## Abstract

**Aims:** Cancer stem cell biology is tightly connected to the regulation of the pro-inflammatory cytokine network. The concept of cancer stem cells “inflammatory addiction” leads to envisage the potential role of anti-inflammatory molecules as new anti-cancer targets. Here we report on the relationship between nuclear receptors activity and the modulation of the pro-inflammatory phenotype in breast cancer stem cells.

**Methods:** Breast cancer stem cells were expanded as mammospheres from normal and tumor human breast tissues and from tumorigenic (MCF7) and non tumorigenic (MCF10) human breast cell lines. Mammospheres were exposed to the supernatant of breast tumor and normal mammary gland tissue fibroblasts.

**Results:** In mammospheres exposed to the breast tumor fibroblasts supernatant, autocrine tumor necrosis factor- $\alpha$  signalling engenders the functional interplay between peroxisome proliferator activated receptor- $\alpha$  and hypoxia inducible factor-1 $\alpha$  (PPAR $\alpha$ /HIF1 $\alpha$ ). The two proteins promote mammospheres formation and enhance each other expression via miRNA130b/miRNA17-5p-dependent mechanism which is antagonized by PPAR $\gamma$ . Further, the PPAR $\alpha$ /HIF1 $\alpha$  interplay regulates the expression of the pro-inflammatory cytokine interleukin-6, the hypoxia survival factor carbonic anhydrase IX and the plasma lipid carrier apolipoprotein E.

**Conclusion:** Our data demonstrate the importance of exploring the role of nuclear receptors (PPAR $\alpha$ /PPAR $\gamma$ ) in the regulation of pro-inflammatory pathways, with the aim to thwart breast cancer stem cells functioning.

## Introduction

Breast cancer is a heterogeneous set of diseases that constitute the leading cause of cancer among women in western countries [1,2]. In the recent past, a minor sub-population of tumor cells endowed with the characteristics of stem cells (named cancer stem cells, CSCs) has been identified [3–5]. It is currently proposed that CSCs provide the cellular substrate for metastatic spreading and relapse and constitute the ultimate targets for innovating cancer therapy [4–6]. CSCs can be studied *in vitro* by expanding multicellular spheroids (mammospheres, MS) from breast cancer

surgical specimens and cell lines [7–9]. The pro-inflammatory cytokine network is of key importance in breast CSCs biology [9,10]. In particular, the pro-inflammatory nuclear factor- $\kappa$ B (NF- $\kappa$ B) pathway, as well the NF- $\kappa$ B-regulated cytokines tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) and interleukin 6 (IL6) trigger MS survival and self-renewal [9–13]. In haematopoietic and prostate CSCs, such a pro-inflammatory phenotype has been associated with a kind of “inflammatory addiction”, which makes CSCs likely targets of anti-inflammatory drugs, that may act as potential enhancers of cancer therapy [14–16].

The stromal cell is the cornerstone of the stem cell niche [17,18]. Stroma-derived inflammatory mediators, such as prostaglandins and IL6 promote MS growth and survival [9,19]. Similarly to its normal counterpart [20], the CSCs niche is characterized by low oxygen tension (hypoxia) which promotes stem cell survival [21]. Hypoxia inducible factor1 $\alpha$  (HIF1 $\alpha$ ) affects a variety of malignant features, such as hypoxic cancer cell survival, via the regulation of a large number of genes, including carbonic anhydrase IX (CAIX) [22,23].

We recently reported that peroxisome proliferator activated receptor- $\alpha$  (PPAR $\alpha$ ) modulates the expression of stem cell genes (e.g. Jagged1) and apolipoprotein E (ApoE) in breast CSCs [24]; ApoE is a lipoprotein over-expressed in MS [7]. PPAR $\alpha$  belongs to the PPAR nuclear receptor family, enlisting also PPAR $\beta$  and PPAR $\gamma$  among its members. PPAR $\alpha$  plays a key role in lipid metabolism and it is activated by fatty acids, leukotriene and synthetic fibrates [25]. PPAR $\gamma$  binds natural molecules, such as prostaglandin J<sub>2</sub>, polyunsaturated fatty acids, and synthetic compounds, such as Pioglitazone (PGZ) [26]. Ligands of PPAR $\gamma$  reduce the viability of cancer cell lines and breast CSCs [24,27–29]. Noteworthy, PPAR $\gamma$  plays a significant inhibitory role on the inflammatory process [30–31], while PPAR $\alpha$  exerts pro-inflammatory activity [32]. Interestingly, the expression of PPAR $\alpha$  increases, while that of PPAR $\gamma$  decreases in neural stem cells exposed to hypoxia [33]. In this study, MS from normal (N-MS) and tumor (T-MS) tissues, as well as from tumorigenic MCF7 (MCF7-MS) and non tumorigenic (MCF10-MS) human breast cell lines, were exposed to the supernatant of normal mammary gland and breast tumor associated fibroblasts. We undertook this approach to elucidate the regulation of PPAR $\alpha$  and PPAR $\gamma$  in the context of breast CSCs inflammatory pathway activation.

## Results

### Enhanced Autocrine TNF $\alpha$ Loop in Breast Cancer Tissue Derived MS Exposed to the Supernatant of Tumor Associated Fibroblasts

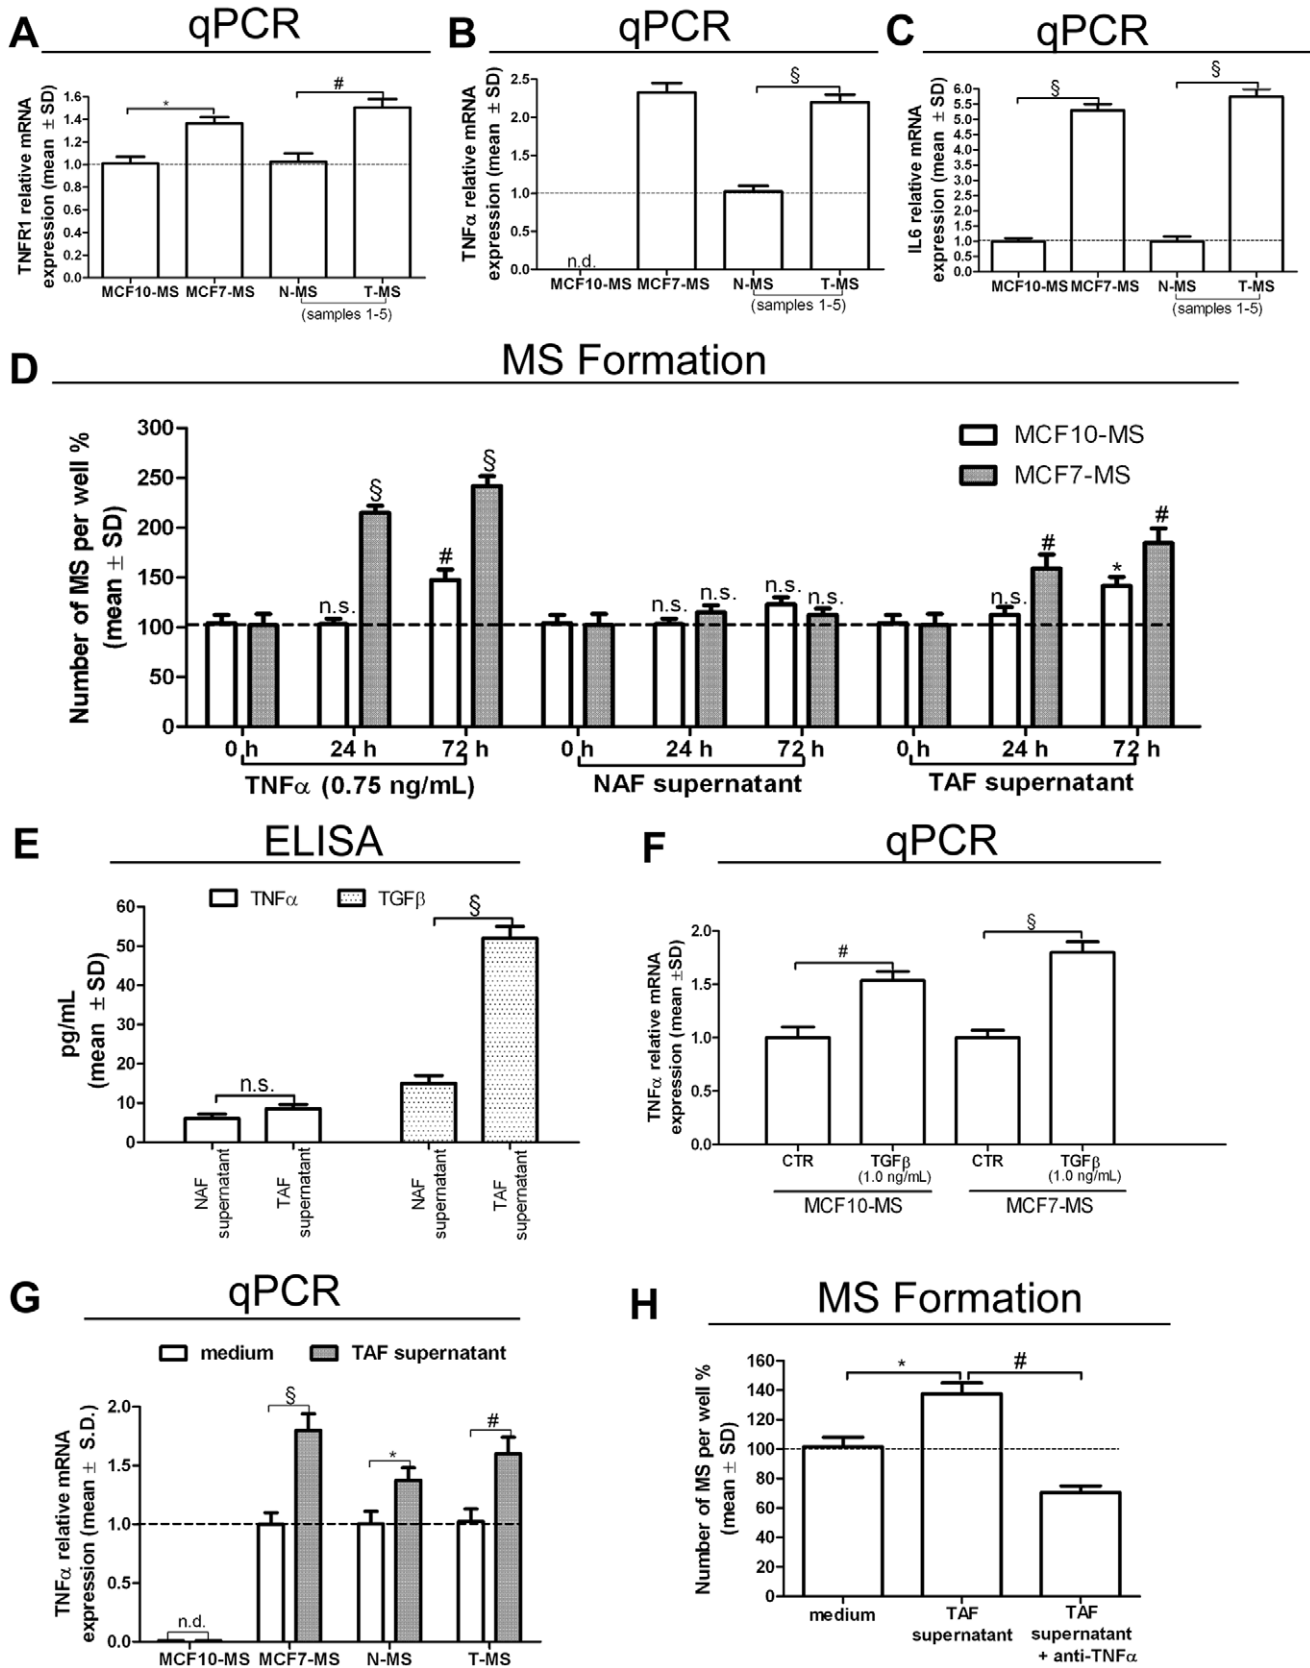

We recently reported the increase of NF- $\kappa$ B activity in breast tumor MS (T-MS), compared to their normal counterparts (N-MS) [24]. The major trigger of NF- $\kappa$ B pathway is TNF $\alpha$ , a potent inducer of MS formation [12,13]. Here we found higher expression of tumor necrosis factor receptor-1 (TNFR1), and of the NF- $\kappa$ B targets TNF $\alpha$  and IL6 in tumorigenic MCF7-MS and T-MS, compared to non tumorigenic MCF10-MS and N-MS, respectively (Figure 1A, B, C). We also observed that exogenous TNF $\alpha$  elicited MS formation in MCF7 to a higher extent than in MCF10 cells, a phenomenon that was mimicked by the administration of the supernatant of tumor associated fibroblasts (TAF), but not of normal mammary gland fibroblasts (NAF, Figure 1D). Both TAF and NAF secreted very low levels of TNF $\alpha$ , whereas TAF secreted higher levels of transforming growth factor- $\beta$ 1 (TGF $\beta$ ) compared to NAF (Figure 1E). TGF $\beta$  is a potent MS growth factor and synergizes with TNF $\alpha$  to induce stem cell features in breast cancer cells [34–35]. With respect to this issue, we observed that TGF $\beta$  was able to induce TNF $\alpha$  expression in MS (Figure 1F). Moreover, the TAF supernatant induced TNF $\alpha$  expression in T-MS and MCF7-MS to a higher extent than in N-MS and MCF10-MS, respectively (Figure 1G). Finally, the increase in T-MS formation following the TAF supernatant administration was halted by TNF $\alpha$  blocking antibody administration (Figure 1H). These data show that autocrine TNF $\alpha$  signalling in breast CSCs is enhanced by TAF secretion of TGF $\beta$ .

### The Tumor Associated Fibroblasts Supernatant Elicits the PPAR $\alpha$ /HIF1 $\alpha$ Interplay Dependent Growth of MS

We recently reported that PPAR $\alpha$  promotes tumor MS formation and the expression of the MS growth factor Jagged1 [24]. In MS exposed to TNF $\alpha$ , we observed increased expression of PPAR $\alpha$  (Figure 2A) and Jagged1 (+153%,  $p < 0.005$ , in MCF10-MS; +167%,  $p < 0.005$ , in MCF7-MS; +63%,  $p < 0.05$ , in N-MS; +76%,  $p < 0.05$  in T-MS, Figure S1A). Moreover, in the same cellular models, the administration of the TAF supernatant up-regulated PPAR $\alpha$  (Figure 2B and +54%,  $p < 0.05$ , in MCF7-MS, Figure S1B) and Jagged1 (+283%,  $p < 0.005$ , in MCF10-MS; +297%,  $p < 0.005$ , in MCF7-MS; +253%,  $p < 0.05$ , in N-MS; +266%,  $p < 0.05$  in T-MS, Figure S1C) to a higher extent than the NAF supernatant. We previously demonstrated that HIF1 $\alpha$  is a TNF $\alpha$  target [12]. Moreover, literature data report that HIF1 $\alpha$  is a potential PPAR $\alpha$  target [33]. Here, we observed that exposure of PPAR $\alpha$  knock-down and MCF10-MS to the TAF supernatant elicited HIF1 $\alpha$  transcriptional activity (Figure 2C) and mRNA expression (+65%,  $p < 0.05$ , in MCF10-MS; +76%,  $p < 0.01$ , in MCF7-MS, Figure S2A). Exposure to hypoxia, meanwhile inducing HIF1 $\alpha$  expression and activity (+63%,  $p < 0.05$ , in MCF10-MS; +85%,  $p < 0.01$ , in MCF7-MS, Figure S2B; +94%,  $p < 0.005$ , in MCF10-MS; +122%,  $p < 0.005$ , in MCF7-MS, Figure S2C), was responsible for an increase in PPAR $\alpha$  expression and MS formation (Figure 2D). The phenomenon was hampered by siRNA-mediated PPAR $\alpha$  knock-down (KD) in normoxic and hypoxic conditions (–63%,  $p < 0.005$  and –56%,  $p < 0.005$  respectively, Figure S2D). Prompted by these data, we investigated the relationship between PPAR $\alpha$  and HIF1 $\alpha$  expression. We observed that siRNA-PPAR $\alpha$  administration reduced, while the PPAR $\alpha$  agonist Wy16463 (WY) triggered the expression of HIF1 $\alpha$  protein expression and transcriptional activity (Figure 2E and Figure 2F). HIF1 $\alpha$  expression was increased also in MCF10-MS exposed to WY (+91%,  $p < 0.01$ , Figure S2E). As a further insight into the PPAR $\alpha$ /HIF1 $\alpha$  interplay, we found that PPAR $\alpha$  expression and peroxisome proliferator response element reporter (PPRELuc) activity were elicited by HIF1 $\alpha$  over-expression and reduced by siRNA-HIF1 in MCF7-MS and T-MS (Figure 2G and Figure 2H). Finally, we verified that the over-expression of PPAR $\alpha$  up-regulated two inducers of MS formation [9,12], namely SLUG (+41%,  $p < 0.05$ , in MCF10-MS, +62%,  $p < 0.01$  in MCF7-MS, Figure S3A) and IL6 (+182%,  $p < 0.01$ , in MCF10-MS; +552%,  $p < 0.005$ , in MCF7-MS, Figure S3B). In MCF7-MS, HIF1 $\alpha$  over-expression triggered, as well as HIF1 $\alpha$  KD hindered the expression of SLUG (+72%,  $p < 0.01$ , –43%,  $p < 0.01$ , respectively, Figure S3C) and IL6 (+295%,  $p < 0.005$ , –36%,  $p < 0.05$ , respectively, Figure S3D). These data suggest that the PPAR $\alpha$ /HIF1 $\alpha$  interplay is active in T-MS to a higher extent than in their normal counterpart and that it drives the expression of MS growth promoting genes.

### PPAR $\gamma$ Expression Antagonizes the PPAR $\alpha$ /HIF1 $\alpha$ Interplay

We pursued our investigation by observing that, opposite PPAR $\alpha$  regulation (see Figure 2G), the transfection of HIF1 vector down-regulated (–59%,  $p < 0.01$ , Figure S4A), as well as siHIF1 up-regulated PPAR $\gamma$  expression (Figure 3A). Interestingly, higher levels of PPAR $\alpha$  mRNA and protein, but reduced mRNA PPAR $\gamma$  levels were found in MCF7-MS and MCF10-MS compared to adherent cells (Figure 3B). Accordingly, similar data were obtained by western blot analysis of PPAR $\alpha$  (+42%,  $p < 0.05$ , in MCF10-MS *vs* MCF10, and +82%,  $p < 0.01$ , in MCF7-MS *vs* MCF7) and PPAR $\gamma$  (–22%,  $p < 0.05$ , in MCF10-MS *vs* MCF10, and –10%,

**Figure 1. Autocrine TNF $\alpha$  loop in MS exposed to the TAF supernatant.** TNFR1 (A), TNF $\alpha$  (B) and IL6 (C) real-time reverse transcriptase quantitative (qPCR) mRNA analysis in MCF7-MS, MCF10-MS, T-MS and N-MS (samples 1–5). (D) MS formation assay in TNF $\alpha$  (0.75 ng/mL), NAF and TAF supernatant (10% final concentration)-exposed MCF10 and MCF7 for 24 to 72 h; (E) TNF $\alpha$  and TGF $\beta$  ELISA test on TAF and NAF supernatants (samples

6–12); (F) TNF $\alpha$  mRNA qPCR analysis in TGF $\beta$  (1.0 ng/mL, 24 h)-exposed MCF10-MS and MCF7-MS (G) TNF $\alpha$  mRNA qPCR analysis in TAF supernatant (10%, 24 h)-exposed MCF10/MCF7-MS, and in N-/T-MS (samples 5–6, n = 2); (H) TAF supernatant-induced T-MS formation assay in presence/absence of TNF $\alpha$  inhibitory antibody (1.5  $\mu$ g/mL, 24 h, sample 13). Data are expressed as mean  $\pm$  Standard Deviation (S.D.), n = 3 unless otherwise specified, \* $p$ <0.05, # $p$ <0.01, § $p$ <0.005, ANOVA test. n.s.: not significant.  
doi:10.1371/journal.pone.0054968.g001

$p$ >0.05, in MCF7-MS vs MCF7, Figure S4B). Owing to PPAR $\gamma$  needs to heterodimerize with retinoid X receptors (RXRs) to exert its transcriptional activity [28], we tested also RXR $\alpha$ , RXR $\beta$  and RXR $\gamma$  expression in MS. As previously demonstrated in MCF7 cells [24], RXR $\alpha$  gene expression was reduced in MS compared to adherent MCF10 cells (–62%,  $p$ <0.01, Figure S4C). Moreover, siHIF1 transfection in MCF7-MS up-regulated RXR $\alpha$  (+83%,  $p$ <0.01) and PPAR $\beta$  (+64%,  $p$ <0.01) expression (Figure S4D). The phenomenon paralleled the up-regulation of PPAR $\gamma$  expression in the same cells (see Figure 3A). We then observed that the PPAR $\gamma$  ligand PGZ reduced HRELuc activity in T-MS (Figure 3C) and HIF1 $\alpha$  expression in MCF7-MS (–37%,  $p$ <0.05) and in T-MS (–26%,  $p$ <0.01, Figure S5A). Further, PGZ reduced MS formation (–23%,  $p$ <0.05, in MCF7-MS and –27%,  $p$ <0.01, in T-MS, Figure S5B) and the expression of breast CSCs regulatory pathway [9] in hypoxic MCF7-MS (–25%,  $p$ <0.05 for IL6, –22%,  $p$ <0.05 for Notch3, –21%,  $p$ <0.05 for Jagged1, Figure S5C) and T-MS (–55%,  $p$ <0.05 for IL6, –57%,  $p$ <0.05 for Notch3, –51%,  $p$ <0.05 for Jagged1, Figure S5C). Finally, luciferase reporter assay showed that PGZ inhibited the activity of NF- $\kappa$ B and of the NF- $\kappa$ B targets IL6 and SLUG promoters (Figure 3D). In line with these data, PGZ inhibited the expression of IL6 (–19%,  $p$ <0.05), Interleukin 8 (IL8, –31%,  $p$ <0.05), SLUG (–18%,  $p$ <0.05) and TNF $\alpha$  (–54%,  $p$ <0.01) in the breast cancer estrogen receptor- $\alpha$  (ER $\alpha$ ) negative cell line MDA-MB-231 (Figure S6). These data point out the reciprocal antagonistic role of PPAR $\gamma$  and PPAR $\alpha$  in breast CSCs, in which the former facilitates and the latter opposes the expression of breast CSCs regulatory pathway.

### Opposing Roles of miRNA130b and miRNA17-5p on the PPAR $\alpha$ /HIF1 $\alpha$ Interplay

To mechanistically elucidate the PPAR $\alpha$ /HIF1 $\alpha$  interplay, we examined microRNA130b (miR130b) expression. This microRNA was chosen basing on two considerations: i. its capability to increase HIF1 $\alpha$  expression via the down-regulation of the HIF1 $\alpha$  mRNA translation inhibitory protein DDX6 [36]; ii, the presence of its binding site at PPAR $\gamma$  mRNA 3'UTR [37]. We observed that the miR130b up-regulation in TAF supernatant-exposed MCF7-MS (Figure 4A) was paralleled by the reduction of DDX6 expression in MS (Figure 4B). Accordingly, the administration of miR130b antagonist (a-miR130b) in MCF7-MS reduced the activity of HRELuc (Figure 4C) and induced DDX6 expression (Figure 4D). We then observed the up-regulation of miR130b expression in MCF7- and MCF10-MS compared to adherent cells (Figure 4E). In keeping with the results above reported, miR130b expression was down-regulated by siHIF1 and siPPAR $\alpha$ , and it was induced by PPAR $\alpha$  over-expression in MCF7-MS (Figure 4F). Finally, the transfection of pre-miR130b increased PPAR $\alpha$  expression in MCF7-MS (Figure 4G).

Further insight into the PPAR $\alpha$ /HIF1 $\alpha$  interplay was obtained via the assessment of microRNA17-5p (miR17-5p), whose binding consensus is present at PPAR $\alpha$  mRNA 3'UTR. In respect to this issue, we were allowed to observe that miR17-5p expression was decreased by TNF $\alpha$  administration in MCF7-MS (Figure 5A). Further, miR17-5p transfection down-regulated PPAR $\alpha$ , as well as miR17-5p antagonist (a-miR17-5p) induced PPAR $\alpha$  expression (Figure 5B). In the same experimental setting, miR17-5p increased

PPAR $\gamma$  expression and a-miR17-5p reduced PPAR $\gamma$  expression (Figure 5C). Finally, the administration of PGZ increased miR17-5p expression (Figure 5D), while it dampened PPAR $\alpha$  expression in MCF7-MS (Figure 5D). These data point out that the antagonist interplay between PPAR $\alpha$  and PPAR $\gamma$  is mediated by miR130b and miR17-5p.

### CAIX Over-expression in Tumor MS is Under the Control of the PPAR $\alpha$ /HIF1 $\alpha$ Interplay

CAIX is a tumor antigen and it is an acknowledged HIF1 $\alpha$  target [38], also in MCF7-MS, where it is up-regulated by HIF1 $\alpha$  over-expression (+93%,  $p$ <0.01) and down-regulated by HIF1 $\alpha$  KD (–46%,  $p$ <0.01, Figure S7A). We observed that CAIX was expressed to a higher extent in T-MS than in N-MS (Figure 6A), as well as in MCF7-MS than in MCF10-MS (+61%,  $p$ <0.05, MCF10-MS vs MCF10; +45%,  $p$ <0.05, MCF7-MS vs MCF7, Figure S7B). Accordingly, CAIX promoter activity (CAIXLuc) was higher in MCF7-MS compared to MCF10-MS (Figure 6B). Moreover, the exposure to the TAF supernatant elicited CAIX expression (Figure 6C). We then demonstrated that PPAR $\alpha$  over-expression induced the expression of CAIX in MCF7-MS (+63%,  $p$ <0.01, Figure S7C), but not in MCF10-MS (Figure 6D). Accordingly, siPPAR $\alpha$  transfection hampered (–24%,  $p$ <0.05), as well as the PPAR $\alpha$  agonist WY triggered (+25%,  $p$ <0.05) CAIXLuc activity in MCF7-MS (Figure S7D). Interestingly, the siRNA mediated KD of CAIX (siCAIX) reduced PPRELuc activity in T-MS and MCF7-MS, but neither in N-MS nor in MCF10-MS (Figure 6E). In turn, PGZ reduced CAIX expression (Figure 6F) and CAIXLuc activity (Figure 6G) in MCF7-MS and T-MS. Intriguingly, PGZ reduced CAIX expression (–31%,  $p$ <0.05) also in TAF (Figure S8). These data point out that the PPAR $\alpha$ /HIF1 $\alpha$  interplay controls CAIX expression in CSCs.

### ApoE Over-expression in T-MS is Under the Control of the PPAR $\alpha$ /HIF1 $\alpha$ Interplay

PPAR $\alpha$  is involved in a wide variety of cellular functions, including lipid homeostasis [39]. Moreover, PPRE consensus sequence occurs at the promoters of lipid transporters, such as apolipoproteins [39]. Interestingly, ApoE is over-expressed in MS [7,24]. Here, we were able to quantify the over-expression of ApoE in T-MS compared to N-MS, as well as in MCF7-MS compared to MCF10-MS (Figure 7A). We also found ApoE over-expression in MCF7-MS and MCF10-MS in response to exogenous TNF $\alpha$  and to the TAF supernatant administration (Figure 7B). Then, we demonstrated that PPAR $\alpha$  over-expression induced the mRNA expression (Figure 7C) and protein (+81%,  $p$ <0.01, Figure S9A) of ApoE in MCF7-MS. As expected, the phenomenon was mimicked by the administration of WY (+127%,  $p$ <0.005, in MCF10-MS and +135%,  $p$ <0.005, in MCF7-MS, Figure S9B). Furthermore, HIF1 vector elicited (+44%,  $p$ <0.05, Figure S9C), as well as siHIF1 reduced the expression of ApoE in MCF7-MS (Figure 7D). These data show that ApoE over-expression in breast cancer stem cells is under the control of the PPAR $\alpha$ /HIF1 $\alpha$  interplay.

We thereafter investigated the effects of the inhibition of ApoE expression in MS. siRNA-mediated (siApoE) KD of ApoE mRNA (–77%,  $p$ <0.005 in MCF10-MS, –82%,  $p$ <0.005 in MCF7-MS,

**Figure 2. The TAF supernatant induces the PPAR $\alpha$ /HIF1 $\alpha$  interplay and promotes T-MS growth.** PPAR $\alpha$  mRNA qPCR analysis in MCF10/MCF7-MS and N-T-MS (samples 14 and 15) upon exposure to: (A) TNF $\alpha$  (0.75 ng/mL, 24 h), (B) NAF or TAF supernatant (10%, 24 h), (C) HRELuc activity in NAF or TAF supernatant (10%, 24 h)-exposed MCF10/MCF7-MS. (D) MS formation assay in scramble (SCR)/siPPAR $\alpha$  (72 h)-transfected MCF10 and MCF7 cells in normoxia (20% pO $_2$ ) or hypoxia (1% pO $_2$ ). HIF1 $\alpha$  and PPAR $\alpha$  protein expression (E) and HRELuc activity (F) in SCR/siPPAR $\alpha$  (72 h)-transfected or PPAR $\alpha$  agonist WY (10  $\mu$ M, 24 h)-exposed hypoxic MCF7-MS. PPAR $\alpha$  mRNA qPCR analysis (G) and PPRELuc activity (H) in HIF1 vector (48 h) and SCR/siHIF1 (72 h)-transfected MCF7-MS and T-MS (samples 15–17). Data are expressed as mean  $\pm$  S.D., n=3 unless otherwise specified, \* $p$ <0.05, # $p$ <0.01, § $p$ <0.005, ANOVA test. n.s.: not significant. doi:10.1371/journal.pone.0054968.g002

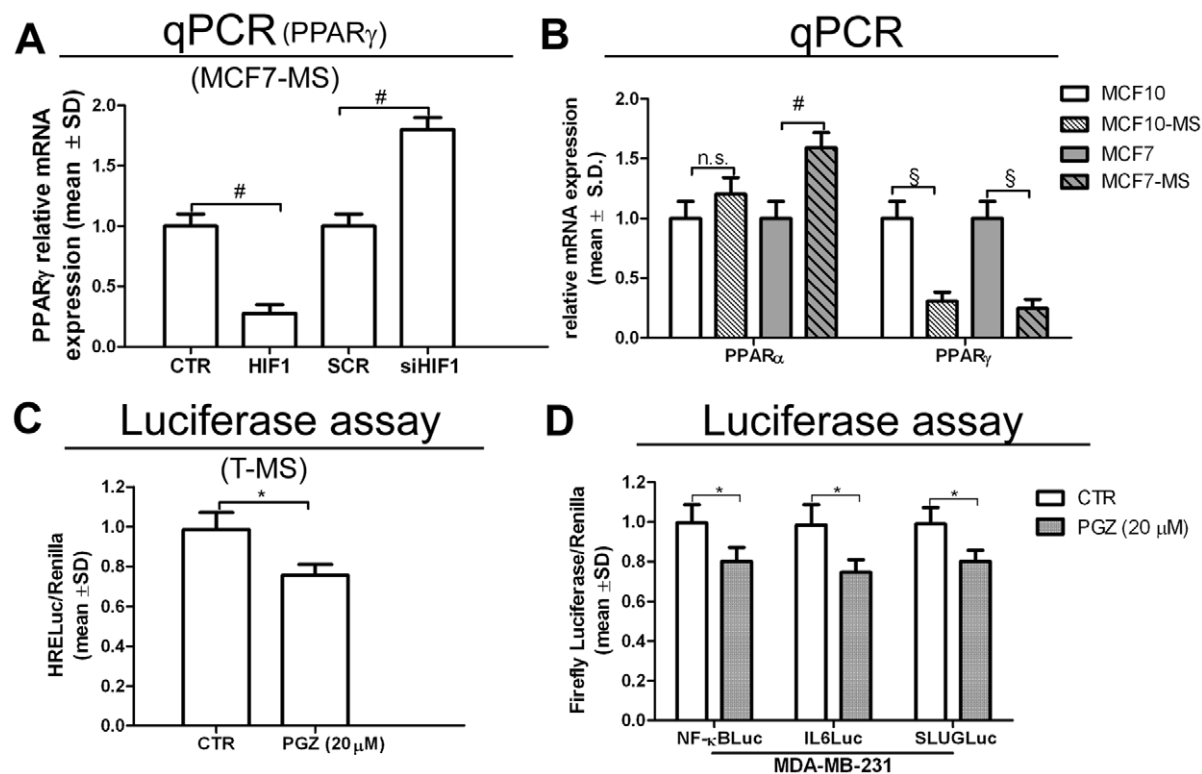

Figure S9D) and protein ( $-69\%$ ,  $p$ <0.01, in MCF7-MS, Figure S9E) reduced PPAR $\alpha$  expression, PPRELuc activity and MCF7-MS formation capability (Figure 8A, B, C). ApoE KD also elicited the expression of the differentiation markers keratin-18 (KRT18) and ER $\alpha$ , and reduced the expression (Figure 8D) and the promoter activity (Figure 8E) of CAIX, IL6 and SLUG genes. Consistent with the expectations was the finding that PGZ hindered ApoE mRNA expression in MCF7-MS and T-MS (Figure 8F) and ApoE protein expression in MCF7-MS (Figure 8G), but not in MCF10-MS (Figure S10). These data point at the role of the PPAR $\alpha$ /HIF1 $\alpha$  interplay in the regulation of ApoE in CSCs.

## Discussion

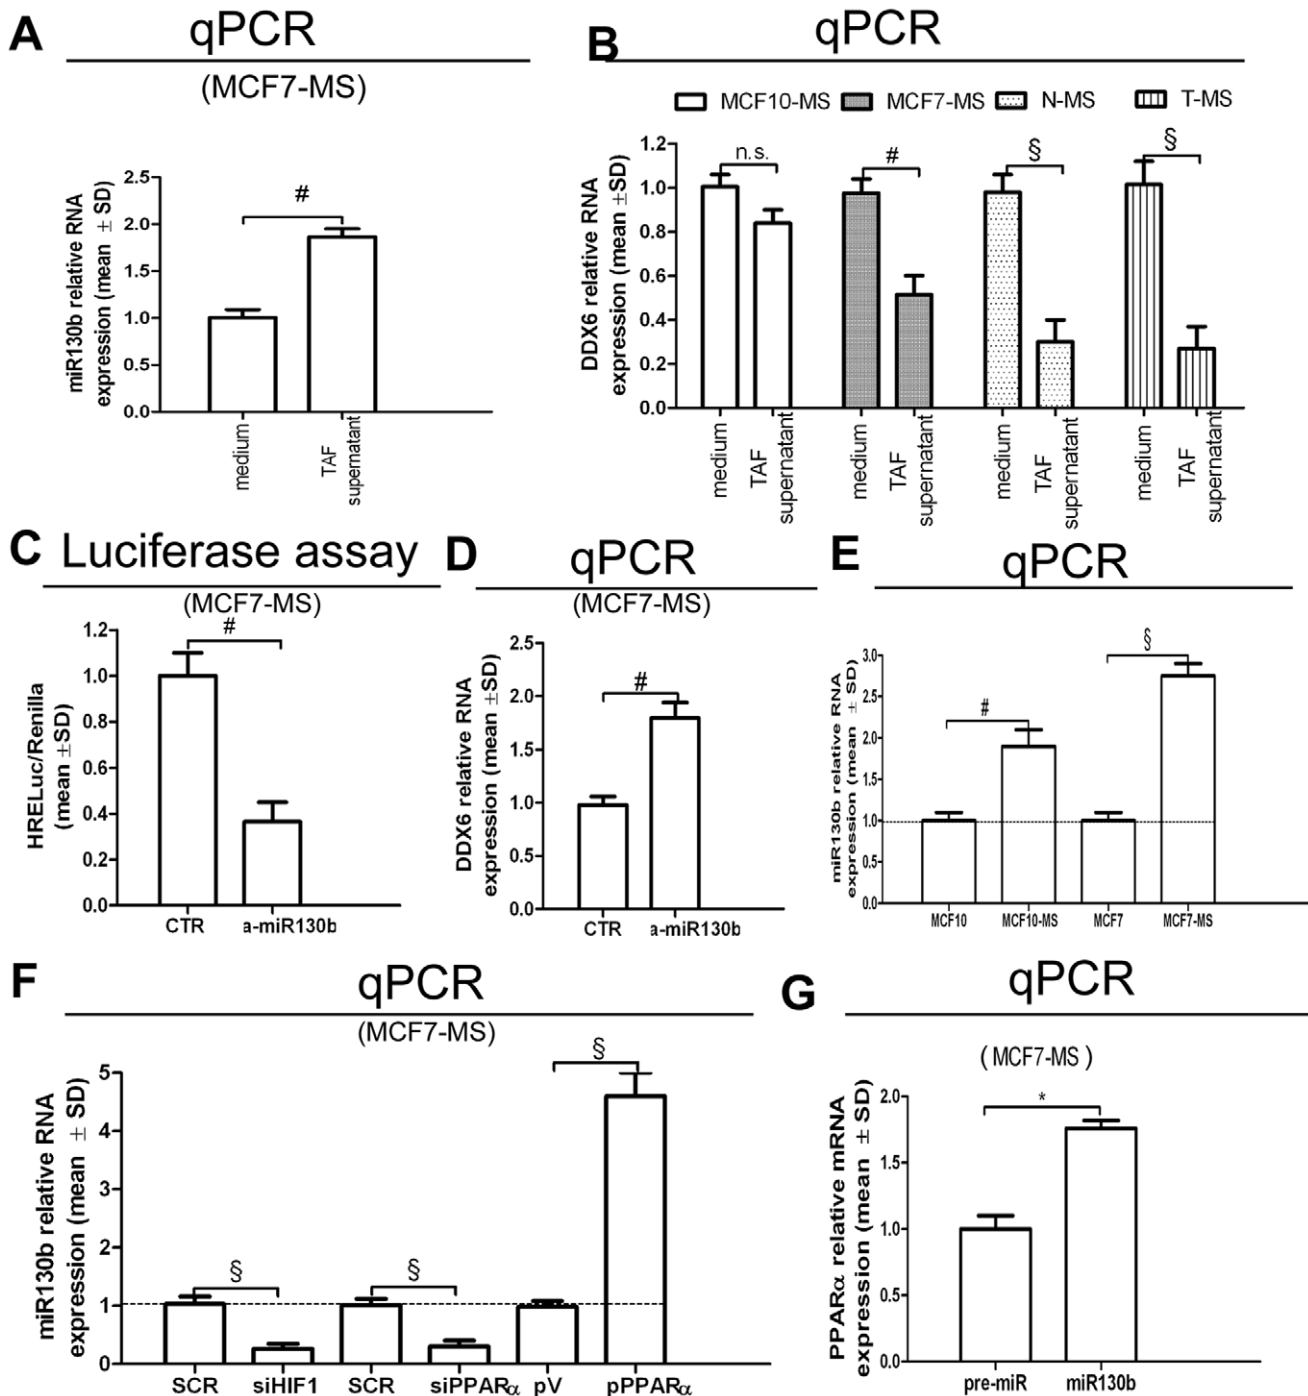

Our investigation started with the observation that human models for breast CSCs (T-MS and MCF7-MS) display increased TNFR1 compared to their normal/non tumorigenic counterparts (N-MS and MCF10-MS). Breast CSCs also exhibit an increased growth response to the TAF supernatant. Though TAF secrete low amounts of TNF $\alpha$ , we demonstrate that TAF elicit TNF $\alpha$

expression in CSCs by secreting TGF $\beta$ , thus setting up an autocrine TNF $\alpha$  loop that enhances MS growth. TNFR1 signalling is a major inducer of inflammatory response via NF- $\kappa$ B activation [40–43]. The expression of the two NF- $\kappa$ B targets TNF $\alpha$  and IL6 is higher in CSCs, and both these cytokines have been previously shown to elicit MS formation [12–13,44,45]. Collectively, the findings here reported, together with previous data concerning the increase of NF- $\kappa$ B activity in T-MS [24], contribute to the tenet that CSCs are endowed with pro-inflammatory phenotype [14,16,18].

We then pinpoint that the core of such TAF-promoted pathway involves the PPAR $\alpha$ /HIF1 $\alpha$  interplay. In particular, the two proteins induce each other expression and trigger T-MS growth to a higher extent than their normal counterpart. In this regard, we show the involvement of miR130b. Over-expression of this microRNA has been previously reported in liver cancer and pluripotent stem cells [46,47]. Moreover, miR130b is induced by hypoxia and increases HIF1 $\alpha$  protein expression by facilitating HIF1 $\alpha$  mRNA translation, via the down-regulation of DDX6 expression [36]. Here, we report that miR130b up-regulates

**Figure 3. PPAR $\gamma$  antagonizes the PPAR $\alpha$ /HIF1 $\alpha$  interplay and inhibits pro-inflammatory CSCs pathways.** (A) PPAR $\gamma$  mRNA qPCR analysis in HIF1 vector (48 h) or SCR/siHIF1 (72 h)-transfected MCF7-MS. doi:10.1371/journal.pone.0054968.g004

HIF1 $\alpha$  activity (as well as down-regulates DDX6 expression), and that the up-regulation of the PPAR $\alpha$ /HIF1 $\alpha$  interplay is paralleled by the down-regulation of PPAR $\gamma$ , a miR130b target [37]. In regard to this issue, we provide evidence that the PPAR $\gamma$  agonist PGZ, which up-regulates PPAR $\gamma$  expression and activity [24],

hinders the PPAR $\alpha$ /HIF1 $\alpha$  interplay in breast CSCs. We propose that this phenomenon is mediated by miR17-5p which targets both PPAR $\alpha$  and HIF1 $\alpha$  mRNA 3'UTRs [48]. With respect to this issue, we show that miR17-5p expression is up-regulated by PGZ and that miR17-5p knock-down increases PPAR $\alpha$  expres-

**Figure 5. Role of miR17-5p on the PPAR $\alpha$ /PPAR $\gamma$  interplay in breast CSCs.** (A) miR17-5p qPCR analysis in TNF $\alpha$  (0.75 ng/mL, 24 h)-exposed MCF7-MS. PPAR $\alpha$  mRNA (B) and PPAR $\gamma$  mRNA (C) qPCR analysis in pre-miR17-5p or antago-miR17-5p (a-miR17-5p)-transfected MCF7-MS (48 h). miR17-5p (D) and PPAR $\alpha$  mRNA (E) qPCR analysis in PGZ (20  $\mu$ M, 24 h)-exposed MCF7-MS. Data are expressed as mean  $\pm$  S.D., n = 3, \* $p$  < 0.05, # $p$  < 0.01, § $p$  < 0.005, ANOVA test. n.s.: not significant. doi:10.1371/journal.pone.0054968.g005

sion, concomitantly with the reduction of PPAR $\gamma$  expression. Thus, miR17-5p may mediate the PPAR $\alpha$ /HIF1 $\alpha$  interplay switch-off throughout the induction of PPAR $\gamma$  over-expression. Interestingly, miR17-5p has been previously found to be repressed by hypoxia [49]. Nevertheless, miR17-5p has been reported as a pro or anti oncogenic miR depending upon the genetic and environmental context [50].

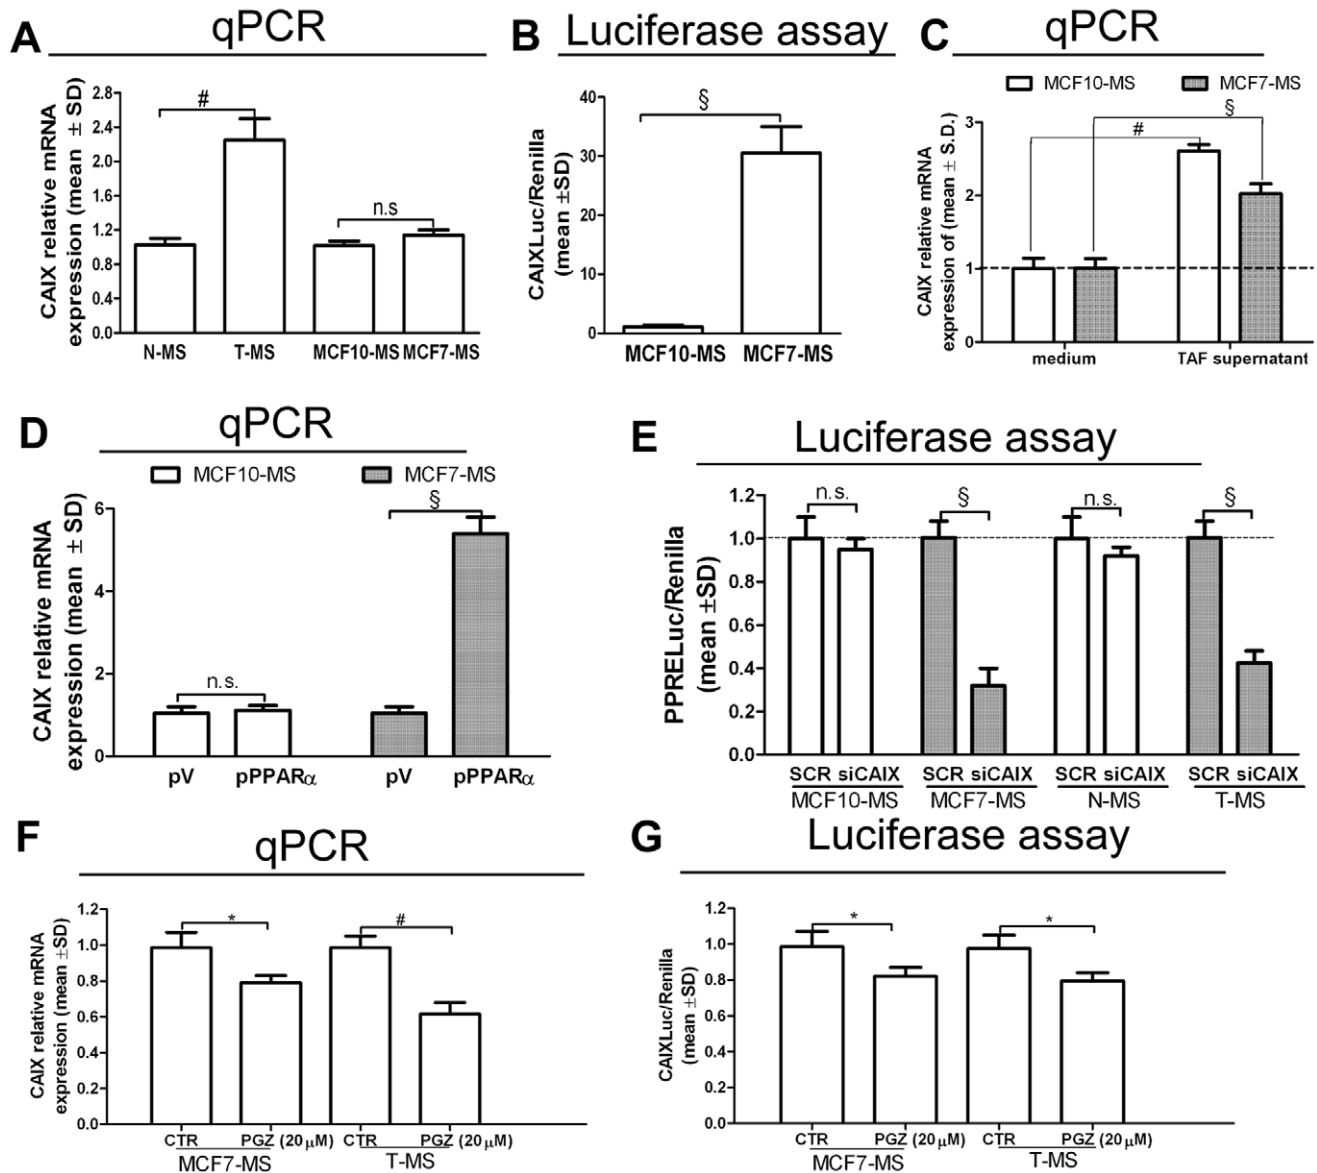

We identified two acknowledged regulators of breast CSCs, namely IL6 and SLUG as targets of the PPAR $\alpha$ /HIF1 $\alpha$  interplay. The former has been characterized as crucial mediator of breast CSCs growth capacity *in vitro* [10]. The latter was recently demonstrated to play a pivotal role in normal and tumor mammary gland self renewal in human and mice [5,12]. We however focussed our attention on two additional targets of the PPAR $\alpha$ /HIF1 $\alpha$  interplay. The former target is the hypoxia inducible gene CAIX, which we found over-expressed in T-MS, in compliance with its original definition as tumor antigen [51]. We previously reported that CAIX expression is crucial for MS hypoxia survival [9,22]. Other investigations showed that CAIX sustains breast cancer survival and invasive behaviour [52]. CAIX is an HIF1 $\alpha$  target and contributes to cancer aggressiveness in various biological contexts, such as the basal-like breast tumor subtype [12,53]. The data here presented lead to hypothesize that CAIX over-expression in CSCs may be the consequence of cues that pertain to the cancer stem cell niche. These data encourage to pursue the ongoing research on CAIX inhibitory molecules as anti cancer agents [54].

The latter target controlled by the PPAR $\alpha$ /HIF1 $\alpha$  interplay is ApoE, a major component of circulating lipoproteins [55].

Here we found the over-expression of ApoE in T-MS, recalling a similar finding in prostate CSCs [14]. We then demonstrate that ApoE knock-down reduces MS formation and the expression of CAIX, IL6 and SLUG [5,12]. These data agree on the role of ApoE in breast cancer aggressiveness. In fact, ApoE plays a crucial role in human pathology, as the  $\epsilon$ 4 allele represents a frailty variant that predisposes to various age-related diseases [56]. ApoE knock-out mice disclose increased mammary tumor incidence, likely in relationship with their hyperlipidemic state [57]. Intriguingly, ApoE physically interacts with HCCR-1, an onco-protein that promotes breast cancer [58]. However, the relationship between breast cancer and ApoE in humans is still under debate, and ApoE may impact disease susceptibility or response to therapy [59,60]. Interestingly, whereas ApoE is likely to impact cardiovascular diseases due to an alteration of the circulating lipidic profile, its role in cancer seems to be independent of this association [61].

In conclusion, we show that the PPAR $\alpha$ /HIF1 $\alpha$  interplay, triggered in breast CSCs by the tumor associated fibroblast secreted TGF $\beta$ , engenders the expression of two acknowledged breast CSCs regulatory genes (IL6 and SLUG), as well as up-regulates two less characterized regulators of breast CSCs, namely CAIX and ApoE (Figure 9). This molecular machinery is counter-acted by PPAR $\gamma$  expression. Our data lead to envisage the possibility to harness nuclear receptor regulation of pro-inflammatory pathways to negatively interfere with CSCs survival.

**Figure 6. CAIX is under the control of the PPAR $\alpha$ /HIF1 $\alpha$  interplay in breast CSCs.** (A) CAIX mRNA qPCR analysis in MCF10/MCF7-MS and in N/T-MS (samples 1–5,  $n=5$ ). (B) CAIXLuc activity in MCF10-MS and MCF7-MS. (C) CAIX mRNA qPCR analysis in TAF supernatant (10%, 24 h)-exposed MCF7-MS and MCF10-MS. (D) CAIX mRNA qPCR analysis in pV/pPPAR $\alpha$  (24 h)-transfected MCF10-MS and MCF7-MS. (E) PPRELuc activity in SCR/siCAIX (72 h)-transfected MCF10/MCF7-MS and N/T-MS (samples 16–18). CAIX mRNA qPCR analysis (F), CAIXLuc activity assay (G) in PGZ (20  $\mu$ M, 24 h)-exposed MCF7-MS and T-MS (samples 19–20): Data are expressed as mean  $\pm$  S.D.,  $n=3$  unless otherwise specified, \* $p<0.05$ , # $p<0.01$ , § $p<0.005$ , ANOVA test. n.s.: not significant. doi:10.1371/journal.pone.0054968.g006

## Materials and Methods

### Chemicals

Recombinant human IL6, TGF $\beta$ , TNF $\alpha$ , and anti-human TNF $\alpha$  inhibitory antibody were purchased from Sigma (St Louis, MO, USA) and dissolved in phosphate buffered saline (1 mg/mL). The PPAR $\gamma$  agonist PGZ (Alexis, Lausen, Switzerland) and the PPAR $\alpha$  agonist WY (Sigma) were dissolved in dimethylsulfoxide (0.1 M).

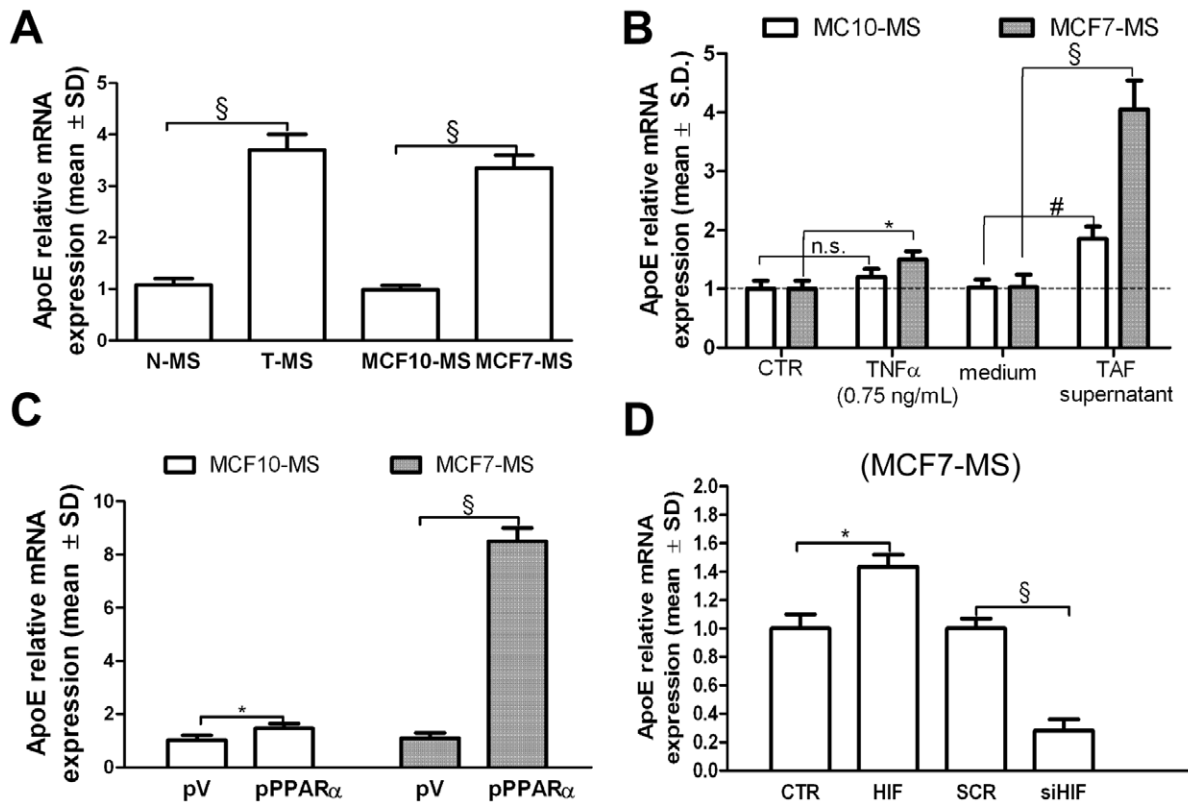

### Plasmids, microRNA and siRNA Transient Transfection

PPAR $\alpha$  (pPPAR $\alpha$ ) and empty (pV) plasmids were obtained from Institute Pasteur (Lille, France). HIF1 plasmid was obtained from

Eric Huang (Department of Neurosurgery, University of Utah, Salt Lake City, Utah, USA). PPAR $\alpha$  and ApoE specific double-strand RNA oligonucleotides (siRNA) and appropriate scramble siRNA (SCR) were purchased from Origene (Rockville, MD, USA). CAIX and HIF1 siRNA and appropriate control SCR siRNAs were purchased from Invitrogen (Rockville, MD, USA). Pre-miRNA17-5p, miRNA130b, antago-miRNA17-5p and miRNA130b were purchased from Life Technologies (Rockville, MD, USA).

### Cell Cultures and Generation of MCF7 and MCF10 MS

MCF7 were grown in RPMI 1640 medium supplemented with 10% FBS, penicillin-streptomycin and glutamine. MCF10 [62]

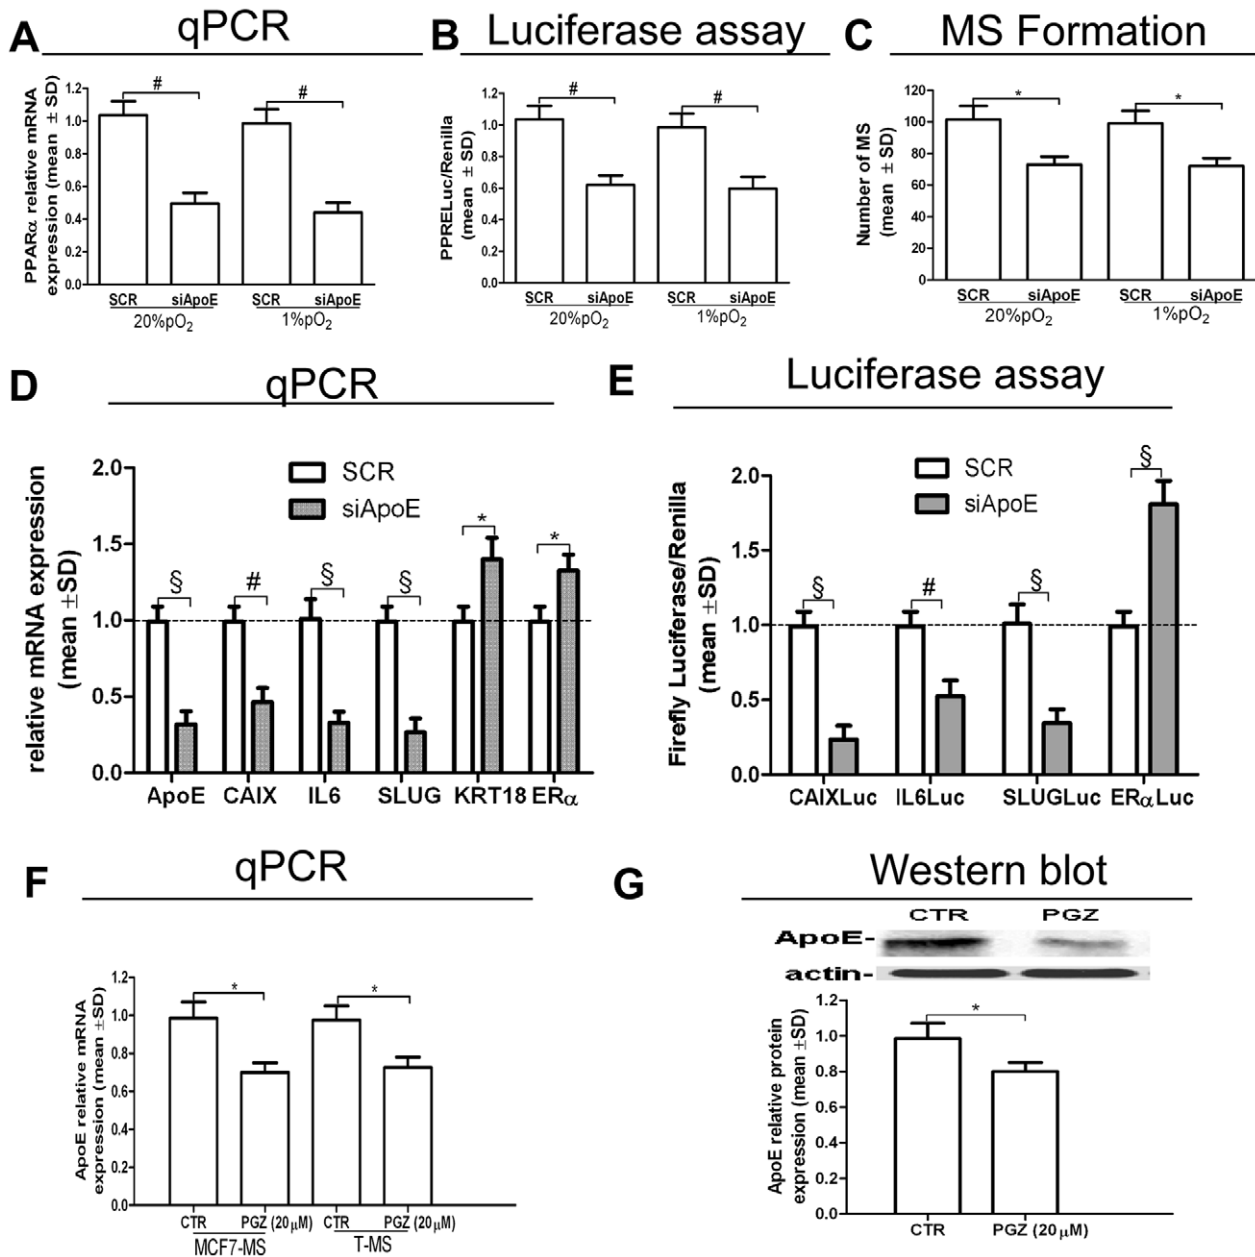

**Figure 7. ApoE is under the control the PPAR $\alpha$ /HIF1 $\alpha$  interplay in breast CSCs.** (A) ApoE mRNA qPCR analysis in N-/T-MS (samples 1–5) and in MCF10/MCF7-MS. (B) ApoE mRNA qPCR analysis in TAF supernatants (10%, 24 h), TNF $\alpha$  (0.75 ng/mL, 24 h)-exposed MCF7-MS. ApoE mRNA qPCR analysis in (C) pV/pPPAR $\alpha$  (48 h)-transfected MCF7-MS and MCF10-MS, and in (D) HIF1 vector (48 h) or SCR/siHIF1 (72 h)-transfected MCF7-MS. Data are expressed as mean  $\pm$  S.D.,  $n=3$ , \* $p<0.05$ , # $p<0.01$ ,  $^{\S}p<0.005$ , ANOVA test. n.s.: not significant. doi:10.1371/journal.pone.0054968.g007

were grown in DMEM medium with 20% FBS, supplemented with 10  $\mu$ g/ml insulin, 10  $\mu$ M hydrocortisone and 10  $\mu$ g/ml EGF. Hypoxia (1% pO $_2$ ) was generated in an Vivo $^2$ 300 hypoxic workstation (Ruskin Technologies, Ireland). MCF7-MS and MCF10-MS were generated by plating 2500 cells into 3-cm $^2$  low-attachment wells (Corning, NY, USA) in mammary epithelial growth medium (MEGM), supplemented with B27, 10 ng/ml epidermal growth factor (EGF), 10 ng/ml basic fibroblast growth factor (bFGF), 10  $\mu$ g/ml insulin, 10 $^{-6}$  M hydrocortisone (Voden Medical, Rome, Italy). Primary MS formation usually occurs after 48 to 72 h. To examine the effects of chemicals on MS formation and MS gene expression, MCF7-MS and MCF10-MS were exposed to each molecule and assessed after 24 h to 72 h. MS with an apparent diameters  $\geq 50$   $\mu$ m were scored and photographed using an inverted microscope (Olympus CKX41, digital cameras Olympus C-5060, Japan). To examine the impact of each specific expression vector, siRNA or pre/antago-miR on MS formation and MS gene expression, adherent MCF7 or MCF10 (10 $^5$  cells in a 3-cm $^2$  well) were transfected with 1  $\mu$ g/well of each siRNA or pre/antago-miR using Lipofectamine 2000 (Invitrogen, USA). After 6 h of incubation, cells were re-suspended, seeded in 24-well ultra-low attachment plates at a density of 2500 cells per well and assessed after 48 h or 72 h. The Effect of each specific treatment was determined by at least  $n=3$  independent experiments. MDA-MB231 cells were grown in RPMI 1640 medium supplemented with 10% FBS, penicillin-streptomycin and glutamine.

#### Generation of MS from Normal and Breast Carcinoma Human Tissues

Twenty-two fresh surgical specimens, obtained from patients with ductal breast carcinoma who underwent quadrantectomy or mastectomy, were collected for the study (Table S1). Normal and tumor samples were processed as previously described [9,12]. Briefly, tissues were placed in sterile Epicut (Voden Medical), minced with sterile scalpels, and incubated for 6–12 h in the presence of 1000 U Collagenase/Hyaluronidase enzyme mix (Voden Medical). Samples were centrifuged at 80  $\times$ g, and the pellet was digested by Dispase and DNase (Voden Medical), and then pelleted at 450  $\times$ g. Pellets were re-suspended, filtered through a 40- $\mu$ m nylon mesh (Voden Medical), and plated into 3-cm $^2$ -well low attachment plates (Corning, NY, USA), filled with 3 ml MEGM, supplemented with B27, 10 ng/ml EGF, 10 ng/ml bFGF, 10  $\mu$ g/ml insulin, 10 $^{-6}$  M hydrocortisone (Voden Medical). Primary MS started forming after 4–6 days and were processed at day 14. Self-renewal of MS was tested by assessing the capacity of primary MS to generate secondary MS after trypsin disaggregation. Transfection in primary T-MS was performed by mixing 1  $\mu$ g of each expression vector or siRNA with in vitro JET-PEI reagent (Poly-plus transfection, USA). The procedure was approved by the local ethical committee of Center for Applied Biomedical Research, St. Orsola-Malpighi University Hospital (Bologna, Italy) (Prot n.75/2011) and by the patients' written informed consent.

**Figure 8. Inhibition of ApoE expression in T-MS.** (A) PPAR $\alpha$  mRNA qPCR analysis, (B) PPRELuc activity and (C) MS formation assay in siApoE (48 h)-transfected MCF7 cells, in normoxic and hypoxic condition; (D) ApoE CAIX, IL6, SLUG, KRT18 and ER $\alpha$  mRNA qPCR analysis in siApoE (48 h)-transfected MCF7-MS. (E) CAIXLuc, IL6Luc, SLUGLuc and ER $\alpha$ Luc activity in siApoE (48 h)-transfected MCF7-MS; ApoE mRNA qPCR analysis (F) and ApoE protein expression (G) in PGZ (20  $\mu$ M, 24 h)-exposed MCF7-MS and T-MS (samples 19–20). Data are expressed as mean  $\pm$  S.D., n = 3, \* $p$  < 0.05, # $p$  < 0.01, § $p$  < 0.005, ANOVA test. n.s.: not significant. doi:10.1371/journal.pone.0054968.g008

### Isolation of Fibroblasts from Normal and Tumour Breast Tissues and Collection of the Fibroblasts Supernatant

Fibroblasts were collected by centrifuging the Collagenase/Hyaluronidase digested tissue lysates used for MS generation at 500 $\times$ g for 5 min (see above). The fibroblasts containing pellet was re-suspended and cultured in DMEM medium with 20% fetal bovine serum (FBS, Euroclone, Milan, Italy), penicillin-streptomycin and glutamine (Sigma), in 6-well plates. When the fibroblasts reached confluence, medium was discarded and replaced with fresh medium, containing DMEM+FBS 0.5% (1.5 mL/well), for 24 h. Supernatants were then collected,

centrifuged for 5 min at 10<sup>5</sup> $\times$ g to remove debris and conserved at  $-80^{\circ}$ C. For the experimental setting supernatants were diluted in MS medium (MEGM) at the final concentration of 10%, and already formed MS were exposed for 24–72 h.

### RNA Extraction, Real-time Reverse Transcription Quantitative PCR (qPCR) and Reverse Transcription PCR (RT-PCR)

Total RNA was extracted from cultured cells, MS and fibroblasts using TRIzol (Life Technologies, Rockville, MD, USA) reagent following the customer's instructions. Real-time

**Figure 9. Schematic representation of the data.** TAF secreted TGF $\beta$  induces TNF $\alpha$  expression in breast CSCs. TNF $\alpha$  binds TNFR1 on breast CSCs and activates the PPAR $\alpha$ /HIF1 $\alpha$  interplay which up-regulates miR130b expression. The interplay is counterbalanced by PPAR $\gamma$  via miR17-5p up-regulation. In turn, the PPAR $\alpha$ /HIF1 $\alpha$  interplay regulates CAIX, ApoE, IL6 and SLUG expression. doi:10.1371/journal.pone.0054968.g009

Reverse Transcription quantitative PCR (qPCR) analysis was performed by TaqMan approach in a Gene Amp 7000 Sequence Detection System (Life Technologies, Rockville, MD, USA), as previously described [24]. Each sample was analyzed in replicates ( $n = 3$ ). Sets of primers and fluorogenic probes specific for the target genes (Table S2) were purchased from Applied Biosystems; qPCR conditions are: pre-denaturation step at 95°C for 2 min; 28 cycles of denaturation at 95°C for 1 min, annealing at the appropriate temperature for 1 min, extension at 72°C for 1 min; final extension at 72°C for 7 min. Human beta-glucuronidase was used as an endogenous control for mRNA level. 6 URNP was used as an endogenous control for miRNA level. The relative amount of each target mRNA or miRNA was calculated as:  $N \text{ target } 2^{-(\text{DCt sample} - \text{DCt calibrator})}$ , where DCt values of the sample and calibrator were determined by subtracting the Ct value of the endogenous control gene from the Ct value of each target gene. RT-PCR analysis was performed using the Master RT plus PCR system kit according to the instruction of the supplier (Life Technologies). Actin was used as an internal control. RT-PCR was performed for 31 cycles (1 minute/annealing) for each primer, except for CAIX that was performed for 34 cycles. Primer sequence and PCR parameters are reported in Table S3.

#### Luciferase Assay

SLUGLuc, containing the  $-800/+10$  bp SLUG promoter sequence in the pGL3 basal vector, was kindly provided by Dr. Togo Ikuta (Saitama Cancer Centre, Saitama, Japan). ER $\alpha$ Luc plasmid, which contains 3 copies of estrogen response element (ERE), was kindly provided by Dr. Rakesh Kumar (Department of Molecular and Cellular Oncology, MD Anderson Cancer Center, Houston, Texas). CAIXLuc, containing the  $-179/+34$  bp promoter sequence of CAIX, was provided by J Pastorek (Slovak academy of science, Bratislava). Hypoxia responding element (HRE-Luc), containing 3 copies of HIF1 consensus was kindly

provided by Dr. Giovanni Melillo (Tumor hypoxia laboratory, National Cancer Institute, Frederick, MD, USA). IL6Luc, containing the  $-2161$  to  $-41$  bp IL6 promoter sequence, was kindly provided by Dr. WL Farrar (NCI-Frederick Cancer Research and Development Center, Frederick, MD, USA). PPRELuc, containing 7 copies of PPARs consensus, was kindly provided by Professor Ronald Evans (Salk Institute, La Jolla, CA). NF- $\kappa$ BLuc was previously described [12]. Each of the above plasmids (1  $\mu$ g) were co-transfected with a thymidine kinase promoter driven Renilla luciferase (400 ng) plasmid as a reference control (Promega, USA). MS transfection was performed with JET-PEI reagent (Poly-plus transfection) (3  $\mu$ L for 1  $\mu$ g plasmid) and Luciferase activity was assayed after 48 h using the Dual-Luciferase<sup>®</sup> Reporter Assay System (Promega), according to the manufacturer's instructions. Luciferase activity was normalized over Renilla activity and all reported experiments were performed in triplicates.

#### Western-blot Analysis (WB)

Cell lysates were prepared, run, and blotted as previous described [24] and probed with specific antibodies: rabbit polyclonal anti-PPAR $\gamma$  (Pierce, Rockford, MD, USA), mouse monoclonal anti-ApoE (Origene, Rockville, MD, USA), anti-PPAR $\alpha$  (Thermoscientific, Rockford, MD, USA), anti-CAIX (clone M-75, kindly provided by Jaromir Pastorek, Slovak academy of science, Bratislava), anti-HIF1 $\alpha$  (Pierce, USA), anti-actin (SantaCruz, USA). Protein levels were detected by direct acquisition of chemiluminescence in an imager (ChemiDoc XRS, Bio-Rad, Milan, Italy) by luminol (Millipore, USA) and were quantified in triplicates using a densitometric image analysis software (Quantity One 4.6, Bio-Rad, Milan, Italy).

#### Elisa Test

Determination of TNF $\alpha$  and TGF $\beta$  level in TAF and NAF supernatant were evaluated by ELISA (S.I.C., Rome, Italy). Briefly, cells were seeded in a 6-well plate at the density of  $3 \times 10^5$  cells per well and collected in serum-free medium for 24 h. The harvested medium was centrifuged at  $500 \times g$  for 5 min (4°C) to remove floating cells and the supernatants were collected and assayed following the customer's instructions.

#### Statistical and Bioinformatic Analysis

Statistical significance was assessed by ANOVA followed by Bonferroni's multiple comparison test or two-tail Student's t-test, as appropriate, using PRISM 5.1 (Graphpad Software, La Jolla, CA, USA). The level for accepted statistical significance is  $p < 0.05$ . mRNA 3'-UTR were analyzed for miRNA binding site by the online software Targetscan (www.Targetscan.com).
