16 **Abstract:** Higher systematics within the Digenea, Carus 1863 have been relatively stable since a  
17 phylogenetic analysis of partial nuclear ribosomal markers (rDNA) led to the erection of the  
18 Diplostomida Olson, Cribb, Tkach, Bray, and Littlewood, 2003. However, recent mitochondrial  
19 (mt) genome phylogenies suggest this order might be paraphyletic. These analyses show  
20 members of two diplostomidan superfamilies are more closely related to the Plagiorchiida La  
21 Rue, 1957 than to other members of the Diplostomida. In one of the groups implicated, the  
22 Diplostomoidea Poirier, 1886, a recent phylogeny based on mt DNA also indicates the  
23 superfamily as a whole is non-monophyletic. To determine if these results were robust to  
24 additional taxon sampling, we analyzed mt genomes from seven diplostomoids in three families.  
25 To choose between phylogenetic alternatives based on mt genomes and the prior rDNA-based  
26 topology, we also analyzed hundreds of ultra-conserved elements (UCEs) assembled from  
27 shotgun sequencing. The Diplostomida was paraphyletic in the mt genome phylogeny, but  
28 supported in the UCE phylogeny. We speculate this mitonuclear discordance is related to  
29 ancient, rapid radiation in the Digenea. Both UCEs and mt genomes support the monophyly of  
30 the Diplostomoidea and show congruent relationships within it. The Cyathocotylidae Mühling,  
31 1898 are early diverging descendants of a paraphyletic clade of Diplostomidae Poirier, 1886, in  
32 which were nested members of the Strigeidae Railliet, 1919; the results support prior suggestions  
33 that the Crassiphialinae Sudarikov, 1960 will rise to the family level. Morphological traits of  
34 diplostomoid metacercariae appear to be more useful for differentiating higher taxa than those of  
35 adults. We describe a new species of *Cotylurus* Szidat, 1928, resurrect a species of  
36 *Hysteromorpha* Lutz, 1931, and find support for a species of *Alaria* Schrank, 1788 of contested  
37 validity. Complete rDNA operons are provided as a resource for future studies.

38 **Keywords:** Strigeida, Diplostomida, Phylogenomics, Metacercaria, Nuclear-mitochondrial  
39 discordance, *Cotylurus*, *Hysteromorpha*, *Alaria*

40

## 41 **1. Introduction**

42 Early efforts to organize the higher taxonomy of digenetic trematodes relied mainly on  
43 external morphology of adults (reviewed by La Rue, 1957). As life cycles became better known,  
44 Cort (1917), Stunkard (1946) and others increasingly emphasized other characters, particularly  
45 cercarial morphology. Using a variety of methods, different authors produced conflicting  
46 hypotheses and higher classifications, but many concluded a close relationship exists among  
47 members of the Diplostomoidea Poirier, 1886, the Clinostomatoidea Lühe, 1901, and the  
48 Schistosomatoidea Stiles and Hassall, 1898 (Brooks et al., 1985; Dubois, 1970a; Gibson, 1996;  
49 La Rue, 1957; Pearson, 1972). Most authors assigned these and other superfamilies to the  
50 Strigeida (=Strigeatoidea) La Rue 1957, which are characterized by furcocercous cercariae that  
51 penetrate hosts (Gibson and Bray, 1994). The close relationship among strigeids, clinostomes  
52 and schistosomes was supported by a phylogenetic analysis of partial nuclear ribosomal markers  
53 (rDNA) from digeneans in 77 families (Olson et al., 2003). In this analysis, however, several  
54 other families in the Strigeida fell within the Plagiorchiida La Rue, 1957, leading Olson et al.  
55 (2003) to erect the order Diplostomida, which now includes diplostomoids, clinostomatids, and  
56 schistosomatoids.

57 The work of Olson et al. (2003) created stability in higher systematics within the Digenea.  
58 For example, the subsequent studies and future research directions discussed by Kostadinova and  
59 Pérez-del-Olmo (2014) are mainly limited to intra-ordinal relationships. However, recent work  
60 raises questions about the status of the Diplostomida (Fig. 1). Separate phylogenetic analyses of  
61 mt genomes show two diplostomidans (*Clinostomum* Leidy, 1856, *Diplostomum* von Nordmann,  
62 1832) are more closely related to the Plagiorchiida than to other members of the Diplostomida  
63 (Brabec et al., 2015; Briscoe et al., 2016; Chen et al., 2016; see also Fig. 5 in Park, 2007). Brabec

64 et al. (2015) argued that data from additional taxa are needed before biological and taxonomic  
65 implications can be judged. However, it is well to note that the mt phylogenies were based on  
66 alignments of considerably more characters than the rDNA phylogeny of Olson et al. (2003).  
67 Moreover, mt genome analyses now collectively include two of three diplostomidan  
68 superfamilies, and statistical support for the alliance of non-schistosome diplostomidans with the  
69 Plagiorchiida has increased with increased taxon sampling (support of the key nodes of 0.77 in  
70 Brabec et al., 2015; 1.0 in Chen et al., 2016; 0.93 in Briscoe et al., 2016). More generally,  
71 mtDNA has been useful in revealing ordinal relationships in other Platyhelminthes  
72 (Waeschenbach et al., 2012). Further evaluation of this discordance (Fig. 1) was one of two goals  
73 of our study.

74 Another was to estimate relationships among members of one superfamily in the  
75 Diplostomida, the Diplostomoidea, which are characterized by the tribocytic organ, a holdfast  
76 absent in other digeneans. Six families recognized or erected by Dubois (1938, 1970b) are in  
77 wide use, although problems with these classifications are often noted. Shoop's (1989) cladistic  
78 analysis indicated the Diplostomidae Poirier, 1886 was paraphyletic. Both Shoop (1989) and  
79 Niewiadomska (2002a) agreed that the morphological type of the metacercaria appears to reflect  
80 higher relationships in the Diplostomoidea, but the higher classifications of Dubois (1938,  
81 1970b), based largely on the class of hosts and morphology adults, did not take this into account.  
82 Most molecular phylogenetic studies indicate the superfamily is monophyletic, but find the two  
83 largest families, the Strigeidae Railliet, 1919 and Diplostomidae, are not (Blasco-Costa and  
84 Locke, 2017; Dzikowski et al., 2004; Olson et al., 2003). One analysis of partial cytochrome *c*  
85 oxidase 1 (CO1) recovered the Cyathocotylidae Mühling, 1898 (Diplostomoidea) within the

86 Schistosomatoidea (Hernández-Mena et al., 2017), which suggests even the superfamily could be  
87 non-monophyletic.

88 Two obstacles currently prevent molecular assessment of higher taxonomy within the  
89 Diplostomoidea, its position within the Digenea, and implications for the order Diplostomida.  
90 The first is poor taxonomic and geographic coverage (Blasco-Costa and Locke, 2017). Recent  
91 work is encouraging, with studies including members of the Proterodiplostomidae Dubois, 1936  
92 (Hernández-Mena et al., 2017), Brauninidae Wolf, 1903 and Cyathocotylidae (Blasco-Costa and  
93 Locke, 2017; Fraija-Fernández et al., 2015), and less well-sampled regions (Blasco-Costa et al.,  
94 2016; Chaudhary et al., 2017; López-Hernández et al., 2018; Sereno-Uribe et al., 2018).

95 Another issue is that accumulating molecular data may not be sufficiently rich in  
96 characters to resolve higher relationships. Most analyses of intra-diplostomoid relations are  
97 based on sequences of DNA from one or two loci totalling less than 2000 bp in length (e.g.,  
98 Blasco-Costa and Locke, 2017, and references therein). This seems sufficient for specimen  
99 identification, discrimination of species, and species membership in genera (e.g., Chibwana et al.  
100 2013; Locke et al. 2015; López-Hernández et al., 2018), but relationships among genera and  
101 families are less resolved. For example, there is inconsistency and often little support in the  
102 polarity among *Alaria*, *Apharyngostrigea*, and *Cardiocephaloides* in fig. 3 in Olson et al. (2003),  
103 fig. 1 in Fraija-Fernández et al. (2015), and fig. 2 in Hernández-Mena et al. (2017), which are all  
104 phylogenies based on concatenated sequences of rDNA subunits. The deep conflict between  
105 recent mt genome phylogenies and those based on shorter nuclear DNA sequences (Fig. 1) may  
106 also be related to differences in the number of informative characters.

107 Here we attempt to progress on both fronts. We increase the number and diversity of  
108 mitochondrial genomes from the Diplostomoidea, in order to explore discordant results of recent

109 phylogenetic studies, namely the possible placement of the Cyathocotyliidae outside the  
110 Diplostomoidea (Hernández-Mena et al., 2017), and the Diplostomidae as a basal lineage in the  
111 order Plagiorchiida (Brabec et al., 2015). Both results originate from analysis of mtDNA, and we  
112 obtained data to determine if these patterns were robust to additional taxon sampling. To decide  
113 between what were likely to be conflicting topologies based on mtDNA and rDNA, we  
114 employed phylogenomic analyses of ultra-conserved elements (UCEs).

115         Although we set out to work on higher relationships among a small number of  
116 representative specimens, we were aware that the diversity and identity of diplostomoid species  
117 often differs from initial suspicions based on morphology (Blasco-Costa and Locke, 2017). We  
118 therefore supported our identifications with morphological comparisons and analysis of  
119 additional DNA sequences from closely related species, which led to several findings related to  
120 the alpha taxonomy of the seven specimens of principal interest.

121

## 122 **2. Materials and Methods**

### 123 *2.1 Specimen collection and identification*

124         Twenty-five specimens in good condition were selected for potential Illumina shotgun  
125 sequencing (described below). These worms had been stored in ethanol and identified to genus,  
126 and were chosen to represent major clades in Blasco-Costa and Locke (2017). DNA was  
127 extracted from individual worms, or subsamples, using Qiagen's DNEasy blood and tissue kit  
128 (GmbH, Germany), following the manufacturer's protocol with two 200- $\mu$ L elutions. Of these 25  
129 worms, we selected seven (Table 1) after measuring DNA concentration with Nano-drop (0.5-22  
130 ng/ $\mu$ l in 400  $\mu$ l) and Qubit (0-4.96 ng/ $\mu$ l) and excluding samples with evidence of DNA  
131 degradation (Bioanalyzer).

132 Additional conspecific or closely related parasites that contributed to identification of the  
133 seven worms, or constituted relevant host or geographic records, were processed  
134 morphologically and with PCR and Sanger sequencing (see below). Morphological vouchers  
135 were cleared in Amman's lactophenol, rehydrated, stained in dilute acetocarmine, dehydrated in  
136 ethanol, cleared in clove oil, and mounted on a slide in Canada balsam. Vouchers comprised  
137 hologenophores (DNA sequenced from the worm studied morphologically), paragenophores  
138 (similar worms from the same individual host paired for either morphological or molecular  
139 work) and syngenophores (voucher worms from different host individuals collected at the same  
140 time, or on other occasions, or in the same region, as the worms from which DNA was extracted)  
141 (Pleijel et al., 2008). Drawings and measurements were made with the aid of a camera lucida and  
142 ocular micrometer.

## 143 *2.2 Molecular and phylogenetic analysis*

144 Seven samples were processed on a single lane of an Illumina HiSeq 4000 and 150-bp  
145 paired-end libraries were built using Illumina TrueSeq adapters at the UC Davis Genome Center.  
146 Partial CO1 barcodes were obtained using the primers and PCR protocols of Moszczyńska et al.  
147 (2009) and Sanger sequencing, from the seven worms or other representatives, and were used to  
148 seed iterative assemblies of Illumina reads of whole mitochondrial genomes, using Geneious V9.  
149 Mitochondrial genomes were annotated in MITOS (Bernt et al., 2013) using NCBI's Echinoderm  
150 and Flatworm Mitochondrial translation table (number 9). Additional annotations, including  
151 minor modifications to MITOS output, were made using alignments with mitochondrial genomes  
152 from two species of *Diplostomum* (Brabec et al., 2015) (KR269763-4), *Clinostomum*  
153 *complanatum* (KM923964), *Fasciola hepatica* (NC\_002546.1), *Trichobilharia regenti*  
154 (NC\_009680.1), and *Schistosoma japonicum* (NC\_002544.1). A similar approach was taken to

155 assemble complete rDNA operons (18S, ITS1, 5.8S, ITS2, and 28S). Illumina reads were  
156 mapped to rDNA sequences from, in some cases, the same samples or other representatives  
157 obtained using primers in Galazzo et al. (2002); Olson et al. (2003), and in other cases, using  
158 previously published sequences from the same species or close relatives (GB ACCESSIONS  
159 XXXXXX).

160 The seven mitochondrial genomes were analyzed with previously published data from Digenea  
161 and Eucestoda. Protein-coding regions were extracted and placed in the same order (i.e.,  
162 *atp6+nad2* and *nad3* were placed before and after *nad1*, respectively in *Schistosoma*  
163 *haematobium*, *S. spindale*, and *S. mansoni*, in which the order of these genes differs). Protein-  
164 coding regions were concatenated, and both nucleotide and translated into amino acid sequences  
165 were aligned using MAFFT (L-INS-I). Alignments were stripped of columns with gaps and  
166 analyzed with RAXML (Silvestro and Michalak, 2012; Stamatakis, 2014) using a substitution  
167 model selected with the Bayesian Information Criterion (Tamura et al., 2013).

168 For UCE work, quality trimming was conducted with *bbduk* from the *BBDMap* package  
169 (Bushnell, 2014). *De novo* genomes were assembled for each sample with *IDBA-Hybrid* (Peng  
170 et al., 2012) using *Schistosoma mansoni* (GCF\_000237925.1) to help scaffold similar regions.  
171 The quality of *de novo* assemblies was assessed with *BUSCO* (Simão et al., 2015). Conserved  
172 genomic regions across were identified using *PHYLUCES* v1.6 (Faircloth, 2016). Trimmed reads  
173 were aligned to the *S. mansoni* genome using *stampy-1.0* (Lunter and Goodson, 2011) with a  
174 substitution rate set to 0.05 to capture overlapping regions with trimmed data. Using overlapping  
175 regions from the *S. mansoni* genome, an initial probe set was mapped back to the *de novo*  
176 genomes via *PHYLUCES* scripts. Genomes were similarly analyzed from *Clonorchis sinensis*

177 (PRJDA72781), *Echinostoma caproni* (PRJEB1207), *Diphyllbothrium latum* (PRJEB1206),  
178 and *Fasciola hepatica* (PRJEB6687).

179 Complete probe sets were generated for ten out of twelve species  
180 (phyluce\_probe\_query\_multi\_fasta\_table in PHYLUCES), with 801 loci and 16,671  $3 \times$  tiling  
181 probes post-duplicate-filtering. Loci were aligned using MAFFT and with 90% matrix  
182 occupancy, 517 loci were retained. The MAFFT-Gblocks option was called in PHYLUCES to  
183 remove poorly aligned regions. Phylogenetic reconstructions were computed using RAxML  
184 (Stamatakis, 2014) from a concatenated matrix with GTRGAMMA substitution rate, with 1,000  
185 bootstrap replicates in each of 20 parallel runs, and *Diphyllbothrium latum* set as outgroup. The  
186 resulting maximum-likelihood (ML) tree with bootstrap bi-partitions was annotated with  
187 morphological and life-history characters from the Diplostomoidea (supplementary Fig. 1). We  
188 also generated one tree without setting *D. latum* as the outgroup, and another after running  
189 PHYLUCES and RAxML solely with the seven diplostomoids and *S. mansoni* set as outgroup (the  
190 latter yielding 796 conserved genetic elements, and 63,959 variable sites based on 85% matrix  
191 occupancy). In both the latter cases (not shown), the topology obtained was well supported and  
192 indistinguishable from the UCE tree reported below.

### 193 **3. Results**

#### 194 *3.1 General molecular results*

195 The genomic analysis of seven samples yielded  $7.8 \times 10^8$  150-bp reads, mean  $1.1 \times 10^8$ , range  
196  $2.1 \times 10^7$ – $1.4 \times 10^8$  reads per sample; mean N50=2833 bp, range 542-11122 bp). Below, and in  
197 Table 2, these and other results are broken down by species.

#### 198 *3.2 Phylogenetic analysis of mitochondrial genomes*

199 The mitochondrial genomes were 13,665 – 15,107 bp in length (supplementary Table 1). The 12  
200 coding regions occurred in the same order as in digeneans other than *S. haematobium*, *S.*  
201 *spindale*, and *S. mansoni*. In *C. prussica*, two pairs of tRNA genes were reversed in order  
202 compared with other diplostomoids. One of these reversals, the occurrence of trnN prior to trnP,  
203 is also a feature of *Clinostomum complanatum* (KM923964). The order of three tRNA genes  
204 occurring between *nad6* and *nad5* in *C. medioconiger* differed from that seen in other  
205 diplostomoids, and these genes were positioned adjacent to a 774-bp non-coding span which,  
206 among diplostomoids and *Clinostomum*, was unique to *C. medioconiger*.

207 Phylogenetic analysis of nucleotide or translated amino acid sequences from the 12 concatenated  
208 coding regions of the mitochondrial genomes did not support the order Diplostomida (Fig. 2).  
209 The diplostomoids and *Clinostomum* emerged as early diverging descendants from common  
210 ancestors of the Plagiorchiida, rather than grouping with *Schistosoma* and *Trichobilharzia*.

### 211 3.3 Phylogenetic analysis of ultra-conserved elements (UCEs)

212 The Diplostomoidea were monophyletic in the topology obtained from ML analysis of 517  
213 conserved genetic elements, comprising 84,902 distinct patterns across 234,783 characters per  
214 taxon (Fig. 3). Consistent with the concept of the Diplostomida and Plagiorchiida, the  
215 Diplostomoidea and *Schistosoma* formed a clade separate from a clade comprising  
216 plagiorchiidans *Clonorchis*, *Echinostoma*, and *Fasciola*.

217 Relationships among diplostomoids were similar to those recovered by analysis of mt genomes,  
218 differing slightly within a clade of Diplostominae *Alaria* + *Hysteromorpha* + *Tylodelphys* +  
219 *Diplostomum* (Figs. 2, 3). Within the diplostomoids, *Cyathocotyle prussica* was basal to a clade

220 in which the Diplostomidae were paraphyletic. The diplostomid *Posthodiplostomum centrarchi*  
221 was basal to a clade of both strigeids and other diplostomids. The two strigeids were sister taxa.  
222 The non-molecular characters of metacercariae showed higher correspondence with the UCE  
223 topology than did the characters of adults (Fig 3, supplementary Fig. 1). Within the  
224 Diplostomoidea all five morphological or life-history characters of metacercariae mapped onto  
225 genomic clades, while correspondence was poorer for adult characters. Metacercarial  
226 apomorphic characters included the structure of the reserve bladder, presence or absence of  
227 encystment, free or enclosed limebodies, and the presence or absence of pseudosuckers, which  
228 distinguished clades comprising relatively small subsets of species. For example, the structure of  
229 the reserve bladder differs among the following four groups, which correspond to clades in the  
230 molecular phylogeny: *Cyathocotyle*, *Posthodiplostomum*, *Cardiocephaloides* + *Cotylurus*, and  
231 *Alaria* + *Hysteromorpha* + *Tylodelphys*. Commonly recognized metacercarial morphotypes  
232 (prohemistomulum, neascus, tetracotyle, diplostomulum) mapped onto all clades formed.

### 233 *3.4 Morphological and molecular support of identification or description of species*

234 Specimens were identified morphologically, and dimensions are reported in  $\mu\text{m}$  and given as  
235 range (means,  $\pm$ standard deviation, n measured). Sequences of partial sequences of cytochrome *c*  
236 oxidase 1 (DNA barcodes) from mitochondrial genomes were also compared to previously  
237 published data and with sequences from additional collections. In a neighbour-joining  
238 phenogram (Fig. 4), CO1 sequences fell into distinct clusters in which the minimum p-distance  
239 between nearest neighbour species was in all cases less than the maximum distance within  
240 species; these clusters formed well supported clades in separate ML analysis. Complete rDNA  
241 operons (Supplementary Table 1) were subjected to BLAST searches, which supported  
242 identifications in all cases, as described further below.

243 3.4.1 *Cyathocotyle prussica* Mühling, 1896

244 *Cyathocotyle prussica* was identified based on morphology of the unstained specimen prior to  
245 DNA extraction, and its provenance (host, geographic origin). Metacercariae of *C. prussica* have  
246 been reported from *Gasterosteus aculeatus* and other small-bodied fishes throughout Europe  
247 (Kalbe et al., 2016; Kvach et al., 2016). The DNA used for genomic work was obtained from a  
248 metacercaria from *Gasterosteus aculeatus* collected at the same time as the specimen sequenced  
249 by Blasco-Costa and Locke (2017) and no morphological voucher remains. The CO1 region of  
250 the mitochondrial genome assembly was 99.7 % (587 / 589 identities) similar to MF124273, and  
251 the rDNA operon 99.1 % (762/769 identities) similar to KY951726, both from Blasco-Costa and  
252 Locke (2017). The rDNA operon differed by 2.5-20.8% from 13 published rDNA sequences  
253 from cyathocotylids on GenBank.

254 3.4.2 *Posthodiplostomum centrarchi* (Hoffman, 1958) Stoyanov, Georgieva, Pankov, Kudlai,  
255 Kostadinova, and Georgiev, 2017 (Fig. 5).

256 [Measurements from 9 specimens (6 paragenophores, 3 hologenophores) ex *Ardea herodias*,  
257 Montreal, Quebec, Canada]

258 Total length 1222–1775; forebody and hindbody separated by marked constriction. Forebody  
259 spatulate 680–1200 long, 452–875 wide, oval to lanceolate, with anterior lateral edges often  
260 recurved ventrally. Hindbody oval, widest in anterior half, tapering posteriorly, 520–875 long,  
261 248–750 wide. Hindbody length / forebody length 0.58–0.86. Oral sucker terminal, 38–72 × 38–  
262 72. Ventral sucker 55–90 × 55–80, in posterior half of forebody, centered 54–71 % along  
263 forebody sagittal axis. Tribocytic organ 140–200 × 144–256. Pharynx 40–53 long, 40–53 wide.  
264 Oesophagus 60–72 long. Ovary lateral to anterior testis at anterior margin of hindbody, 80–105 ×

265 72–88. Testes occupying first 55–80% of hindbody. Anterior testis irregularly, smoothly lobed  
266 96–200 long, 144–272 wide. Posterior testis, sinuous, v-shaped, pointed posteriorly, 176–350  
267 long, 216–350 wide. Vitelline reservoir intertesticular, median. Vitellaria densest at level of  
268 posterior of tribocytic organ and in base of forebody, extending anteriorly beyond ventral sucker  
269 by slightly more than one ventral-sucker length, in hindbody extending more than halfway to  
270 posterior extremity and bifurcating into two posteriorly oriented bands at and beyond vitelline  
271 reservoir, sometimes exceeding, sometimes exceeded by, posterior extent of posterior testis.  
272 Copulatory bursa eversible, terminal or slightly dorsal, 120–216 long, 135–300 wide, housing  
273 muscular genital cone. Eggs few, 0–4, length 70–98 × 42–64 (See supplementary Table 2 for  
274 means, standard deviations, n structures measured).

#### 275 3.4.2.1 Remarks

276 MacCallum (1921) summarily described *Posthodiplostomum (Diplostomum) minimum* from  
277 *Ardea herodias* in New York, USA. Hoffman (1958) created two sub-species, *P. minimum*  
278 *centrarchi* and *P. minimum minimum*, for lineages infecting either centrarchids or cyprinids,  
279 respectively. Stoyanov et al. (2017) elevated the centrarchid subspecies to *P. centrarchi*.

280 Our observations largely agree with Dubois' (1970b) description of the adult (although he did  
281 not distinguish *P. centrarchi* and *P. minimum*), except in the following respects (Supplementary  
282 Table 2): Two of nine specimens were up to 75 greater in total length; in 4/9 specimens, we  
283 observed the hindbody to be widest at the anterior testis (e.g., Fig 5), rather than at the level of  
284 the posterior testis as in Dubois (1970b). The oral sucker was the same length as the pharynx in  
285 1/6 specimens, rather than larger as in Dubois (1970b); the tribocytic organ was wider in 3/6  
286 specimens (200–256 *versus* maximum of 190 in Dubois, 1970b); and in 7/9 specimens the  
287 copulatory bursa was both longer and wider than maximum values (160 × 160) reported by

288 Dubois (1970b). The dimensions of the specimens we encountered also exceed values reported  
289 by Palmieri (1977), who reported means and standard deviations from adults from diverse hosts  
290 experimentally infected with metacercariae from centrarchids. However, as seen above,  
291 morphometric deviations relative to these studies were small, and Palmieri (1977) showed that  
292 adult morphology varies a great deal within *P. centrarchi*. Also, deviations were obtained from  
293 hologenophores genetically matching *P. centrarchi* common in centrarchid hosts (e.g., see  
294 records in (Boone et al., 2018; Locke et al., 2010)), and therefore there is no doubt they represent  
295 *P. centrarchi*.

296 The worm used in genomic analysis had partial CO1 sequences and ITS1-5.8S-ITS2 sequences  
297 99-100% similar to those of *P. centrarchi* (= *Posthodiplostomum* sp. 3 of Locke et al., 2010;  
298 Stoyanov et al., 2017), including the hologenophore in Fig. 5, and CO1 from *P. centrarchi* from  
299 liver of *Lepomis microlophus* in Puerto Rico.

### 300 3.4.3 *Cardiocephaloides medioconiger* Dubois and Viguera, 1949 (Fig. 6)

301 [Measurements from 3 hologenophores ex *Thalassius maximus*, Florida Keys, USA]

302 Total length 7273–8324; forebody and hindbody separated by moderate constriction. Forebody  
303 tulip-shaped 1333–1616 long, 1414–1455 wide. Hindbody 5657–6869 long, 1232–1293 wide,  
304 width gradually increasing posteriorly, widest at level of testes, tapering to point at posterior  
305 extremity. Hindbody 3.5–4.9 as long as forebody. Oral sucker 103–160 × 175–193. Ventral  
306 sucker 103–168 × 112–128. Tribocytic organ bi-lobed, with one lobe well developed and darkly  
307 staining. Pharynx 129–152 long, 119–152 wide. Ovary pretesticular, 363–363 long, 300–363  
308 wide. Vitellaria dense in anterior hindbody, absent from ventral surface in region of ovary and  
309 testes, extending dorsally along anterior of copulatory bursa. Testicular zone 828–1010 long.

310 Anterior testis 303–475 long, 606 wide. Posterior testis 363–484 long, 485–707 wide. Vitelline  
311 reservoir intertesticular. Eggs numerous 94–117 long, 62–70 wide with shells 2.0–2.2 thick.  
312 Copulatory bursa 1010–1919 long. Hindbody length 3.6–5.6 times that of copulatory bursa  
313 (means, standard deviations, n structures measured in Supplementary Table 3).

#### 314 *3.4.3.1 Remarks*

315 *Cardiocephaloides medioconiger* was described from *Larus argentatus* in Cuba and has been  
316 reported from *T. maximus* in the same region (Dubois, 1970b). The morphology of the three  
317 voucher specimens was consistent with Dubois (1970b) (Supplementary Table 3), except that the  
318 following were larger: forebody (maxima of length and width of 1500 and 1360, respectively, in  
319 Dubois, 1970b), oral sucker (maximum width 136 in Dubois, 1970b) and ovary (maximum 278 ×  
320 300 in Dubois, 1970b). The four CO1 barcode sequences obtained were 99.1–99.8% similar to *C.*  
321 *medioconiger* (JX977783) from *Larus* sp. collected in Campeche, Mexico (Hernández-Mena et  
322 al., 2014). Within species of *Cardiocephaloides*, mean variation in CO1 is 0.7% (range 0–1.5%)  
323 and between species, 8.8% (range 7.4–9.7%). The rDNA operon from the specimen we collected  
324 differed by 1.2% (1669/1672 identities) from 18S (MF398359, isolate DNA181) and 2.3% from  
325 the ITS (1041/1065 identities with JX977844, isolate DNA181) of *Cardiocephaloides* sp. from  
326 *Larus occidentalis* in Baja California, Mexico, and by 0.5% (1839/1848 identities) from 18S  
327 from *C. longicollis* (AY222089) from *Larus ridibundus*, Ukraine.

#### 328 *3.4.4.1 Cotylurus marcogliesei* n. sp. (Fig. 7)

#### 329 *3.4.4.2 Description*

330 [Measurements from 11 specimens (3 hologenophores, 7 paragenophores, and holotype), ex

331 *Lophodytes cucullatus*]

332 Adult total length 816–1152 (973±107, 10); forebody and hindbody separated by marked  
333 constriction. Body mildly arched dorsally. Forebody cup-shaped 216–408 (307±51, 11) long,  
334 312–640 (436±95, 10) wide, with broad, oblique opening. Ventral forebody wall markedly  
335 shorter than dorsal. Hindbody stout along entire length, 600–880 (703±96, 10) long, 256–520  
336 (318±81, 9) wide. Forebody to hindbody length ratio 1:1.9–2.8 (2.3±0.3, 10). Oral sucker  
337 terminal, 48–80 (68±13, 9) × 64–112 (85±15, 8). Ventral sucker 64–128 (99±24, 6) × 80–168  
338 (108±28, 7). Tribocytic organ bilobed, with one or both lobes extending anteriorly beyond  
339 margin of forebody; proteolytic gland not observed. Pharynx small, difficult to observe, 28–34  
340 (30±3, 3) long, 33–56 (43±12, 3) wide. Testes tandem, small, lobed and smooth; anterior testis  
341 112–168 (132±27, 4) long, 112–120 (116±6, 2) wide, posterior margin at 32–45 (38±6, 4) % of  
342 hindbody. Posterior testis 136–160 (144±11, 4) long, 104–116 (110±8, 2) wide, with posterior  
343 margin at 59–67 (64±3, 5) % of hindbody. Ovary, near anterior extremity of hindbody, oval, 40–  
344 96 (68±40, 2) long, 56–56 (56±0, 2) wide. Vitellaria follicular, confined to hindbody, densely  
345 distributed in ventro-lateral field extending posteriorly to level of copulatory bursa and genital  
346 bulb, without obscuring the latter. Vitelline reservoir intertesticular; median. Uterus with 4–13  
347 (9±3, 9) eggs, 76–108 (95±7.6, 37) long × 40–72 (56±6.9, 37) wide. Copulatory bursa large,  
348 genital bulb round, oval or reniform, 72–144 (111±27, 7) × 74–160 (117±27, 7).

#### 349 *3.4.4.3 Diagnosis*

350 Adults of *Cotylurus marcogliesei* n. sp. possess a typically strigeid morphology, vitellaria  
351 confined to the hindbody, genital bulb in the copulatory bursa and smooth, bi- or trilobed testes  
352 with lobes pointing posteriorly, all of which are characteristic of *Cotylurus*. The wide opening of  
353 the forebody is more representative of *Ichthyocotylurus* Odening, 1969 (Niewiadomska, 2002b),  
354 but the presence of a genital bulb and testes with posterior facing lobes, in addition to CO1

355 sequence similarity (Fig. 4) indicate the species belongs to *Cotylurus*. The most morphologically  
356 similar species is *C. brevis* Dubois and Rausch, 1950, from which molecular data are  
357 unavailable. The hindbody of *C. marcogliesei* n. sp. is 2.1–2.8 times as long as the forebody,  
358 while in *C. brevis* it is 1.3–1.9 times as long (Dubois, 1970b) (Supplementary Table 4). Mature  
359 adults of *C. marcogliesei* n. sp. are 816–1152 (mean 990) in total length, and half of the  
360 specimens were shorter than the minimum length of *C. brevis* (1000–1800) (Dubois, 1970b). The  
361 pharynx is shorter in *C. marcogliesei* n. sp. (28-34) than in *C. brevis* (50-59), although this organ  
362 is difficult to visualize in both species (Dubois, 1970b) and may not be a reliable character for  
363 identification or discrimination. To our knowledge, no members of the genus *Cotylurus* have  
364 been recorded from *Lophodytes* (Anatidae, Merginae), which further distinguishes it from *C.*  
365 *brevis*, originally described in Europe and found mainly in *Aythya* and *Anas* spp. (Anatidae,  
366 Anatinae).

367 Type host: *Lophodytes cucullatus* (definitive host)

368 Site of infection: Small intestine (definitive host)

369 Type locality: Montreal, Quebec, Canada (50.183 N, –98.383 W) (definitive host)

370 Type material: Holotype (adult worm) Voucher accessions forthcoming;

371 Representative DNA sequences: CO1: XXXXXXXX.

372 Etymology: The species is named after David J. Marcogliese, for his contributions to  
373 parasitology.

374 Partial CO1 sequence was obtained from one of two specimens of *C. flabelliformis* from *Aythya*  
375 *vallisneria* collected in Manitoba. The paragenophore was 782 long, with forebody 351 × 367,

376 strongly arched dorsally, hindbody  $638 \times 399$ , oral sucker  $64 \times 96$ , pharynx  $44 \times 44$ , ventral  
377 sucker  $88 \times 112$ , eggs ( $n=30$ )  $93-100 \times 50-60$ , and its dimensions, morphology, host and  
378 geographic provenance agree with the collective accounts of Dubois (1970b), Campbell (1971)  
379 and Lapage (1961). Sequences of CO1 were obtained from three specimens of *Cotylurus*  
380 *strigeoides* Dubois, 1958 from *Aythya collaris*. The three hologenophores were 1818 long, with  
381 forebody 64 long, hindbody  $1313-1475 \times 747-768$ , oral sucker  $160 \times 112$ , pharynx  $88 \times 76$ ,  
382 ventral sucker  $192 \times 136$ , ovary  $152-231 \times 128-207$ , anterior testis  $223-283 \times 239-423$ , posterior  
383 testis  $271-319 \times 271-343$ , eggs ( $39 \leq n \leq 79$ )  $88-98 \times 56-64$ . The CO1 sequences from *C.*  
384 *strigeoides* were 1.1-1.5% divergent from a CO1 sequence (JX977781) of a worm from *Aythya*  
385 *affinis* collected in Sonora, Mexico (Hernández-Mena et al., 2014). Because of the low level of  
386 divergence between *C. strigeoides* and JX977781, we believe all these data originate from *C.*  
387 *strigeoides*, but JX977781 is identified as *C. gallinulinae*. The material we examined was  
388 distinguished from *C. gallinulinae* by a large pharynx (5% of total length, and over half the size  
389 of the oral sucker, versus  $\leq 2\%$  of total length, and less than half the size of the oral sucker in *C.*  
390 *gallinulinae*, Dubois, 1970b), and the position of the ovary immediately posterior to the division  
391 of the fore- and hindbody (Dubois, 1958), whereas in *C. gallinulinae* it lies further posterior (Fig.  
392 211 in Dubois (1970b)). Records in Manitoba and Sonora are plausible for *C. strigeoides*, which  
393 is known from California and Alaska, whereas *C. gallinulinae* is neotropical (Dubois, 1970b;  
394 McDonald, 1981). Both JX977781 and the specimens we identified as *C. strigeoides* were from  
395 anatid hosts, which is typical for *C. strigeoides*, whereas *C. gallinulinae* is known from members  
396 of the Raillidae (Dubois, 1970b; McDonald, 1981). Within *Cotylurus* as whole, CO1 varies 0-  
397 0.3% (mean 0.2%) within species and 3.4-11.2% (mean 8.3%) between species (considering  
398 JX977781 as *C. strigeoides*). Sequences of CO1 from *C. marcogliesei* n. sp. differed by 7.9-

399 9.3% from other species of *Cotylurus*. The rDNA operon of *C. marcogliesei* n. sp. differs from  
400 other species of *Cotylurus* by 0.7-3% (JX977841, KY513180-2, MF398340).

401 *3.4.5 Alaria americana* Hall and Wigdor, 1918 (Fig. 8)

402 [Measurements from 8 specimens (2 hologenophores, 6 paragenophores), ex *Vulpes vulpes*,  
403 Nova Scotia, Canada]

404 Total length 2121–2868; forebody and hindbody separated by shallow constriction. Forebody  
405 with foliaceous lateral margins folded over ventral surface, 1375–1858 long, 465–869 wide.

406 Hindbody oval, 606–1010 long, 252–559 wide. Forebody 1.6–2.3 times longer than hindbody.

407 Lappets 136–240 long, with stippled glandular tissue along outer margin and protruding from  
408 anterior extremity lateral to oral sucker, 64–120 × 50–119. Ventral sucker 88–104 × 88–120.

409 Tribocytic organ originating posterior to ventral sucker, 667–788 long, 160–250 wide. Pharynx  
410 muscular, pyriform, 120–150 long, 45–96 wide, wider posteriorly, larger than oral sucker.

411 Pharynx length 1.2–2.0 times oral sucker length. Testes in anterior two thirds of hindbody.

412 Anterior testis smooth, unevenly lobed, lateral, 110–319 × 120–327, situated opposite Mehlis'  
413 gland. Posterior testis sub-symmetrical, extending laterally across hindbody width, with two

414 lateral, round lobes, 80–223 × 152–270. Ovary lateral near anterior extremity of hindbody, round  
415 to oval, 67–160 × 65–280 wide. Vitellaria mainly in forebody, dense in tribocytic organ,

416 extending anterior to or just past ventral sucker, extending posterior to or slightly beyond

417 forebody-hindbody constriction. Ejaculatory pouch fusiform, 250–444 × 101–135, with muscular  
418 walls 31–55 thick, extending from posterior testis, or just posterior, to dorsally opening genital

419 atrium. Seminal vesicle with sinuous with transverse sections lying dorsal to ejaculatory pouch,

420 posterior to posterior testis. Vitelline reservoir intertesticular; median. Eggs 0–11, 102–136 long

421 × 36–80 wide. (means, standard deviations, n structures measured in Supplementary Table 5)

422 3.4.5.1 Remarks

423 Dubois (1970b) considered *A. americana* a junior synonym of *A. marciana*e. The morphological,  
424 molecular and life-history data herein support Johnson (1970) and Pearson and Johnson (1988),  
425 who maintained *A. americana* as valid (Supplementary Table 5). Adults of *A. americana* are  
426 larger (>2000) than those of *A. marciana*e (<2000) and have a thicker-walled ejaculatory pouch  
427 (>20 compared with <20 in *A. marciana*e). The CO1 from adults from *Vulpes vulpes* in Nova  
428 Scotia matched (i.e., 98.4-99.8% similarity) sequences from two mesocercariae from a  
429 *Lithobates clamitans* in Quebec. Both *V. vulpes* and *L. clamitans* are known hosts of *A.*  
430 *americana* in North America (Dubois, 1970b). Adults of this species occur in canid definitive  
431 hosts, while *A. marciana*e mainly matures in felid and mustelid hosts (Pearson and Johnson,  
432 1988). The adult *A. marciana*e sequenced in Uhrig et al. (2015) was collected from *Taxidea*  
433 *taxus* (Mustelidae).

434 In *A. americana* and other *Alaria* spp., intraspecific CO1 distances range from 0 to 2.9% and  
435 interspecific distances from 8.4 to 13.1% (total 53 CO1 sequences from *A. americana*, *A.*  
436 *mustelae*, and *A. marciana*e; *A. marciana*e includes *Alaria* sp. 2 of Locke et al. (2011) as noted  
437 by Uhrig et al. (2015), who recorded the sequence match but mistakenly referred to *Alaria* sp. 1  
438 of Locke et al. (2011)). We also include here new CO1 records from *A. mustelae* from *Martes*  
439 *pennanti* from Wisconsin.

440 The rDNA operon of *A. americana* assembled from genomic data differs by 2.2-13.5% from 13  
441 sequences from *A. mustelae*, *A. marciana*e, *A. alata* and three unidentified species of *Alaria*  
442 (comparisons of various regions of the rDNA array, limited to sequences overlapping > 500 bp,  
443 AF184263, AY222091, JF769477-8, JF769480, JF769482, JF769484, JF820605, JF820607,  
444 JF820609, KT254014, KT254021, KT254023). Notably, *A. americana* differs from *A.*

445 *marciana* by 6.1% in partial 28S rDNA (914/973 identities with KT254021-2, Uhrig et al.,  
446 2015)) and by 8.4-8.9% in partial CO1 (KT254037-9, Uhrig et al. 2015).

447 *3.4.6 Hysteromorpha triloba* (Rudolphi, 1819) (Fig. 8, Supplementary Fig. 3)

448 [Metacercaria; measurements from 7 paragenophores, ex lateral and cheek muscle of *Squalius*  
449 *cephalus* (mean weight 67 g) from Bidente River, Forli-Cesena province, Emilia Romagna  
450 region, Italy; 10/10 fish infected with hundreds of metacercariae.]

451 Total length 776–889 (830±42, 7); body oval or pyriform, with poor demarcation between  
452 forebody and hindbody. Forebody round 536–664 (606±48, 7) long, 576–687 (630±33, 7) wide,  
453 with pseudosuckers forming cup-shaped depressions 48–80 (64±12, 7) deep, 44–96 (69±14, 12)  
454 wide. Hindbody bluntly triangular, roughly 120–303 (225±62, 7) long, 256–545 (404±96, 7)  
455 wide at widest point, where it joins forebody. Oral sucker terminal, 72–125 (82±19, 7) long, 52–  
456 84 (70±12, 7) wide. Pharynx 50–76 (61±10, 7) long, 30–44 (36±4, 7) wide. Ventral sucker 60–  
457 82 (70±8, 7) long, 88–107 (99±6, 7) wide, sometimes anterior to, sometimes covered by  
458 tribocytic organ. Tribocytic organ trilobed, 160–229 (193±27, 6) long, 163–320 (207±54, 7)  
459 wide. Oesophagus 20–47 (34±19, 2) long, caeca almost reaching end of hindbody, flanking or  
460 passing ventrally over genital primordia in hindbody.

461 *Hysteromorpha corti* comb. nov. (Hughes, 1929) (Fig. 10)

462 [Adult; measurements from 12 paragenophores, ex *Phalacrocorax auritus*, Montreal, Quebec,  
463 Canada]

464 Total length 1052 – 1633 (1314±172, 12); forebody and hindbody separated by constriction.  
465 Forebody spatulate, 490 - 762 (664±86, 12) long, 404 - 707 (509±82, 12) wide. Hindbody oval,  
466 490 - 943 (658±125, 12) long, 381 - 636 (480±68, 12) wide. Pseudosuckers forming recessed

467 depressions in forebody, 47 - 129 (78±26, 9) deep, 70 - 200 (105±38, 9) across. Oral sucker 50 -  
468 107 (75±16, 12) × 71 - 107 (86±12, 12). Ventral sucker 36 - 107 (75±18, 11) × 43 - 143 (93±30,  
469 11). Tribocytic organ 142 - 321 (241±58, 12) long, 190 - 293 (237±33, 11) wide. Pharynx  
470 muscular, pyriform, 52–68 (59±6, 5) long, 40–70 (52±11, 5) wide. Ovary 71 - 100 (85±14, 5) ×  
471 64 - 114 (81±19, 5), anterior to anterior testis. Anterior testis smooth, unevenly lobed, lateral,  
472 107 - 214 (169±31, 10) × 107 - 250 (171±48, 7). Posterior testis extending laterally across  
473 hindbody width, with two lateral, round lobes, 143 - 229 (171±35, 9) × 357 - 500 (423±51, 8).  
474 Vitelline reservoir intertesticular; sub-median. Vitellaria from anterior to ventral sucker to  
475 posterior extremity, forming a narrow ventral band in hindbody at level of testes. Genital atrium  
476 subterminal, dorsal. Eggs 0–9, 87–109 (96±6, 12) long × 44–66 (54±6, 12) wide.

477 [Metacercaria; measurements from 7 syngenophores, ex *Catostomus commersoni* (n=1),  
478 *Notemigonus crysoleucas* (n=5), Montreal and Great Lakes region, Canada]

479 Total length 712–880 (796±55, 7); body oval or shield-shaped, with poor demarcation between  
480 forebody and hindbody. Forebody round 640–696 (670±25, 5) long, 384–472 (428±34, 7) wide.  
481 Hindbody bluntly triangular, roughly 80–160 (126±32, 5) long, 152–200 (176±34, 2) wide at  
482 widest point, where it joins forebody. Oral sucker terminal, 60–68 (62±4, 5) long, 56–68 (63±4,  
483 5) wide. Pharynx 32–35 (33±2, 3) in diameter. Ventral sucker 56–68 (60±6, 5) long, 60–76  
484 (73±6, 6) wide, sometimes anterior to, sometimes partly covered by tribocytic organ. Tribocytic  
485 organ trilobed, 136–176 (163±18, 4) long, 116–160 (137±19, 5) wide.

#### 486 3.4.6.1 Diagnosis and Remarks

487 Sequences of CO1 from metacercariae of *H. triloba* from Italy differed by 6.9-9.7 (mean 8.7)%  
488 from material collected in North and Central America (Fig. 4). Among the Italian isolates, CO1

489 varied by 0.3-0.8 (mean 0.5)%, and among American samples, by 0-5.6 (mean 1.7)%. The rDNA  
490 operon of Italian *H. triloba* differed from American isolates by 0-0.2% from 18S and 28S  
491 subunit sequences 1281-1694 bp in length (HM114365, MF398354-7) and by 0.1-0.3% to ITS1-  
492 5.8S-ITS2 sequences 1017-1261 in length (HM064925-7, JF769486, MG649479-93). These 20  
493 aligned ITS sequences from *Hysteromorpha* had three variable sites, with one transitional  
494 mutation in ITS1 private to the Italian sequence. Rudolphi (1819) described *Hysteromorpha*  
495 *triloba* (as *Distoma trilobum*) in Europe from four adults from *Phalacrocorax carbo* collected by  
496 Bremser, who was based in Vienna (Sattmann et al., 2014). The type host has a wide, but mainly  
497 Eurasian distribution (Hatch et al., 2000). A description of metacercaria of *H. triloba* from  
498 cyprinids in Europe by Ciurea (1930) largely agrees with our observations of metacercariae from  
499 *S. cephalus* (Cyprinidae), and the ventral and oral suckers, pharynx and oesophagus are generally  
500 smaller in European than in American isolates (Supplementary Table 6). We consider these  
501 European and American isolates of *Hysteromorpha* to be separate species, even if meristic or  
502 morphological differences were not discerned between American and European adults of  
503 *Hysteromorpha* based on available data and descriptions (Supplementary Table 6), and rDNA  
504 divergence levels are small. Because the species was described in Europe, from a host with a  
505 Palearctic distribution, and similar metacercariae are known from cyprinids in Europe (see also  
506 records in Bykhovskaya-Pavlovskaya, 1962), the name *H. triloba* is reserved for the Palearctic  
507 lineage. In the Nearctic, Hughes (1929) provided the first description of *Hysteromorpha*, from  
508 metacercariae in the muscle of *Ameiurus nebulosus* and *Ameiurus melas* in the Illinois River.  
509 Hughes (1929) named these metacercariae *Diplostomulum corti*. Huggins (1954a, 1954b)  
510 synonymized *D. corti* with *Hysteromorpha triloba* (Rudolphi, 1819) Lutz 1931. The North  
511 American species of *Hysteromorpha* will therefore bear the name created by Hughes (1929).

512 3.4.7 *Tylodelphys immer* Dubois, 1961 (Fig. 11).

513 [Measurements from 5 adult paragenophores, ex *Gavia immer*.]

514 Total length 1515–1636; body linguiform, poor demarcation between forebody and hindbody.

515 Forebody 970–1111 long, 455–556 wide, oval in shape with pointed anterior flanked by

516 conspicuous pseudosuckers 160–232; forebody widest usually in anterior third (4/5 specimens).

517 Ventral surface tegument with plicate folds on anterior half to two thirds of forebody. Cylindrical

518 hindbody tapering to terminate in rounded extremity, 525–566 long, 284–404 wide. Hindbody

519 length / forebody length 0.47–0.56; hindbody width / forebody width 0.51–0.85. Oral sucker

520 terminal, 80–119 long, 100–127 wide. Pharynx well developed, 68–84 long, 66–80 wide. Ventral

521 sucker 90–109 long, 100–131 wide, situated slightly more than halfway along length of

522 forebody, the anterior edge occurring 51–54% from anterior end of forebody. Tribocytic organ

523 oval to round, 240–288 long, 152–240 wide. Ovary round or bilobed, small, sub-median, near or

524 overlapped by postero-lateral edge of tribocytic organ, 40–80 long, 56–80 wide. Testicular zone

525 extending posteriorly from forebody-hindbody division, occupying first 29–39% of hindbody.

526 Testes tandem, symmetric, bilobed. Anterior testis 80–96 long, 272–344 wide, wider than

527 posterior testis. Posterior testis 88–112 long, 272–320 wide. Vitelline field densest in vicinity of

528 tribocytic organ, extending two thirds of length of forebody, ending 31–34% of distance from

529 anterior edge of ventral sucker to anterior extremity, in hindbody narrowing to a ventral strip

530 between lobes of posterior testis, terminating in a lateral band at level of seminal vesicle.

531 Vitelline reservoir intertesticular, sub-median. Copulatory bursa with subterminal, wide, thick-

532 walled ventral opening 168–184 long, 160–184 wide, housing well-developed genital cone 112–

533 152 wide. Uterus with 1–8 eggs, 82–100 long × 44–68 wide.

534 3.4.8 *Remarks*

535 Most of these observations and dimensions agree with the account of Dubois (1970b)  
536 (supplementary Table 7), although he did not comment on the tegument; a pseudosucker on one  
537 specimen was shorter (160 *versus* 180 minimum length in Dubois, 1970b); the pharynx was  
538 wider in three worms (74-80 *versus* maximum of 70 in Dubois, 1970b); the ventral sucker was  
539 longer in 4 worms (104–109 *versus* 100 in Dubois (1970b) and wider in one (131 *versus* 122 in  
540 Dubois, 1970b); the ovary was smaller (40–80×56–80 *versus* 95–115×80–145 in Dubois, 1970b)  
541 and more median in 3 worms; the anterior testis was shorter in 3 worms (80-88 *versus* 90 in  
542 Dubois, 1970b), the posterior in one (88 *versus* 90 in Dubois, 1970b); and the genital cone was  
543 wider in 2 worms (152 *versus* 135 in Dubois, 1970b). These variations seem within that to be  
544 expected within species, and thus not taxonomically significant. They could reflect differences in  
545 maturity, as the worms included in our analysis had 0-8 eggs, while Dubois (1970b) examined  
546 material with 4-17 eggs, or again might be artefacts of differences in specimen preparation.

547 The specimens used for morphological and genomic analysis in the present study were from the  
548 same individual host as the *T. immer* studied by Locke et al. (2015), and the mitochondrial  
549 genome and rDNA operon were 98.1-99.9 % similar to CO1 (Fig. 4) and identical to ITS  
550 sequences (KT186804-6) of Locke et al. (2015).

#### 551 **4. Discussion**

552 We confirmed and expanded on recent analyses showing a paraphyletic pattern of mt  
553 genome evolution in the Diplostomida (Brabec et al., 2015; Briscoe et al., 2016; Chen et al.,  
554 2016). The mt genomic phylogeny conflicts with the rDNA phylogeny upon which the  
555 Diplostomida was erected (Figs. 1, 2). There were about one quarter as many variable sites in the  
556 rDNA alignment as in our alignment of mt nucleotides (1444 variable sites in Olson et al., 2003).  
557 Thus, the well-supported mt topology in Fig. 2, containing members of two of three

558 superfamilies in the Diplostomida, might have cast doubt on the validity of the order. However, a  
559 much larger genomic dataset, which we had designated as an arbiter between mitonuclear  
560 alternatives, yielded unequivocal support for the order (Fig. 3).

561         Discordance between nuclear and mt phylogenies is not uncommon, and although it is  
562 more often recorded at shallower nodes than in the present study (e.g., Perea et al., 2016; Platt et  
563 al., 2018), differences also occur among deeply divergent lineages (e.g., Sun et al., 2015, and  
564 compare Inoue et al., 2003 and Faircloth et al., 2013). In the present case, the discrepancy occurs  
565 along short internal branches at the base of longer terminal branches (Figs. 2, 3). This is  
566 consistent with ancient, rapid radiation, which is inherently difficult to resolve, particularly in  
567 conjunction with incomplete lineage sorting (Whitfield and Lockhart, 2007). Along these short  
568 internal branches, mitochondrial genomes of digeneans may have a lower phylogenetic  
569 signal/noise ratio than nuclear genes, exacerbating effects of incomplete taxon sampling  
570 (Graybeal and Cannatella, 1998; Hedtke et al., 2006; Philippe et al., 2011). Genomic data (both  
571 mt and nuclear) from other diplostomidans and early, divergent lineages from the Plagiorchiida  
572 are needed to clarify this (Brachylaimoidea Joyeux and Foley, 1930, Liolopidae Odhner, 1912,  
573 Aporocotyliidae Odhner, 1912, Spirorchiidae Stunkard, 1921, Bivesiculoidea Yamaguti, 1934).

574         Within the Diplostomoidea, however, the mt and UCE phylogenies are congruent, which  
575 suggests they reflect evolutionary relationships among the species studied. Figures 2 and 3 also  
576 share elements that recur in prior work. In most molecular phylogenies, the superfamily is  
577 monophyletic and cyathocotyliids are basal (Blasco-Costa and Locke, 2017; Dzikowski et al.  
578 2004; Hernández-Mena et al., 2017), as herein. Both the branching order and composition of the  
579 major diplostomoid clades in Figs. 2 and 3 herein are consistent with an analysis of concatenated  
580 CO1 and rDNA spacer sequences by Blasco-Costa and Locke (2017). The association of

581 *Hysteromorpha*, *Alaria*, *Tylodelphys* and *Diplostomum* is consistent with trees in Fraija-  
582 Fernández et al. (2015), López-Jiménez et al. (2017), and Olson et al. (2003). Discrepancies  
583 (e.g., *Hysteromorpha* in Hernández-Mena et al., 2017) are typically associated with poor nodal  
584 support. These genera are also consistently associated with *Austrodiplostomum* and  
585 *Neodiplostomum* (Blasco-Costa and Locke, 2017; Hernández-Mena et al., 2017; Locke et al.,  
586 2015; the latter sometimes misidentified as *Fibricola*, see Blasco-Costa and Locke, 2017), and  
587 the name Diplostomidae should be reserved for members of this group.

588         Like other studies, our analysis indicates the Diplostomidae *s.l.* is paraphyletic.  
589 *Posthodiplostomum*, though nominally part of the family, is separate from and basal to a clade  
590 composed of other diplostomids and the Strigeidae. *Posthodiplostomum* belongs to the  
591 Crassiphialinae Sudarikov, 1960 and is consistently recovered with other members of this  
592 subfamily (e.g., *Uvulifer*, *Bolbophorus*, *Ornithodiplostomum*, *Mesophorodiplostomum* and  
593 *Posthodiplostomum* in Athokpam and Tandon, 2014; Blasco-Costa and Locke, 2017; Hernández-  
594 Mena et al., 2017; López-Jiménez et al., 2017; Sereno-Uribe et al., 2018; Locke et al., 2010, see  
595 fig. S4). One recent analysis suggests some of these genera are not distinct (López-Hernández et  
596 al., 2018). As noted by Blasco-Costa and Locke (2017) and Hernández-Mena et al. (2017), it  
597 appears that the Crassiphialinae will rise to the family level, although it would be prudent to  
598 obtain data from the type genus, *Crassiphiala* Van Haitsma, 1925, before enacting this.

599         Both the present and the weight of prior phylogenetic analysis (see above) suggest that  
600 some family-level clades in the Diplostomoidea are distinguishable by long-recognized  
601 metacercarial morphotypes. For example, crassiphialinids and other diplostomids are clearly  
602 evolutionarily distinct, and readily separated by their metacercariae (neascus and  
603 diplostomulum). In adult forms, members of these two clades are sometimes discriminated by

604 the distribution of the vitellaria, but this character fails in many cases (Niewiadomska, 2002c).

605 The view that the metacercaria offers an impoverished subset of the phylogenetically informative

606 characters found in the adult (Gibson, 1987) seems not to apply in the Diplostomoidea. For

607 example, the infection sites and encystment habits of metacercariae may be phylogenetically

608 conserved. Diplostomid genera with metacercariae that reside unencysted in the eyes of second

609 intermediate hosts consistently group together in molecular phylogenies (Blasco-Costa and

610 Locke, 2017; Hernández-Mena et al., 2017) and in *Diplostomum*, habitats within the eye are

611 conserved (Blasco-Costa et al., 2014) and may influence diversification (Locke et al., 2015).

612 Some morphological characters are also more easily visualized in metacercariae. For example,

613 the character that mapped best onto phylogenetic analysis herein, the structure of the reserve

614 bladder, is seldom described in the adult, likely because it is obscured by reproductive structures

615 in mature worms (for an exception, see Overstreet et al., 2002). The value of this character fits

616 Niewiadomska's (2002a) concept of four main morphotypes. Shoop (1989) distinguished

617 additional types of metacercariae, but molecular phylogenies have not supported their

618 distinctness (e.g., see *Neodiplostomum/Fibricola*, and *Bolbophorus*, which possess neo- and

619 prodiplostomula in Shoop's system, in Blasco-Costa and Locke, 2017; Hernández-Mena et al.,

620 2017). Further assessing the evolution of metacercarial characters and morphotypes will require

621 additional molecular and morphological analysis. In the Strigeidae, all metacercariae are of a

622 single type (tetracotyle), but the family is frequently non-monophyletic in molecular studies

623 (Blasco-Costa and Locke, 2017; Hernández-Mena et al., 2017). It would be fruitful to

624 characterize the reserve bladder in metacercariae belonging to the Proterodiplostomidae, which

625 Hernández-Mena et al. (2017) found to be an early diverging, but not basal member of the

626 diplostomoid clade. The simpler reserve bladder in the Cyathocotylidae, and the reticulate forms

627 with transverse commisures in the crown clade of Strigeidae and Diplostomidae, predict  
628 intermediate complexity in proterodiplostomids.

629         The initial aim of this study was a phylogenomic evaluation of higher relationships  
630 among a small number of worms. To this end, we selected seven specimens identified to genus  
631 that were promising for shotgun sequencing. After closer examination of vouchers, we recorded  
632 a new species of *Cotylurus*, resurrected a species of *Hysteromorpha*, and found support for a  
633 species of *Alaria* of contested validity, and these findings were supported with molecular data.  
634 Identifications were less than straightforward in 3/7 cases, a proportion similar to the 20/44  
635 studies in which diplostomoid diversity differed from expectations (reviewed by Blasco-Costa  
636 and Locke, 2017). One taxonomic result involved reconsideration of *H. triloba*, which has long  
637 been thought to be cosmopolitan (Hughhins, 1954b; Locke et al., 2011; Lutz, 1931; Sereno-  
638 Uribe et al., 2018). The genetic divergence seen in *Hysteromorpha* could be construed as  
639 intraspecific variation in widely separated populations (particularly the low level of rDNA  
640 variation), but we believe recently formed species to be a more plausible explanation. In addition  
641 to the molecular evidence, the non-overlapping ranges of the definitive hosts of Nearctic and  
642 Palearctic *Hysteromorpha* (i.e., *Phalacrocorax* spp.) suggest long isolation, and the distinction  
643 between *H. triloba* and *H. corti* are supported by morphological differences in the metacercaria.  
644 Moreover, the finding that *Hysteromorpha* is represented by a distinct species in North America,  
645 *H. corti*, is consistent with a general trend. With sequences now available from thousands of  
646 specimens and many valid and putative species of diplostomoids and clinostomids,  
647 intercontinental distributions supported by molecular data are exceedingly rare, and limited to  
648 distributions along the margins of a second continent (e.g., *Austrodiplostomum compactum* (=A.  
649 *ostrowskiae*), Locke et al. 2015). More commonly, a single species thought to cosmopolitan is

650 revealed by DNA to be comprised of multiple geographically isolated species (e.g., *Diplostomum*  
651 *spathaceum*, *D. baeri*, *Clinostomum complanatum*, Caffara et al., 2011; Galazzo et al., 2002;  
652 Locke et al., 2015). The presence of the North American species, *P. centrarchi*, in Europe  
653 (Kvach et al., 2017; Stoyanov et al., 2017) and the Caribbean (Bunkley-Williams and Williams,  
654 1994; present study) is instructive, as it is associated with recent introductions of non-native  
655 intermediate hosts. The overall pattern suggests intercontinental distributions based on historical  
656 records should be regarded skeptically in diplostomoids, clinostomids, and, we would suggest,  
657 other digeneans with life cycles tied to fresh water. For example, we predict that DNA will  
658 reveal that Palearctic *Apharyngostrigea cornu* is distinct from North American isolates  
659 sequenced by Locke et al. (2011). Because *A. cornu* was described in Europe (Zeder, 1800), the  
660 North American lineage will need to be renamed. Similarly, the Holarctic distribution of  
661 *Cotylurus brevis* (Dubois, 1970b; McDonald, 1981) seems doubtful. South American isolates of  
662 *H. triloba* (Lunaschi et al., 2007; Lutz, 1931) are also likely to represent another species, distinct  
663 from the North American and European lineages.

#### 664 **Acknowledgements**

665 We are indebted to Brandon Ballengée (McGill University), Kimberly Bates (Winona State  
666 University), Matías J. Cafaro (University of Puerto Rico at Mayagüez, UPRM), Gary Conboy  
667 (University of Prince Edward Island), Martin Kalbe (Max Planck Institute for Evolutionary  
668 Biology), David Kerstetter (Nova Southeastern University), Audrey J. Majeske (UPRM), J.  
669 Daniel McLaughlin (Concordia University), and Le Nichoir Wildlife Rehabilitation Centre for  
670 providing hosts, worms, or laboratory access. Lutz Froenicke and staff at the UC Davis Genome  
671 Center are gratefully acknowledged. Isabel Blasco-Costa (Natural History Museum of Geneva)  
672 provided constructive suggestions that improved an earlier version of the manuscript. Early

673 phases of this study were supported by the Canadian Federal Government's Genomics Research  
674 Development Initiative, an NSERC Discovery Grant (A6979), and by Paul D. N. Hebert at the  
675 Center for Biodiversity Genomics, University of Guelph, Canada through funding from NSERC,  
676 Genome Canada, the Ontario Genomics Institute and the International Barcode of Life initiative.  
677 Major funding support was provided by the Puerto Rico Science, Technology and Research Trust  
678 to SL and computational support was provided to by an NSF-XSEDE grant (TG-BIO170048) SL  
679 and AVD.

## 680 **Figure legends**

681 **Fig. 1.** Schematic of phylogenetic conflict in the Digenea emerging from prior studies. Analysis  
682 of nuclear rDNA (nDNA) indicates *Diplostomum*, *Clinostomum*, and *Schistosoma* belong to the  
683 Diplostomida (Olson et al., 2003), while mitochondrial genomes (mtDNA) indicate  
684 *Diplostomum* and *Clinostomum* belong to the Plagiorchiida (Brabec et al., 2015; Briscoe et al.,  
685 2016; Chen et al., 2016). A polytomy occurs in the mitochondrial phylogeny because  
686 *Diplostomum* and *Clinostomum* have not been included together in prior analysis.

687 **Fig. 2.** Phylogenetic analysis of seven representatives of the Diplostomoidea and 29 other  
688 members of the Platyhelminthes, estimated using maximum likelihood based on 5647 variable  
689 sites in 13 protein-coding genes in the mitochondrion. Nodes are labelled with support from  
690 1000 bootstrap replicates, with support from analysis of translated amino acids (supplementary  
691 Fig. 2) after the slash. Unlabelled nodes indicate support of 100/100. An asterisk and grey branch  
692 indicate topological inconsistency with analysis of amino acids. GenBank accessions of  
693 sequences from other studies are AF215860.1, AF216697.1, AF217449.1, AF219379.2,  
694 DQ157222.2, DQ157223.1, DQ859919.1, DQ985706.1, EU921260.2, FJ381664.2, HE601612.1,  
695 KC330755.1, KF214770.1, KF318786.1, KF318787.1, KF475773.1, KF543342.1, KM280646.1,

696 KM923964.1, KP844722.1, KR269763.1, KR269764.1, KR703278.1, KT239342.1,  
697 KU060148.1, KU641017.1, KX169163.1, KX765277.1, MF136777.1.

698 **Fig. 3.** Maximum likelihood analysis of 517 conserved genetic elements from seven members of  
699 the Diplostomoidea, and other Platyhelminthes. The gray or black shaded boxes indicate families  
700 recognized by Dubois (Dubois, 1938, 1970b) and Niewiadomska (Niewiadomska, 2002a).  
701 Colors in matrix at right encode morphological and life history characters separated by  
702 developmental stage (supplementary Table 1). Metacercarial morphotypes indicated at far right  
703 are: P=prohemistomulum, D=diplostomulum, N=neascus, T=tetracotyle. The alignment is  
704 234,783 bp in length, with 149,881 (64%) invariant and 84,902 (36%) variable sites. The  
705 analysis was based on 90% matrix occupancy. Nodes had 100% support in 1000 bootstrap  
706 replicates, except where indicated. Accessions of non-diplostomoid genomes obtained from  
707 Wormbase (Howe et al., 2016) are PRJEB1206, PRJDA72781, PRJEB6687, PRJEB1207.

708 **Fig. 4.** Neighbour-joining tree of uncorrected p-distance among 195 partial sequences of  
709 cytochrome *c* oxidase I (COI). Shaded clades had >99% support in 500 bootstrap replicates in  
710 ML analysis (not shown) and are annotated with identifications, host and geographic records  
711 mentioned in the results. Sequences from the present study were obtained from species labelled  
712 in bold. This includes Sanger-sequenced amplicons of the barcode region of COI (n=35,  
713 XXXXXX-X) and mitochondrial genomes of specimens used in Figures 2 and 3. Sequences  
714 (n=160) from other studies are FJ477182, FJ477203, FJ477217, HM064651-9, HM064712,  
715 HM064714-7, HM064799-843, JF769422-76, JF904528-36, JX977781-4, KR271481-93,  
716 KT254037-9, KX931421-3, KY513231-6, MF124272-3, MF398316, MG649464-78.

- 717 **Fig. 5.** Adult of *Posthodiplostomum centrarchi* Hoffman, 1958, from *Ardea herodias*, Ile aux  
718 Herons, St. Lawrence River, Quebec, Canada. Scale = 200  $\mu$ m. Hologenophore for partial  
719 sequence of cytochrome *c* oxidase I, Genbank accession XZXXXXXX.
- 720 **Fig. 6.** Adult of *Cardiocephaloides medioconiger* Hall & Wigdor, 1918, from *Thalassius*  
721 *maximus*, Florida, United States. Scale = 2000  $\mu$ m. Hologenophore for partial sequence of  
722 cytochrome *c* oxidase I, Genbank accession XZXXXXXX.
- 723 **Fig. 7.** Adults of *Cotylurus marcogliesei* n. sp. from *Lophodytes cucullatus* in Montreal, Quebec,  
724 Canada. Scale = 200  $\mu$ m. Hologenophores for Genbank accession XZXXXXXX.
- 725 **Fig. 8.** Adult of *Alaria americana* Hall & Wigdor, 1918, from *Vulpes vulpes*, Nova Scotia,  
726 Canada. Scale = 500  $\mu$ m. Paragenophore for partial sequence of cytochrome *c* oxidase I,  
727 Genbank accession XZXXXXXX.
- 728 **Fig. 9.** Metacercariae of *Hysteromorpha triloba* (Rudolphi, 1819) from *Squalius cephalus*, Italy.  
729 Scale = 200  $\mu$ m. Paragenophores for partial sequence of cytochrome *c* oxidase I, Genbank  
730 accession XZXXXXXX.
- 731 **Fig. 10.** Adult of *Hysteromorpha corti* (Hughes, 1929) from *Phalacrocorax auritus*, Montreal,  
732 Quebec, Canada. Italy. Scale = 200  $\mu$ m. Paragenophore for partial sequence of cytochrome *c*  
733 oxidase I, Genbank accession XZXXXXXX.
- 734 **Fig. 11 (a).** Adult of *Tylodelphys immer* Dubois, 1961, from *Gavia immer* in Montreal, Quebec,  
735 Canada. Scale = 200  $\mu$ m. **(b).** Ventral tegument of forebody. VS=ventral sucker, arrow points to  
736 anterior of worm. Scale = 50  $\mu$ m. Paragenophore for partial sequence of cytochrome *c* oxidase I,  
737 Genbank accessions KR271483, KR271487, KR271489.

738 **Supplementary Fig. 1.** Characters mapped onto the topology of the phylogenomic analysis of  
739 the Diplostomoidea.

740 **Supplementary Fig. 2.** Phylogenetic analysis of seven representatives of the Diplostomoidea  
741 and 29 other members of the Platyhelminthes, estimated using maximum likelihood based on  
742 translated amino acids in 13 protein-coding genes in the mitochondrion

743 **Supplementary Fig. 3.** Metacercariae of *Hysteromorpha triloba* in muscle of *Squalius cephalus*.  
744 A-B: live metacercariae (scale = 100  $\mu\text{m}$ ); Metacercariae in cheek (C), lateral (D) and caudal (E)  
745 muscle.

746 **Supplementary Table 1.** Characteristics of mitochondrial genomes and rDNA operons for seven  
747 members of the Diplostomoidea.

748 **Supplementary Table 2.** Selected morphometrics from adults of *Posthodiplostomum* reported in  
749  $\mu\text{m}$  as range (mean,  $\pm$  standard deviation, n).

750 **Supplementary Table 3.** Selected morphometrics from adults of *Cardiocephaloides*  
751 *medioconiger* reported in  $\mu\text{m}$  as range (mean,  $\pm$  standard deviation, n).

752 **Supplementary Table 4.** Selected morphometrics from adults of *Cotylurus* reported in  $\mu\text{m}$  as  
753 range (mean,  $\pm$  standard deviation, n).

754 **Supplementary Table 5.** Selected morphometrics from adults of *Alaria* reported in  $\mu\text{m}$  as range  
755 (mean,  $\pm$  standard deviation, n).

756

757 **Supplementary Table 6.** Selected morphometrics from metacercariae and adults of  
758 *Hysteromorpha* from the present and other studies, reported in  $\mu\text{m}$  as range (mean,  $\pm$  standard  
759 deviation, n).

760

761 **Supplementary Table 7.** Selected morphometrics from adults of *Tylodelphys immer* reported in  
762  $\mu\text{m}$  as range (mean,  $\pm$  standard deviation, n).

- 11 0=genital bursa absent; 3=genital bursa present
- 12 0=genital cone absent; 3=genital cone present
- 13 0=mesocercaria absent; 3=mesocercaria present
- 14 0=tribocytic organ absent; 1=tribocytic organ lingual; 3=tribocytic organ bilobate
- 15 0=body shape unsegment; 1=slightly segmented; 3=fore/hindbody division
- 16 0=no forebody; 1=flattened forebody; 3=cup-shaped forebody
- 17 0=vitellaria postovarian in hindbody; 1= vitellaria pre- and post ovarian in fore and hindbody; 3=vitellaria pre- and postovarian in hindbody only
- 18 0=pseudosuckers absent; 3=pseudosuckers present

**Metacercaria**

- 19 0=forebody spatulate; 3=forebody cup-shaped
- 20 0=encysted; 3=unencysted
- 21 0=limebodies free; 3=limebodies enclosed
- 22 0=pseudosuckers present; 3=pseudosuckers absent
- 23 0=none; 1=no or weak segmentation; 3=segmented
- 24 0=four excretory canals in two loops; 1=1 median flanked by two lateral canals; 2=one median flanked by 1 in anterior, and 2 in posterior of median anastomosis; 3=net-like web of canals

Supplementary Fig 2. Phylogenetic analysis of seven representatives of the Diplostomoidea and 29 other members of the Platyhelminthes, estimated using maximum likelihood based on an alignment of 3153 translated amino acids (2575 variable sites) in 13 protein-coding genes in the mitochondrion. Nodes are labelled with support from 1000 bootstrap replicates. Branches in grey differ from the topology in the analysis of nucleotide sequences (Figure 2). The analysis was based on JTT model of amino acid evolution.

**Supplementary Figure 3.** Metacercariae of *Hysteromorpha triloba* in muscle of *Squalius cephalus*. **A-B:** live metacercariae (scale = 100  $\mu$ m); Metacercariae in cheek (**C**), lateral (**D**) and caudal (**E**) muscle.

Supplementary Table 1. Characteristics and genomic assembly statistics of mitochondrial genomes and rDNA operons for seven members of the Diplostomoidea
