, Oxford Instruments) in different areas of its  
20 surfaces. The average chemical composition is reported in Table 1.

8 Normalised silica sand conforming to the EN 196-1 Standard [50] was used. The size  
9 distribution is reported in Figure 2.  
10  
11

12  
13 2.1.3 Binders  
14

15 Fly ashes (Type F), whose chemical composition is reported in Table 1, deriving from  
16 the plant of Torrevaldaliga (Roma, Italy) were used. They have an average dimension  
17 (D50) of 22  $\mu\text{m}$ .  
18  
19

20 Portland cement Type II / AL 42.5 was used (Italcementi, Bergamo, Italy).  
21  
22

23 2.1.4 Activators  
24

25 The sodium silicate solution used was a viscous liquid produced for the cement industry  
26 (Ingessil, Verona, Italy) with a water content of 56 wt%, the  $\text{SiO}_2/\text{Na}_2\text{O}$  oxide  
27 composition ratio of 2.07 and a density of 1.53  $\text{g}/\text{cm}^3$ .  
28  
29

30 An 8 M water solution of sodium hydroxide (reagent grade form Carlo Erba, Milano,  
31 Italy) was used.  
32  
33

34 2.2 Mortars preparation  
35

36 Mortars containing glass wastes (M-RUB and M-LMP in the subsequent text) were  
37 mixed by substituting 20 wt.% of natural siliceous sand. The binder/aggregate (b/a)  
38 ratio was 1.00/3.00. For samples to be submitted to ASR expansion test, a b/a ratio of  
39 1.00/2.25 was used instead. Table 2 reports the mix design of all the investigated  
40 mortars and their relevant denomination, which will be used afterwards in the text. Mix

65

design, that is the ratio between fly ashes, activators and water was performed according to a previous research [39] in order to obtain  $\text{Na}_2\text{O}/\text{SiO}_2$  and  $\text{Na}_2\text{O}/\text{Al}_2\text{O}_3$  ratios of 0.12 and 0.42 respectively. This composition allowed to obtain good mechanical properties. As a reference, M-REF mortar was prepared with 100 wt.% of natural sand. Mixing was performed by first adding sodium hydroxide to the fly ashes and subsequently pouring the silicate in the vessel. After 3 minutes of stirring, glass waste was added to the paste, followed by the natural sand. The whole procedure lasts for 10 mins. In order to provide a benchmark, a mortar with standard composition (water/binder w/b 0.5 and b/a 1.00/3.00) was formulated using a traditional Portland 42.5 Type cement [50] (M-PRT in the subsequent text). Mixing procedures for this mortar followed the instruction of EN 196-1 [50].

Table 2. Composition and labelling of all investigated samples.

Mortar sample	Natural sand (g)	Glass waste (g)	Sodium silicate solution (g)	NaOH 8M solution (g)	H <sub>2</sub> O (g)	Fly ash (g)	Portland cement (g)
M-REF	1350	0	188	38	35	500	-
M-RUB	1080	270	188	38	35	500	-
M-LMP	1080	270	188	38	35	500	-
M-PRT	1350	0	0	0	225	-	450

1  
2  
3  
4  
5  
6 After the mixing process, mortars were cast in a truncated conical mould having a  
7  
8 circular base (100 mm of diameter at the bottom, 70 mm of diameter at the top and 60  
9  
10 mm height, according to EN 1015-3 [51]). The mould was subsequently removed and  
11  
12 the mortar shaken by means of a jolting device. The final dimension (i.e. the diameter)  
13  
14 of the collapsed mortar was measured in two perpendicular directions and the  
15  
16 workability (W) was thus calculated according to Eq. (1)  
17  
18  
19

$$20 \quad W = 100 \times (d_m - d^\circ) / d^\circ \quad (1)$$

21  
22 where  $d_m$  is the average diameter of the two readings and  $d^\circ$  is the lower diameter of the  
23  
24 truncated conical ring, i.e. 100 mm.  
25  
26

27  
28 The mixed mortars were cast in steel moulds to obtain 40 x 40 x 160 mm samples. In  
29  
30 order to partially eliminate entrapped air and ensure an efficient filling of the moulds  
31  
32 mortars were subjected to a defined number of jolts applied by means of a standardized  
33  
34 jolting apparatus. Mortar samples were subsequently demoulded after a 24 h storage at  
35  
36 98 % R.H. and kept at  $20 \pm 1$  °C in sealed polyethylene bags.  
37  
38  
39  
40  
41

## 42 2.3 Instruments and methods

### 43 2.3.1 Density and porosity

44  
45 Mortars density has been determined according to the EN 772-13 Standard [52] at 28  
46  
47 days of curing.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61

1  
2  
3  
4  
5  
6 Porosity was calculated by determining the amount of absorbed cold water at  
7  
8 atmospheric pressure following the EN 772-21 Standard [53] at 28 days of curing.  
9

### 10 11 2.3.2 Expansion test

12  
13 Alkali silica reactivity was evaluated according to the procedure described by ASTM  
14  
15 C1260 [54], i.e. curing the specimens in moisture saturated conditions for 28 days, one  
16  
17 day water curing at 80°C and subsequent storage at 80 °C in a 1 M solution of sodium  
18  
19 hydroxide. The test was performed on three different samples for each of the  
20  
21 investigated compositions.  
22  
23

### 24 25 2.3.3 Mechanical test

26  
27 Mechanical tests (compression) on all samples were performed at room temperature and  
28  
29 R.H. 50 ± 10 % by means of 100 kN Volpert Amsler equipment with a 50 mm/min  
30  
31 displacement rate. The test was repeated on six samples at 28 days of curing.  
32  
33

### 34 35 2.3.4 Sulphates penetration

36  
37 Samples with the standard dimension (40 x 40 x 160 mm) after 28 days of curing were  
38  
39 soaked in a 1M Na<sub>2</sub>SO<sub>4</sub> solution. At scheduled times, the dynamic elastic modulus was  
40  
41 determined by means of a MATEST mod C369 (Treviolo, Italy). Equation (2) was  
42  
43 applied to calculate the modulus value:  
44  
45

$$46 \quad E = \rho \cdot V^2 \quad (2)$$

47  
48 where:

49  
50 V is the measured pulse velocity (m/s) and  $\rho$  is the density expressed in kg/m<sup>3</sup>.  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61

### 2.3.5 Freeze-thaw cycles

Samples having the same geometry and curing as before were submitted to freeze-thaw cycles according to ASTM C666 [55] that is (a) keeping samples at  $-10^{\circ}\text{C}$  (b) subsequent thawing at  $4^{\circ}\text{C}$ . At scheduled times the dynamic elastic modulus was determined according to the previous procedure.

### 2.3.6 Microstructure

Analyses were performed by means of a Quanta (FEI) scanning electron microscope equipped with an EDS X-ray detector. The fractured surfaces to be examined were coated by graphite to ensure electrical conductivity. Accelerating voltage of 20 kV was applied during all measurements.

## 3. Results and discussion

Table 3 reports the workability (expressed according to equation 1) of all the investigated mortars. The addition of both LMP and RUB increases the workability of mortars as compared to the one containing only natural sand. This effect has been already observed in literature for similar cullet additions [21, 43, 56] and has been ascribed to the smoother and less porous surface of the particles that tends to absorb less water than natural sand, thus changing the viscosity of the matrix. The density and the open porosity of the samples are also reported in Table 3. Both parameters remain almost constant as the natural sand is substituted for the wastes. The slight reduction in

1  
2  
3  
4  
5  
6 density of M-RUB and M-LMP samples can be explained by the lower density of the  
7  
8 cullets compared with the one of natural sand. The benchmark mortar (M-PRT) has a  
9  
10 lower workability and a higher porosity.

11  
12  
13 Table 3. Physical properties of the investigated mortars.

14  
15

Sample	M-REF	M-LMP	M-RUB	M-PRT
Workability (%)	59.1 ± 0.6	69.6 ± 0.9	69.0 ± 0.4	41.3 ± 0.8
Density (g/cm <sup>3</sup> )	2.11	2.07	2.03	2.11

25  
26

27  
28 Figure 3 reports the expansion (1M NaOH solution, 80°C) of mortar samples  
29  
30 formulated with and without the wastes. The acceptable limit, defined by the ASTM  
31  
32 C1260 Standard [54], as the one ensuring an innocuous behaviour of the aggregates is  
33  
34 of 0.1%. Although this limit has been formulated for traditional Portland cement  
35  
36 composites, the same value will be used for alkali activated composites. Indeed, all the  
37  
38 investigated mortars fall below this limit after the prescribed curing time of 14 days.

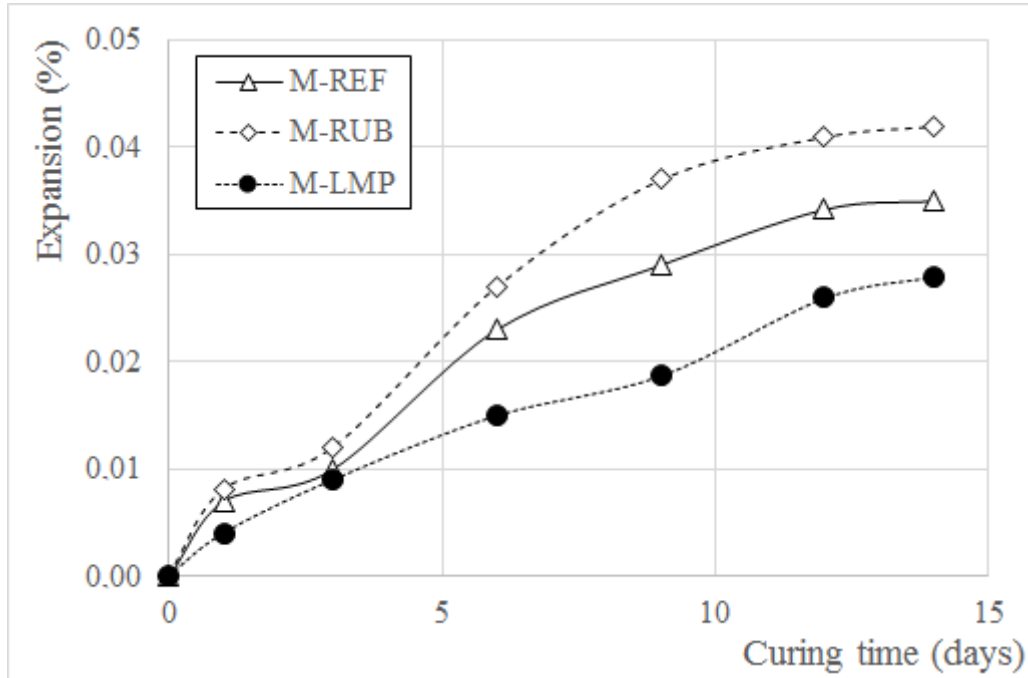

Fig. 3. Expansion at 80°C.

Figure 4 shows an example of the morphology of LMP cullets on the fractured surface of M-LMP mortar treated at 80°C after 14 days of curing. The transition zone between the aggregate surface (white arrow) and the matrix shows no expanding products and appears as unreacted. The morphology of RUB cullets in the same conditions is reported in Figure 5 for M-RUB mortar, disclosing a similar aspect.

3  
4  
5  
6 Figure 6 reports the expansion of mortars cured at 38°C. As recorded before, all  
7  
8 samples behave similarly and a quite limited expansion is detected even at the longest  
9  
10 curing time. SEM observations (Figures 7 and 8) disclose the non-reactive behaviour of  
11  
12 both LMP and RUB cullets respectively, showing unreacted surfaces. These results  
13  
14 confirm that alkali activated fly ash systems are quite efficient in preventing ASR as  
15  
16 found elsewhere [41, 42]. On the contrary, Portland cement mortars had previously  
17  
18 shown strong expansion of both type of cullets [44].

Fig.7. Unreacted LMP cullet at 60 days of curing (38 °C) for M-LMP mortar.

Fig. 8. Unreacted RUB cullet at 60 days of curing (38°C) for M-RUB mortar.

The average compressive strength of mortars after the different curing conditions (28 days at room temperature, end of the accelerated test for alkali reactivity at 80 °C and

1  
2  
3  
4  
5  
6 38 °C) is reported in Figure 9. It should be noted that the alkali activated binder  
7  
8 provides, in all cases, values comparable to the Portland mortar after 28 days of curing  
9  
10 at room temperature. M-RUB and M-REF samples show comparable values of strength,  
11  
12 while M-LMP samples have slightly higher values (about 10% ). Mechanical results  
13  
14 obtained after the accelerated ASR tests both at 38 and 80 °C show increased values  
15  
16 than those obtained after 28 day of curing. This confirms that no expanding reactions  
17  
18 take place during the tests since the mechanical properties are not compromised.  
19  
20 Moreover, the higher temperatures and, in the case of the 38 °C the longer curing times,  
21  
22 favour the development of the alkali activated network. The higher strength values  
23  
24 found in M-LMP samples, especially cured for 28 days at 20°C and for 14 days at 80 °C  
25  
26 in a 1M NaOH, is probably deriving from the sharp flat morphology of the cullets that  
27  
28 provides higher mechanical interaction with the matrix than that of the roundish sand  
29  
30 particles. A further contribution could arise from the increased alkalinity present at the  
31  
32 interphase between matrix and cullet. The partial glass dissolution, taking place in the  
33  
34 alkaline environment, as recently found in other researches [57], can influence the  
35  
36 chemistry of the reactions involved in the matrix development. The extent of glass  
37  
38 dissolution in this system should however be limited, since no clear evidence of  
39  
40 dissolution could be detected from SEM observations.

Fig. 9. Mechanical properties of samples in different curing conditions.

(\*) Portland samples not reported since showing expanding behaviour

As to what concerns the effect of sulphates diffusion, in Figure 10 the value of the elastic modulus determined through the pulse velocity (Equation 2) is reported.

Fig. 10. Plot of the dynamic elastic modulus vs time of mortars in sulphates solution.

All samples formulated with the alkali activated matrix show an increase in the elastic modulus during the first stages, reaching an asymptotic value at the longest curing times. This trend is not depending on the aggregate type and it is thus depending only on the matrix strength. Mortar formulated with Portland cement (M-PRT) shows a clear decrease after about 120 days of exposure. In order to confirm the induced damage in these mortars, SEM observations were carried out collecting samples at the longest curing times (180 days). Figure 11(a) shows the ettringite crystals on M-PRT mortars and 11(b) the microstructure of M-RUB sample, similar to M-LMP and M-REF, for sake of comparison.

Fig. 11. (a) ettringite samples in M-PRT sample (b) alkali activated matrix of M-RUB sample.

Figure 12 reports the trend of the elastic modulus of all the investigated mortars submitted to freeze-thaw cycles. The values of the modulus show a slight decrease as the number of cycles increases in all the samples. The extent of this progressive decrease is comparable in all formulations ranging from a 9.4 % in M-REF to a 6.1 % in

1  
2  
3  
4  
5  
6 M-RUB sample of the initial value (Portland mortar shows an 8% reduction, M-LMP an  
7  
8 8.6%). Alkali activated materials prove thus to perform similarly to traditional standard  
9  
10 Portland composites. Moreover, the use of both wastes does not compromise the  
11  
12 durability.  
13  
14  
15  
16  
17

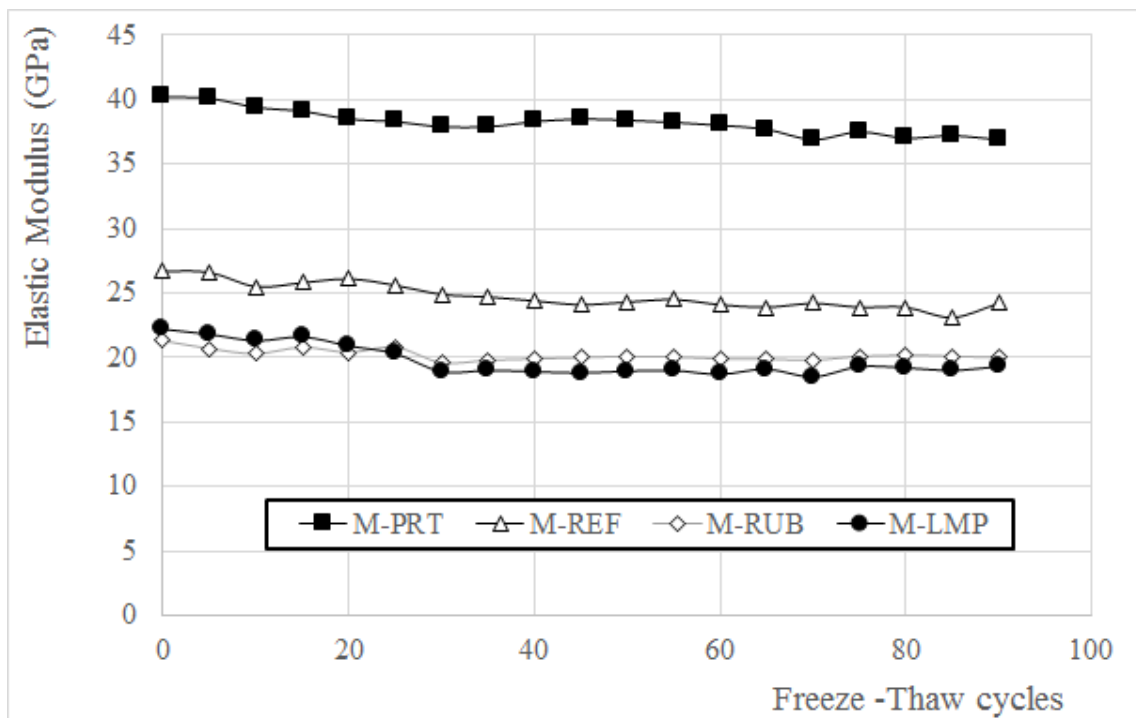

Fig. 12. Elastic modulus vs freeze-thaw cycles.

47  
48 Up to now, alkali activated materials are not usually applied in structural application  
49  
50 mainly due to the absence of *ad-hoc* standards. Their use can thus be limited to low  
51  
52 demanding application such as renders, conduits, sewer pipes or drainage channels. In  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5  
6 this context, the low-impact environmental characteristics of the investigated materials  
7  
8 as well as their increased sulphates durability compared to traditional Portland cement  
9  
10 mortars, offer an important advantage. It is thus possible to prevent cullet damping and  
11  
12 reduce natural sand extraction, both factors reducing also the overall final cost of the  
13  
14 composite.  
15  
16  
17  
18  
19  
20

#### 21 **4. Conclusions**

22  
23 Alkali activated mortars obtained from the alkali activation of fly ashes and containing a  
24  
25 20 wt% amount of waste glass as natural aggregate substitution have been formulated.  
26  
27 Their rheological properties in the fresh state are improved when compared to the  
28  
29 unmodified material. The microstructure of the mortars in terms of density and open  
30  
31 porosity is almost unchanged as well as their mechanical properties.  
32  
33

34  
35 Accelerated tests at 80 and 38°C underline an inert behaviour of the wastes towards  
36  
37 expansive, deleterious reactions. Modified mortars show the same stability towards  
38  
39 freeze-thaw cycles and sulphates diffusion as the unmodified ones. All the alkali  
40  
41 activated composites are more stable than traditional Portland ones that are affected, at  
42  
43 the same curing time, by Delayed Ettringite Formation (DEF) reaction and show the  
44  
45 same stability towards freeze-thaw stresses.  
46  
47  
48

49  
50 From an environmental point of view, these results are quite interesting since lamp glass  
51  
52 and the discarded fraction of glass urban collection cannot be reused in the production  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62

1  
2  
3  
4  
5  
6 of new glass items and cannot be recycled without previous chemical treatments in  
7  
8 traditional binders containing Portland cement since they develop alkali-silica reactions.  
9

10  
11 The absence of expansion reactions (either ASR or DEF) further promotes the use of  
12  
13 alkali activated binders that are already considered as green, low carbon dioxide  
14  
15 footprint materials.

Table 1. Oxide content of the investigated materials.

Material	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	Na <sub>2</sub> O	K <sub>2</sub> O	CaO	MgO	PbO	BaO	Fe <sub>2</sub> O <sub>3</sub>	SO <sub>3</sub>	LOI
RUB	66.25	1.88	9.42	5.98	5.60	1.65	6.91	2.21	0.00	0.00	0.00
LMP	68.47	2.26	17.65	1.61	5.13	2.98	0.79	0.95	0.00	0.00	0.00
Fly ash	49.37	29.23	0.05	0.60	6.63	1.05	0.00	0.00	2.71	0.33	3.28

Table 2. Composition and labelling of all investigated samples.

Mortar sample	Natural sand (g)	Glass waste (g)	Sodium silicate solution (g)	NaOH 8M solution (g)	H <sub>2</sub> O (g)	Fly ash (g)	Portland cement (g)
M-REF	1350	0	188	38	35	500	-
M-RUB	1080	270	188	38	35	500	-
M-LMP	1080	270	188	38	35	500	-
M-PRT	1350	0	0	0	225	-	450

Table 3. Physical properties of the investigated mortars.

Sample	M-REF	M-LMP	M-RUB	M-PRT
Workability (%)	59.1 ± 0.6	69.6 ± 0.9	69.0 ± 0.4	41.3 ± 0.8
Density (g/cm <sup>3</sup> )	2.11	2.07	2.03	2.11
Porosity (vol %)	10.76	10.69	10.86	19.50

Fig. 1. Morphology of LMP (a) and RUB (b) cullets.

Fig. 2. Size distribution of natural sand and glass cullets.

Fig. 3. Expansion at 80°C.

Fig. 4. Sharp unreacted contour (arrows) of one LMP cullet in contact with the alkali activated matrix (fracture surface of M-LMP cured at 80°C in NaOH solution).

Fig. 5. Sharp unreacted RUB cullet cured at 80 °C in NaOH solution from M-RUB mortar.

Fig. 6. Expansion vs curing time at 38°C.

Fig.7. Unreacted LMP cullet at 60 days of curing (38 °C) for M-LMP mortar.

Fig. 8. Unreacted RUB cullet at 60 days of curing (38°C) for M-RUB mortar.

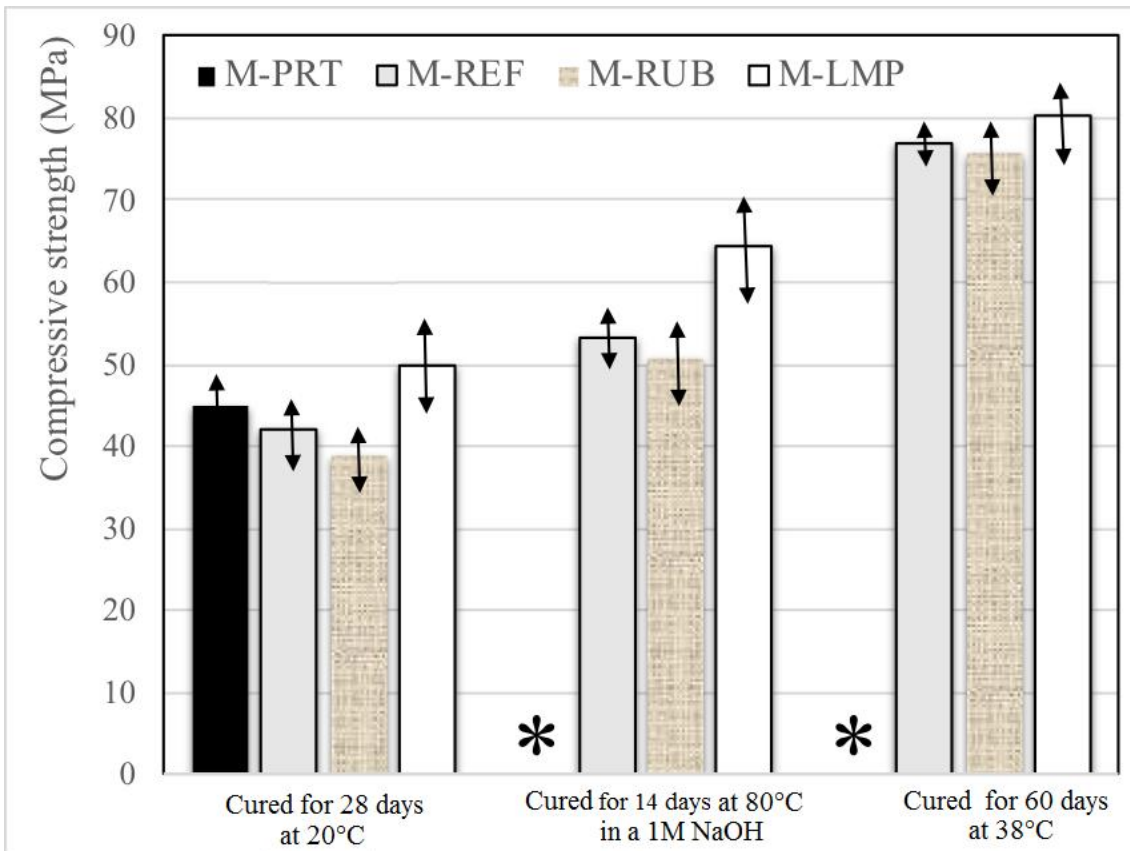

Fig. 9. Mechanical properties of samples in different curing conditions.

(\*) Portland samples not reported since showing expanding behaviour

Fig. 10. Plot of the dynamic elastic modulus vs time of mortars in sulphates solution.

Fig. 11. (a) ettringite samples in M-PRT sample (b) alkali activated matrix of M-RUB sample.

Fig. 12. Elastic modulus vs freeze-thaw cycles.
