23 ABSTRACT

Marek's disease (MD) is an important lymphoproliferative disease of chickens, caused by Gallid 24 alphaherpesvirus 2 (GaHV-2). Outbreaks are commonly reported in commercial flocks, but also in 25 backyard chickens. While the molecular characteristics of GaHV-2 strains from the commercial 26 poultry sector have been reported, no recent data are available for the rural sector. To fill this gap, 27 19 GaHV-2 strains detected in 19 Italian backyard chicken flocks during suspected MD outbreaks 28 were molecularly characterized through an analysis of the *meg* gene, the major GaHV-2 oncogene. 29 30 The number of four consecutive prolines (PPPP) within the proline-rich repeats of the Meq transactivation domain, the proline content and the presence of amino acid substitutions were 31 32 determined. Phylogenetic analysis was performed using the Maximum Likelihood method. Sequence analysis revealed a heterogeneous population of GaHV-2 strains circulating in Italian 33 backvard flocks. Seven strains, detected from birds affected by classical MD, showed a unique *mea* 34 isoform of 418 amino acids (aa) with a very high number of PPPP motifs. Molecular and clinical 35 features are suggestive of a low oncogenic potential of these strains. The remaining 12 strains, 36 detected from flocks experiencing acute MD, transient paralysis or sudden death, had shorter Meq 37 protein isoforms (298 or 339 aa) with a lower number of PPPP motifs and point mutations 38 interrupting PPPPs. These features allow us to assert the high virulence of these strains. These 39 40 findings reveal the circulation of low and high virulence GaHV-2 strains in the Italian rural sector. 41 Key words: backyard chicken; Marek's disease virus; meg gene; molecular characterization 42 43

INTRODUCTION

Marek's disease (MD) is a worldwide, contagious, lymphoprolipherative disease of chickens caused 50 by a lymphotropic and oncogenic virus, *Gallid alphaherpesvirus 2* (GaHV-2); it is also known as 51 52 Marek's disease virus, belonging to the genus Mardivirus of the Alphaherpesvirinae subfamily. Genus Mardivirus includes two other viral species: Gallid alphaherpesvirus 3 (GaHV-3) and 53 Meleagrid alphaherpesvirus 1 or Turkey herpesvirus (HVT). GaHV-3 and HVT are both non-54 oncogenic and used as vaccines, being antigenically related to GaHV-2. Four GaHV-2 pathotypes 55 are currently recognized: mild, virulent, very virulent and very virulent plus (Witter, 1997; Witter et 56 al., 2005). Birds become infected by inhalation of infectious viral particles that are present in the 57 58 environment. GaHV-2 is capable of replicating and establishing latency in T lymphocytes and may induce neoplastic transformation of latently-infected CD4+ T cells, leading to the development of 59 multiple lymphomas in the visceral organs (Nair, 2013). GaHV-2 causes several pathologic 60 syndromes, which can be divided into two types: neoplastic and nonneoplastic (Gimeno, 2014). 61 Neoplastic syndromes, characterized by GaHV-2-induced lymphoproliferative lesions, are the most 62 63 frequently reported syndromes in the field, having prominent economic significance. Within this category, MD can be subdivided into two forms: classical and acute. Classical MD (also known as 64 fowl paralysis) is characterized by spastic paralysis due to nerve lesions; it was mainly observed 65 66 prior to the 1950s, concomitantly with infection with low virulence strains (Witter, 1997). The more severe form of the disease, termed acute MD (Biggs et al., 1965), was observed from the late 1950s 67 and is characterized by visceral lymphomas, with or without nerve lesions, and associated with 68 infection with more virulent GaHV-2 strains (Witter, 1997). Nonneoplastic syndromes, such as 69 transient paralysis, panophthalmitis, atherosclerosis and lymphodegenerative syndromes, are rare in 70 the field as they normally occur in unvaccinated, susceptible chickens without specific maternally-71 derived antibodies (Gimeno, 2014). 72

Among the more than 200 genes of the GaHV-2 genome, the Marek's *Eco* RI-Q (*meq*) gene, unique
to GaHV-2 and highly expressed in latently-infected and transformed T CD4+ cells (Tai et al.,

2017), is proposed to play a key role in the GaHV-2-induced transformation process of latently-75 infected T lymphocytes. The meg gene encodes the Meq protein, a basic leucine zipper transcription 76 factor composed of an N-terminal basic leucine zipper (**bZIP**) domain and a proline-rich C-terminal 77 78 transactivation domain (Qian et al., 1995). The last 33 carboxy-terminal amino acids are essential for transcriptional transactivation (Qian et al., 1995), whereas the number of proline-rich repeats 79 (PRR) in the transactivation domain seems to be related with repression of transcription (Chang et 80 al., 2002a). Meg is a polymorphic gene, with various recognized sizes: long-meg (L-meg), meg, 81 82 short-meq (S-meq) and very short-meq (VS-meq); these encode Meq protein isoforms with 399, 339, 298 and 247 amino acids, respectively (Chang et al., 2002b). The existence of these different 83 84 length Meg isoforms is due to the presence of insertions or deletions in the transactivation domain, resulting in a variable number of PRR. This number, along with specific point mutations in the 85 PRR, appears to correlate with GaHV-2 virulence (Shamblin et al., 2004; Renz et al., 2012). 86 Moreover, the *meq* gene has been recently included in a list of candidate genes associated with an 87 increase of GaHV-2 virulence due to a greater-than-average number of point mutations found in the 88 virulent Eurasian and North American GaHV-2 strains (Trimpert et al., 2017). This gene is evolving 89 at a fast rate for a dsDNA virus, and most of its polymorphisms have evolved under positive 90 selection (Padhi and Parcells, 2016). 91

92 MD is a major cause of mortality in backyard chickens (Pohjola et al., 2015; Mete et al., 2016) and GaHV-2 strains can circulate freely because flocks composed of birds with different immune 93 statuses, ages and breeds, are more susceptible to infection. Backyard farm owners do not generally 94 95 vaccinate their birds and backyard production methods imply a low biosecurity level (Cecchinato et al., 2011); this facilitates the circulation of infectious agents, including GaHV-2, and constitutes a 96 threat to any commercial poultry holdings nearby. To our knowledge, recent data about molecular 97 characteristics of Marek's disease virus circulating in backyard flocks worldwide is not available. In 98 the present study, we analyzed the complete meg gene sequences of 19 GaHV-2 strains detected 99 from suspected MD outbreaks in 19 Italian backyard chicken flocks. 100

MATERIALS AND METHODS

101

102 Backyard Flocks

From 2015 to 2017, 19 Italian backyard chicken flocks were sampled for routine molecular
diagnostic activity for MD. All flocks were unvaccinated for MD and showed clinical signs or
lesions suggestive of MD. Several chicken breeds were involved in the outbreaks (Table 1). The
farms were located in nine different Italian regions (Table 1) and consisted of a variable number of
chickens (from 40 to 150), kept mainly for exhibition or hobby and marginally for eggs and meat.
Other poultry species, such as turkey, quail, peacock, pigeon, goose, duck, guinea fowl and Roul
Roul partridge, were reared alongside the affected chickens on most farms.

110

111 Sampling

For GaHV-2 PCR detection, five feathers/bird were collected from the axillary feather tracts, as suggested by Baigent et al. (2013). Feather sampling was chosen because it is easy, fast, noninvasive and non-lethal (Davidson et al., 2018), and is suitable for sampling ornamental chicken breeds that have economic and emotional value.

116

117 DNA Extraction

Total DNA was extracted from feather tips using a commercial kit (High Pure PCR Template
Preparation Kit, Roche Diagnostics GmbH, Mannheim, Germany), with a subtle adjustment to the
manufacturer's instructions. Briefly, five feather tips from each bird were pooled together, cut,
ground and digested overnight at 55°C in a digestion buffer containing tissue lysis buffer,
proteinase K and DL-Dithiothreitol solution (Sigma-Aldrich, Saint Louis, Missouri, USA). After
digestion, binding buffer followed by isopropanol was added and samples were placed in spin

124 columns and centrifuged at 8000 \times g for 1 min. After two washings, DNA was eluted with 200 µl of

elution buffer.

127 PCR Amplification of the *meq* Gene

The full-length meg gene was amplified, according to Shamblin et al. (2004), using the forward 128 primer EcoR-Q for 5'-GGT GAT ATA AAG ACG ATA GTC ATG-3' and the reverse primer 129 130 EcoR-Q rev 5'-CTC ATA CTT CGG AAC TCC TGG AG-3'. In a total reaction volume of 25 µl, 3 µl of eluted template DNA was mixed with 0.125 µl of GoTag G2 Flexi DNA Polymerase 131 (Promega, Madison, Wisconsin, USA), 5 µl of 5X Colorless GoTaq Flexi Buffer, 1.75 µl of MgCl₂ 132 solution, 0.5 µl of dNTPs, 13 µl of H₂O for molecular biology, and 1 µl of each primer. Cycling 133 conditions were as follows: 2 min of denaturation at 95°C followed by 35 cycles, each consisting of 134 denaturation at 95°C for 1 min, annealing at 58°C for 1 min and extension at 72 °C for 1.5 min. A 135 136 final elongation step at 72 °C for 5 min completed the reaction. The PCR products were separated on agarose gel (1%), stained with ethidium bromide and visualized under ultraviolet light after an 137 electrophoretic run at 80Vand 400mA for 50 min. 138

139

140 DNA Sequencing and Sequence Analysis

The amplification products were sequenced using a commercial sequencing service (Macrogen
Europe, Amsterdam, The Netherlands). In order to obtain a complete and reliable *meq* gene
sequence, primers *Eco*R-Q for, *Eco*R-Q rev (Shamblin et al., 2004) and an internal primer (*meq*-F,
5'-ATG TCT CAG GAG CCA GAG CCG-3') (Hassanin et al., 2013) were used. The obtained
sequences were named using the following nomenclature: GaHV-2 / Italy / Chicken (Ck) / ID
number / year of detection.

147 The nucleotide sequences were assembled and edited using Bioedit Sequence Alignment Editor

148 Version 7.2.5.0 (Tom Hall, Ibis Therapeutics, Carlsbad, California, USA), then, aligned and

149 compared, using Clustal W software (Thompson et al., 1994), with the *meq* gene sequences of 32

selected GaHV-2 field and vaccine strains retrieved from the GenBank database (Table 2) and with

- the sequences of three CVI988/Rispens vaccine strains currently used in Italy. The number of four
- 152 consecutive prolines (**PPPP**) contained in the proline-rich repeats of the transactivation domain, the

proline content and the amino acid (aa) substitutions in the deduced aa sequence of *meq* genes wereevaluated.

A phylogenetic tree based on the *meq* gene sequences of Italian and selected GaHV-2 strains from

156 GenBank was generated with the Maximum Likelihood method, using MEGA7 (Kumar et al.,

157 2016). Only the nodes of the tree with bootstrap values equal or greater than 70, calculated based on

158 1000 replicates, were considered reliable.

- 159
- 160

RESULTS

All 19 backyard chicken flocks tested in the present study were positive for GaHV-2. The obtained
complete *meq* gene sequences were submitted to the GenBank database under the accession
numbers listed in Table 3. Sequence analysis revealed that GaHV-2 strains had *meq* gene sequences
of variable sizes: 1257 bp, 1020 bp or 897 bp, which were named "very long *meq*", "standard *meq*"
and "short *meq*" strains, respectively, based on a slightly modified version of the *meq* open reading
frames classification reported by Chang et al. (2002b) (Table 3).

Length, insertion size, number of PPPP motifs within the transactivation domain and the proline 167 content of meg deduced amino acid sequences of the Italian GaHV-2 strains and one representative 168 GaHV-2 strain for each pathotype were evaluated (Table 4). Seven GaHV-2 strains showed a long 169 Meq isoform (418 aa, "very long *meq*" strains), with an insertion of 79 amino acids and a high 170 number of PPPP motifs (9–10). Eleven strains had a short Meq isoform (339 aa, "standard meq" 171 strains) without insertion in the transactivation domain and a lower number of PPPPs (4-5). Only 172 one strain showed a very short Meq isoform (298 aa, "short meq" strain) with two PPPPs in its 173 transactivation domain. 174

175 The amino acid substitutions found in the Meq proteins of the analysed strains compared to the

vaccine strain CVI988 (Intervet), chosen as reference strain, are reported in Tables 5, 6 and 7.

177 Sequences of "very long *meq*" strains, which differ among themselves with respect to very few

amino acid changes, showed 10 to 14 amino acid substitutions when compared with the CVI988

vaccine strain. Five of these mutations, at positions 37 (H37R), 80 (D80E), 98 (H98D), 101

180 (K101N), and 242 (F242I) of the Meq protein (Table 5), were only found in the Italian strains. The

uniqueness of this mutation pattern was further confirmed by a BLAST search. Five to eight amino

acid substitutions were found when "standard *meq*" (Table 6) and "short *meq*" (Table 7) strains

183 were compared with the CVI988 vaccine strain. Almost all amino acid changes of "standard *meq*"

and "short meq" strain-encoded Meqs have already been reported in previously published

185 International sequences.

186 "Standard *meq*" and "short *meq*" strains contained interruptions of PPPP motifs in the PRR of the

187 transactivation domain, both at the second and third position. In particular, the GaHV-

188 2/Italy/855/17 strain showed a substitution at position 177 (P177S), interrupting a stretch of four

prolines at position 3 (PPPP \rightarrow PPSP). The GaHV-2/Italy/Ck/674/16 strain showed a substitution at

position 217 (P217A), interrupting a PPPP sequence at position 2 (PPPP \rightarrow PAPP). Finally, the

191 strains GaHV-2/Italy/Ck/625/16, GaHV-2/Italy/Ck/689/16, GaHV-2/Italy/Ck/722/16, GaHV-

192 2/Italy/Ck/801/16, GaHV-2/Italy/Ck/810/16, GaHV-2/Italy/Ck/852/16, GaHV-2/Italy/Ck/853/16

and GaHV-2/Italy/Ck/854/16 showed substitutions at position 218 (P218S), interrupting the PPPP

194 sequence at position 3 (PPPP \rightarrow PPSP).

195 The phylogenetic tree, based on the Meq amino acid sequences of the Italian strains, the vaccine

strains and 32 selected GaHV-2 strains, is shown in Figure 1. The "very long *meq*" Italian strains

197 form an independent cluster, phylogenetically related to a cluster formed by Hungarian and Indian

198 strains. Nine out of eleven Italian "standard *meq*" strains and the "short *meq*" strain clustered

together with selected Polish isolates. Two Italian "standard meq" strains (GaHV-2/Italy/Ck/674/16

and GaHV-2/Italy/Ck/850/17) did not belong to the above-mentioned group and the GaHV-

201 2/Italy/Ck/674/16 strain appeared to be connected with a recent Tunisian strain.

202

203

DISCUSSION

For the first time, the present study provides molecular insights into the GaHV-2 strains currently circulating in backyard chickens, expanding the knowledge on MD in the rural sector. Nineteen strains, detected from 2015 to 2017 in Italian backyard chickens exhibiting typical MD clinical signs or gross lesions, were molecularly characterized on the basis of their *meq* gene sequences, revealing the circulation of a heterogeneous viral population.

Previous studies highlighted a correlation between the *meq* gene sequence and GaHV-2 virulence
(Shamblin et al., 2004; Renz et al., 2012). In particular, strains showing a low number of PRR
within the transactivation domain, and amino acid substitutions interrupting PPPP motifs within the
PRR, exhibit higher virulence. In the sequence analysis, the Italian strains were subdivided,
according to *meq* gene length, into three categories: "very long *meq*", "standard *meq*" and "short *meq*".

The "very long meq" strains detected in the present study showed a Meq isoform of 418 aa with a 217 high number (from 9 to 10) of PPPP motifs in their transactivation domains. These molecular 218 features could be suggestive of low oncogenic potential. Moreover, all "very long meq" strains were 219 detected from birds affected by classical MD, macroscopically not showing visceral tumours and 220 experiencing a complete recovery in three out of seven outbreaks. These strains share diverse and 221 sometimes unique aa substitutions that, in part (H98D, K101N and Q93R), fall within the bZIP 222 domain. This domain is responsible for Meq dimerization with itself or with other dimerization 223 partners, forming homodimers or heterodimers, respectively. The ability to form one interaction or 224 the other is influenced by the bZIP sequence and the presence of mutations in this domain could 225 disrupt the formation of one or both types of dimers (Brown et al., 2009; Suchodolski et al., 2009; 226 227 Suchodolski et al., 2010). This interaction allows the adjacent basic region of Meq to anchor to specific DNA binding sites with different affinities, depending on the dimer type, consequently 228 transactivating or transrepressing viral and host genes exerting different biological effects, mostly 229 linked to oncogenesis (Qian et al., 1996; Liu et al., 1998; Levy et al., 2005). The three amino acid 230

substitutions found in the bZIP domain might have altered the Meq binding capacity and

contributed to the low oncogenicity of the Italian "very long *meq*" strains.

On the other hand, "standard *meq*" and "short *meq*" strains were detected from flocks experiencing acute MD, transient paralysis or sudden death, occasionally preceded by neurologic signs. These also featured a low number of PPPP motifs in the transactivation domain, and the presence of point mutations in the PRR that interrupted stretches of four prolines in most of the "short *meq*" or "standard *meq*" strains; this allows us to assert, according to Shamblin et al. (2004), the high virulence of these strains. These findings reveal the circulation of both low and high virulence GaHV-2 strains in the Italian rural sector.

The variability of observed MD clinical forms could be also due to different disease susceptibilities amongst the different breeds involved. Genetic resistance to MD is well known and while breeding programs for commercial poultry generally include genetic selection for resistance to MD (Schat and Nair, 2013), selection programs for ornamental chickens are mainly focused on the selection of phenotypic traits compliant with the breed standard.

The heterogeneity of the viral population, supported by the allocation of the analyzed strains into three major clusters, suggests that the introduction of GaHV-2 to Italy could have occurred over multiple occasions. Ornamental chicken owners regularly enter their birds into international 'beauty contests', where chickens are generally kept in adjacent cages, facilitating the transmission of the virus from bird to bird. The national and international trade of live, valuable breeders is another possible route of entry.

Viruses could also have reached the rural context by overcoming the biosecurity measures applied in commercial poultry houses to find a highly variable poultry population with different species, breeds, ages and immune statuses, with unknown susceptibility to MD. The reverse could be also true: backyard flocks could act as reservoir for GaHV-2 strains of various and unknown pathotypes, representing a potential threat for commercial poultry flocks located in the same area. Biosecurity measures are not generally applied to backyard farms (Cecchinato et al., 2011) and, in most cases,

257	birds have continuous daytime access to open-air pens, and contact with wild birds; these birds have
258	been identified as carriers of presumably pathogenic GaHV-2 strains (Murata et al., 2012), so this
259	may facilitate the introduction of foreign viruses.

- 260 Finally, the last detections of low virulence viruses dates back to the 1970s (Smith and Calnek,
- 1973; Smith and Calnek, 1974), presumably because of the poultry industry's major interest in
- 262 investigating highly virulent strains responsible for MD outbreaks in vaccinated commercial poultry
- flocks (López-Osorio et al., 2017; Suresh et al., 2017; Abd-Ellatieff et al., 2018). Weakly virulent
- viruses are more likely to circulate naturally in backyard flocks, probably due to the absence of
- 265 vaccine-induced selective pressure and weak biosecurity measures.

Molecular characterization and clinical findings are not sufficient to ascertain the level of virulence of the detected viruses, therefore, in vivo pathotyping assays are needed. For this purpose, viral isolation should be attempted. Moreover, the isolation of weakly virulent strains could offer the opportunity to evaluate their potential as candidate vaccines.

Table 1. Geographical location of the studied backyard flocks, with the observed clinical forms of Marek's disease (MD) and the age and breed of affected chickens.

¹Birds experienced a complete recovery;

²Clinical signs and gross lesions were not specific for MD. High mortality is often reported.
