THE LANCET

Supplementary appendix 1

This appendix formed part of the original submission and has been peer reviewed. We post it as supplied by the authors.

Supplement to: GBD 2017 Risk Factor Collaborators. Global, regional, and national comparative risk assessment of 84 behavioural, environmental and occupational, and metabolic risks or clusters of risks for 195 countries and territories, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017. *Lancet* 2018; **392:** 1923–45.

Methods appendix to Global, regional, and national comparative risk assessment of 84 behavioural, environmental and occupational, and metabolic risks or clusters of risks, 1990-2017: a systematic analysis for the Global Burden of Disease Study 2017

This appendix provides further methodological detail, supplemental figures, and more detailed results for risk factors. The appendix is organised into broad sections following the structure of the main paper.

Preamble

This appendix provides further methodological detail and more detailed results for "Global, regional, and national comparative risk assessment of 84 behavioural, environmental and occupational, and metabolic risks or clusters of risks, 1990-2017: a systematic analysis for the Global Burden of Disease Study 2017." This study complies with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) recommendations. It includes detailed tables and information on data in an effort to maximise transparency in our estimation processes and provide a comprehensive description of analytical steps. We intend this appendix to be a living document, to be updated with each iteration of the Global Burden of Disease Study.

Contents

Authors' Contributions

Managing the estimation process

Ashkan Afshin, Tahiya Alam, Brigette Blacker, Michael Brauer, Aaron Cohen, Elizabeth Cromwell, Lalit Dandona, Rakhi Dandona, Louisa Degenhardt, Samath Dharmaratne, Charbel El Bcheraoui, Kara Estep, Valery Feigin, Nancy Fullman, Emmanuela Gakidou, Caitlin Hawley, Simon Hay, Spencer L James, Nicholas J Kassebaum, Ibrahim Khalil, Hmwe Kyu, Stephen Lim, Alan Lopez, Rafael Lozano, Ashley Marks, Awoke Misganaw, Ali Mokdad, Christopher Murray, Mohsen Naghavi, Elaine Nsoesie, Helen Olsen, Robert Reiner, Gregory Roth, David Smith, Mari Smith, Jeffrey Stanaway, Stein Emil Vollset, Theo Vos, and Harvey Whiteford

Writing the first draft of the manuscript

Jason Anderson, Kate Causey, William Gardner, Sam Larson, Ashley Marks, Molly Nixon, Jeff Stanaway, Anna Torre.

Section 1: GBD overview

Section 1.1: Locations of the Analysis

The locations included in Global Burden of Diseases, Injuries, and Risk Factors Study 2017 (GBD 2017) have been arranged into a set of hierarchical categories composed of seven super-regions and a further nested set of 21 regions containing 195 countries and territories. The locations for which GBD estimated global, regional, and national risk exposure, relative risk, theoretical minimum-risk exposure level (TMREL), and population attributable fractions (PAFs), have not expanded following GBD 2015. Subnational estimation in GBD 2017 includes Brazil, China, India, Indonesia, Japan, Kenya, Mexico, South Africa, Sweden, the United Kingdom, and the United States, and new subnational assessments at the administrative one level for Ethiopia, Iran, Norway, and Russia and by Maori ethnicity for New Zealand. For this publication, we present subnational estimates in figures only for all subnational countries with the exception of the new assessments, which will be reported in separate publications. Select subnational estimates are also included in supplementary results appendix. Combined, there are a total of 390 locations at the first subnational unit level. Included in subnational Level 1 locations are countries that have been subdivided into the first subnational level, such as states or provinces, for the GBD analysis; subnational Level 2 only applies to India, England, and Russia. For this paper, we present data at the national and territory level.

Section 1.2: Time Period of the Analysis

A complete set of risk-specific exposure, relative risk, TMREL, and PAFs were computed for the years 1990-2017. All GBD 2017 results and online data visualisations are available at http://vizhub.healthdata.org/gbd-compare with access to results for all GBD metrics.

Section 1.3: Statement of GATHER Compliance

This study complies with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) recommendations. We have documented the steps involved in our analytical procedures and detailed the data sources used. See Appendix Table 1 for the GATHER checklist.

The GATHER recommendations may be found here: http://gather-statement.org/

Section 1.4: GBD risk factor hierarchy

In this analysis, we focus on three groups of risk factors: behavioural, environmental and occupational, and metabolic. The GBD 2017 risk factors hierarchy and Levels are summarised in Appendix Table 2.

The GBD risk list continues to evolve to reflect the policy relevance, public health, and medical care importance of major risk factors. The risk factors list expanded following feedback from GBD 2013 and input from GBD 2015 collaborators. Three risks were added to the list for GBD 2017.

Section 1.5: List of abbreviations

APCSC: Asia-Pacific Cohort Studies Collaboration

BMI: body-mass index

BMD: bone mineral density

CKD: chronic kidney disease

COD: causes of death

CODEm: cause of death ensemble modelling

COPD: chronic obstructive pulmonary disease

CSA: childhood sexual abuse

CSMR: cause-specific mortality rate

CRA: comparative risk assessment

CVD: cardiovascular disease

DALY: disability-adjusted life-year

DHS: Demographic and Health Survey

DRI: data representativeness index

EMR: excess mortality rate

FAO: Food and Agriculture Organization

FPG: fasting plasma glucose

GATHER: Guidelines for Accurate and Transparent Health Estimates Reporting

GBD: Global Burden of Disease

GoF: goodness of fit

ID: Iron deficiency

IDA: Iron deficiency anaemia

IER: integrated exposure response

IHD: ischemic heart disease

ILO: International Labour Organization

IPV: intimate partner violence

JMP: Joint Monitoring Project

LDI: lag distributed income per capita

LMIC: Low and Middle-Income Countries

LRI: lower respiratory infection

MCMC: Markov Chain Monte Carlo simulations

MDG: Millennium Development Goal

MICS: Multiple Indicator Cluster Surveys

MoM: method of moments

NCD: non-communicable disease

OER: observed-to-expected ratio

PAF: population attributable fraction

PDF: probability density function

$PM_{2.5}$: particulate matter <2.5 μm in diameter

PSC: Prospective Cohort Study

RCT: randomised controlled trial

REDCap: Research Electronic Data Capture

RMSE: root mean square error

RR: relative risk

SBP: systolic blood pressure

SD: standard deviation

SDG: sustainable development goal

SDI: Socio-demographic Index

SEER: Surveillance, Epidemiology, and End Results Program

SEV: summary exposure value

SIR: smoking impact ratio

SSB: sugar-sweetened beverages

ST-GPR: spatiotemporal Gaussian process regression

TB: tuberculosis

TMREL: theoretical minimum-risk exposure level

TSNA: tobacco-specific nitrosamines

UI: uncertainty interval

WCRF: World Cancer Research Fund

WHO: World Health Organization

YLD: years lived with disability

YLL: years of life lost

Section 1.6: GBD results overview

Results from the Global Burden of Disease Study (GBD 2017) are now measured in terabytes. Results are available in an interactive data downloading tool on the Global Health Data exchange (GHDx). Data and underlying code used for this analysis will be made publicly available pending manuscript acceptance.

The current version of the data download tool is available in the GHDx and contains core summary results for the GBD 2017: http://ghdx.healthdata.org/gbd-results-tool. The core summary results include deaths, YLLs, years lived with disability (YLDs), and disability-adjusted life-years (DALYs). The GHDx includes data for causes, risks, cause-risk attribution, aetiologies, and impairments.

In the GBD 2017 version, the GHDx tool also contains measures such as prevalence and incidence as well as rate of change data. Data above a certain size cannot be viewed online but can be downloaded. Depending on the size of the download, users may need to enter an email address; a download location will be sent to them when the files are prepared.

Section 1.7: Data input sources overview

GBD 2017 incorporated a large number and wide variety of input sources to estimate mortality, causes of death and illness, and risk factors for 195 countries and territories from 1990-2017. These input sources are accessible through an interactive citation tool available in the GHDx.

Users can retrieve citations for a specific GBD component, cause or risk, and location by choosing from the available selection boxes. They can then view and access GHDx records for input sources and export a CSV file that includes the GHDx metadata, citations, and information about where the data were used in GBD. Additional metadata for each input source are available through the citation tool, as required by the GATHER statement.

The citation tool is accessible through the GHDx at http://ghdx.healthdata.org/gbd-2016/data-input-sources.

Section 1.8: Funding Sources

Research reported in this publication was supported by the Bill & Melinda Gates Foundation, the National Institute on Aging of the National Institutes of Health (award P30AG047845), and the National Institute of Mental Health of the National Institutes of Health (award R01MH110163). The content is solely the responsibility of the authors and does not necessarily represent the official views of the Bill & Melinda Gates Foundation or the National Institutes of Health.

Section 2: Risk factor estimation

Section 2.1: Overview

The comparative risk assessment (CRA) conceptual framework was developed by Murray and Lopez,[1] who established a causal web of hierarchically organised risks or causes that contribute to health outcomes, which allows for quantification of risks or causes at any Level in the framework. In GBD 2017, as in previous iterations of the GBD study, we evaluated a set of behavioural, environmental and occupational, and metabolic risks, where risk-outcome pairs were included based on evidence rules (see Section 2.2.1). These risks were organised in four hierarchical Levels, where Level 1 represents the overarching categories (behavioural, environmental and occupational, and metabolic) nested within Level 1 risks; Level 2 contains both single risks and risk clusters (such as child and maternal malnutrition); Level 3 contains the disaggregated single risks from within Level 2 risk clusters (such as low birthweight and short gestation); and Level 4 details risks with the most granular disaggregation, such as for specific occupational carcinogens, the subcomponents of child growth failure (stunting, wasting, underweight), and suboptimal breastfeeding (discontinued and non-exclusive breastfeeding). At each level of risk, we evaluated whether risk combinations were additive, multiplicative, or shared common pathways for intervention. This approach allows the quantification of the proportion of risk-attributable burden shared with another risk or combination of risks and the measurement of potential overlaps between behavioural, environmental and occupational, and metabolic risks. To date in the GBD we have not quantified the contribution of other classes of risk factors illustrated in Appendix Table 3. We do provide some insights into the potential magnitude of distal social, cultural, and economic factors through an analysis of the relationship between risk exposures and development measured using the Socio-demographic Index (SDI) (see Appendix Section 2.9).

Two types of risk assessments are possible within the CRA framework: attributable burden and avoidable burden. Attributable burden is the reduction in current disease burden that would have been possible if past population exposure had shifted to an alternative or counterfactual distribution of risk exposure. Avoidable burden is the potential reduction in future disease burden that could be achieved by changing the current distribution of exposure to a counterfactual distribution of exposure. Murray and Lopez identified four types of counterfactual exposure distributions: (1) theoretical minimum risk; (2) plausible minimum risk; (3) feasible minimum risk; and (4) cost-effective minimum risk.[2] The theoretical minimum risk level (TMREL) is the level of risk exposure that minimises risk at the population level, or the level of risk that captures the maximum attributable burden. Other possible forms of risk quantification include plausible minimum risk – which reflects the distribution of risk that is conceivably possible and would minimise population-level risk if achieved – while feasible minimum risk describes the lowest risk distribution that has been attained within a population, and the cost-effective minimum risk is the lowest risk distribution for a population that can be attained in a cost-effective manner. Because no robust set of forecasts for all components of GBD is available, in this study we focus on quantifying attributable burden using the theoretical minimum risk counterfactual distribution. Appendix Table 3 shows the eight possible types of risk quantification within the CRA framework, with the hatched box representing the type of CRA currently undertaken by the GBD study. As per the definition of avoidable burden, risk reversibility would be incorporated into this type of assessment, as it would involve reducing risk to the counterfactual for the index year, given a history of past risk exposure. Given the focus in this study on attributable burden, risk reversibility is not a criteria used in estimation here.

In general, this analysis follows the CRA methods used since GBD 2015.[3] The methods described here provide a high-level overview of the analytical logic with a focus on areas of notable change from the methods employed in GBD 2015. Here we aim to provide sufficient detail on the methodology and overall structure of the estimation process. This study complies with the GATHER recommendations proposed by the World Health Organization (WHO) and others, which include recommendations on documentation of data sources, estimation methods, and statistical analysis (Appendix Table 1).[4]

Section 2.2: Step 1. Effect size estimation

Section 2.2.1: Collate relative risk data

Criteria for inclusion of risk-outcome pairs

In this study, as in GBD 2016, we have included risk-outcome pairs that we have assessed as meeting the World Cancer Research Fund (WCRF) grades of convincing or probable evidence.[5] In this framework, convincing evidence consists of biologically plausible associations between exposure and disease established from multiple epidemiological studies in different populations. Evidentiary studies must be substantial, include prospective observational studies, and where relevant, randomised controlled trials (RCTs) of sufficient size, duration, and quality, and showing consistent effects. Probable evidence is similarly based on epidemiological studies with consistent associations between exposure and disease, but for which shortcomings in the evidence exist, such as insufficient trials (or prospective observational studies) available.

The World Cancer Research Fund grading system

Convincing evidence

Evidence based on epidemiological studies showing consistent associations between exposure and disease, with little or no evidence to the contrary. The available evidence is based on a substantial number of studies including prospective observational studies and where relevant, randomised controlled trials of sufficient size, duration, and quality showing consistent effects. The association should be biologically plausible.

Probable evidence

Evidence based on epidemiological studies showing fairly consistent associations between exposure and disease, but for which there are perceived shortcomings in the available evidence or some evidence to the contrary, which precludes a more definite judgment. Shortcomings in the evidence may be any of the following: insufficient duration of trials (or studies); insufficient trials (or studies) available; inadequate sample sizes; or incomplete follow-up. Laboratory evidence is usually supportive. The association should be biologically plausible.

Possible evidence

Evidence based mainly on findings from case-control and cross-sectional studies. Insufficient randomised controlled trials, observational studies, or non-randomised controlled trials are available. Evidence based on non-epidemiological studies, such as clinical and laboratory investigations, is supportive. More trials are needed to support the tentative associations, which should be biologically plausible.

Insufficient evidence

Evidence based on findings of a few studies which are suggestive, but insufficient to establish an association between exposure and disease. Little or no evidence is available from randomised controlled trials. More well designed research is needed to support the tentative association.

Causal criteria

As in GBD 2015 and 2016, to be more objective, consistent, and transparent in our evaluation of the causal relationship, we summarized epidemiologic evidence supporting causality for each risk-outcome pair (Appendix Table 4 and Appendix Table 5). For each pair, we collected data on the following domains:

Domains	*Description*
RCTs of disease endpoint	Number of independent RCTs evaluating the effect of the risk on the disease endpoint
	Percent of independent RCTs showing significant effect in the opposite direction
	Percent of independent RCTs showing no effect
Prospective observational studies of disease endpoint	Number of independent prospective observational studies evaluating the association of the risk with the disease endpoint
	Percent of independent prospective observational studies with significant association in the opposite direction
Strength	Lower Limit of relative risk (RR) in observational studies> 1.5 (Yes/No)
Dose response	Evidence of the dose-response relationship between the risk and the outcome (Yes/No)
Biologic plausibility	Potential biologic mechanism that could explain the effect of the risk on the disease endpoint (Yes/No)
Analogy	Evidence on the relationship between the risk factor and a disease endpoint from the same category (Yes/No)

For risk-outcome pairs with less than five prospective studies, we summarized evidence from case-control studies as well including (a) the number of independent case-control studies evaluating the association of the risk with the disease endpoint and (b) percent of independent case control studies with significant association in the opposite direction.

Section 2.2.2: Determine relative risks

Effect size estimation

The relative risk by level of exposure, or by cause, for mortality or morbidity can be found in published and unpublished primary studies or in secondary studies that summarize relative risks. In Step 1a of the analytical process (Appendix Figure 1), we collated information from randomised controlled trials, cohort, pooled cohort, and case-control studies, and in Step 1b, used these data to determine the relative risk for the risk-outcome pairs included in GBD 2017 (Appendix Table 6). For most risks, data from pooled cohorts, or meta-analyses of cohorts, were used; in the case of the risk of cataracts from household air pollution, cohort data were not available, and instead we used case-control data. We estimated relative risks of mortality and morbidity for 65 risk factors for which we determined attributable burden using relative risk and exposure. We incorporated relative risks from studies that controlled for confounding but not for factors along the causal pathway between exposure and

outcome. For risk-outcome pairs with evidence available for only one of mortality or morbidity, we generally assumed that the estimated relative risks applied equally to both. Given evidence of statistically different relative risks for mortality and morbidity, we incorporated different relative risks for each. We did not find that relative risks were consistently higher or lower for mortality compared with morbidity. Details and citation information for the data sources used for relative risks are provided in searchable form through a new web-tool (http://ghdx.healthdata.org/). Available data sources for determining relative risks varied across risks. Details on how relative risks were calculated for each risk can be found in Appendix Section 4: Risk-specific estimates.

For all outcomes related to unsafe sex, the relative risk and exposure framework was not used to estimate attributable burden. For unsafe sex and HIV, we used a direct attribution approach to address the lack of data on unsafe sexual practices in most populations. The proportion of HIV attributable to unsafe sex was modelled directly using DisMod-MR 2.1 from data on the fraction of cases identified as being through sexual transmission, intravenous drug use, or blood transfusion.

For risks estimated from a continuous exposure distribution where the effect size was reported by categories in pooled or meta-analysis studies, we converted those categories to relative risk per unit increase in exposure. This implies a linear increase in the log of the relative risk and exposure; various studies have suggested this is a reasonable approximation of the dose-response curve for many risks. An example of this is high systolic blood pressure, where data from the Prospective Cohort Study (PSC) and the Asia-Pacific Cohort Studies Collaboration (APCSC) were well-described by a linear increase in the logarithm of the relative risk by a 10-unit increase in high systolic blood pressure. This approximately log-linear relationship suggests that the proportional difference in the age-specific risk of stroke death associated with a given absolute difference in exposure is about the same at all levels of risk. Many meta-analyses convert relative risks to per unit increase for convenience, particularly when studies choose different categories that could not otherwise be compared. The log-linear approximation appears plausible[6] even where there is limited consensus on the appropriate TMREL. Where there were insufficient samples in the primary studies at high levels of exposure to inform the shape of the tail of the distribution, we applied a cap to the maximum relative risk using the midpoint of the last category for which a relative risk was reported.

Section 2.3: Step 2. Exposure estimation

Section 2.3.1: Collate exposure data

Systematic reviews

For GBD 2017, we conducted systematic literature reviews for 23 risks. For other risk factors, only a small fraction of the existing data appears in the published literature and other sources predominate such as survey data and satellite data. Data were systematically screened from household surveys archived in the Global Health Data Exchange (ghdx.healthdata.org), including Demographic and Health Surveys, Multiple Indicator Cluster Surveys, Living Standards Measurement Surveys, and Reproductive Health Surveys. Other national health surveys were identified based on survey series that had yielded usable data for past rounds of GBD, sources suggested to us by in-country collaborators, and surveys identified in major multinational survey data catalogues, such as the International Household Survey Network and the WHO Central Data Catalog, as well as through country Ministry of Health and Central Statistical Office websites. Citations for all data sources used for risk factor estimation in GBD 2017 are

provided in searchable form through a web-tool (http://ghdx.healthdata.org/). A description of the search terms employed for risk-specific systematic reviews are detailed by cause in Appendix Section 4.

Information on systematic reviews were managed using Research Electronic Data Capture (REDCap) electronic data capture tools hosted at the University of Washington.[7] REDCap is a secure, web-based application designed to support data capture for research studies, providing 1) an intuitive interface for validated data entry; 2) audit trails for tracking data manipulation and export procedures; 3) automated export procedures for seamless data downloads to common statistical packages; and 4) procedures for importing data from external sources

Search terms

Search terms for updates of systematic reviews for GBD 2017 are shown by risk in Appendix Section 4.

Survey data preparation

For GBD 2017, survey data constitutes a substantial part of the underlying data used in the estimation process. During extraction, we concentrate on demographic variables (such as location, gender, age), survey design variables (such as sampling strategy and sampling weights), and the variables used to define the population estimate (such a prevalence or a proportion) and a measure of uncertainty (standard error, confidence interval or sample size and number of cases).

Section 2.3.2: 2b. Adjust exposure data

A number of adjustments were applied to extracted exposure sources in order to make the data more consistent and suitable for modelling. Commonly applied adjustments included age-sex splitting, adding study-level covariates, and bias correction. Age-sex splitting was applied to literature data reported by age or sex but not by age and sex assuring that the total number of cases remained as reported. If a source did not report sample size by age or sex, we applied the age-sex distribution of the population for the same location and year to the reported total sample size. We relied on the metaregression component of DisMod-MR 2.1 for most of the bias correction of data for variations in study attributes such as case definitions and measurement method. DisMod-MR 2.1 calculates a single adjustment that is applied regardless of age, sex, or location. If enough data were available to differentiate these adjustments by age, sex, or location, or if detailed survey data were available to make more precise adjustments between different thresholds on a biochemical measure, we applied bias corrections to the data before entry into DisMod-MR 2.1.

Section 2.3.3: 2c. Estimate exposure

Mean exposure estimation

In Step 2a of the estimation process, we used systematic literature reviews to identify risk factor exposure studies published or identified since GBD 2016 and combined these with existing data from household and health examination surveys, census, morbidity, or satellite imagery and ground sensor data (used for estimation of $PM_{2.5}$ [particulate matter <2.5 μm in diameter]). Certain risks, such as diet and alcohol consumption, also incorporated administrative record systems. Data sources used in estimating risk factor exposure can be accessed through the data source tool at http://ghdx.healthdata.org/.

Once data were collected and compiled, step 2b of the analytical flowchart describes the adjustments applied, where necessary, to correct for bias. Examples of these adjustments include: use of urban studies for lead; crosswalks between different measurements, methods, and definitions, such as for self-

report of obesity and glycated haemoglobin (HbA1C) for diabetes; and age-sex splitting of data, such as for fasting plasma glucose, cholesterol, and systolic blood pressure that may be reported from broad age-groups.

For the GBD, we developed two modelling approaches, a Bayesian meta-regression model (DisMod-MR 2.1) and a spatiotemporal Gaussian process regression model (ST-GPR), to pool data from different sources, control and adjust for bias in data, and incorporate other types of information such as country-level covariates. DisMod-MR 2.1 and ST-GPR are mixed effect models that borrow information across age, time, and locations to synthesise multiple data sources into unified estimates of levels and trends. A detailed description of the likelihood used for estimation, and a full description of improvements made for DisMod-MR 2.1, are detailed by Vos and colleagues[8] with additional detail in the appendix to that paper. The ST-GPR model has three main hyper-parameters that control for smoothing across time, age, and location. Values for these hyper-parameters were selected based on cross-validation. Cross-validation tests were conducted for different combinations of the hyper-parameters for three types of models: one data-sparse model, one data-moderate model, and one data-dense model. In each test, 20% of the data were held out and the performance of each combination of hyper-parameters evaluated on the held out data. For each hyper-parameter combination, 10 cross-validation tests were conducted. The performance of each model in predicting the withheld 20% of the data was evaluated using a combined measure based on root mean square error (RMSE) and uncertainty interval coverage. A detailed description of the ST-GPR process regression can be found below in Appendix Section 2.3.3.

The main difference between these methods is their power to include unstructured types of data by sex and age group and in their degree of flexibility. Step 2c in Appendix Figure 1 outlines the use of DisMod-MR 2.1 for 10 risk factors where data were available by different age intervals or mixed sex groups; DisMod-MR 2.1 is the preferred tool in these cases because of its ability to integrate over age and adjust for different exposure definitions in the data; however, the use of Bayesian Markov Chain Monte Carlo (MCMC) simulations with large volumes of data renders the analysis computationally intensive and reduces the number of iterations that are possible. If large volumes of standard age-group data are available – as is generally the case for metabolic risks – using ST-GPR becomes the preferred approach.

In some cases, we adapted our methods of modelling exposure to risks where necessary to account for complexities in the risk-outcome relationship or the need for particular handling of data, for example, dietary risks and ambient air pollution (see Appendix Section 4 for more detail). A complete list of risks and the analytical method used is reported in Appendix Table 2. Additional details for adjustments or adaptations to particular risk models are located in Appendix Section 4.

DisMod-MR 2.1 Estimation

DisMod-MR 2.1 description

Until GBD 2010, nonfatal estimates in burden of disease assessments were based on a single data source on prevalence, incidence, remission or a mortality risk selected by the researcher as most relevant to a particular location and time. For GBD 2010, we set a more ambitious goal: to evaluate all available information on a disease that passes a minimum quality standard. That required a different analytical tool that would be able to pool disparate information presented in varying age groupings and from data sources using different methods. The DisMod-MR 1.0 tool used in GBD 2010 evaluated and pooled all available data, adjusted data for systematic bias associated with methods that varied from the reference and produced estimates by world regions with uncertainty intervals using Bayesian statistical methods.

For GBD 2013, the improved DisMod-MR 2.0 had increased computational speed allowing computations that were consistent between all disease parameters at the country rather than region Level. The hundred-fold increase in speed of DisMod-MR 2.0 was partly due to a more efficient rewrite of the code in C++ but also by changing to a model specification using log rates rather than a negative binomial model used in DisMod-MR 1.0. In cross-validation tests, the log rates specification worked as well or better than the negative binomial specification.[9] For GBD 2015, we rewrote the 'wrapper' code that organizes the flow of data and settings at each level of the analytical cascade. The sequence of estimation occurs at five Levels: global, super-region, region, country and, where applicable, subnational location. The super-region priors are generated at the global Level with mixed-effects, nonlinear regression using all available data; the super-region fit, in turn, informs the region fit, and so on down the cascade. The wrapper gives analysts the choice to branch the cascade in terms of time and sex at different levels depending on data density. The default used in most models is to branch by sex after the global fit but to retain all years of data until the lowest Level in the cascade. Appendix Figure 2 summarizes the DisMod-MR process.

In updating the 'wrapper,' we consolidated the code base into a single language, Python, to make the code more transparent and efficient and to better deal with subnational estimation. The computational engine is limited to three levels of random effects; we differentiate estimates at the super-region, region and country Level. In GBD 2013, the subnational units of China, the UK and Mexico were treated as 'countries' such that a random effect was estimated for every location with contributing data. However, the lack of a hierarchy between country and subnational units meant that the fit to country data contributed as much to the estimation of a subnational unit as the fits for all other countries in the region. We found inconsistency between the country fit and the aggregation of subnational estimates when the country's epidemiology varied from the average of the region. Adding an additional level of random effects required a prohibitively comprehensive rewrite of the underlying DisMod-MR engine. Instead, we added a fifth layer to the cascade, with subnational estimation informed by the country fit and country covariates, plus an adjustment based on the average of the residuals between the subnational location's available data and its prior. This mimicked the impact of a random effect on estimates between subnationals.

In GBD 2015, we also improved how country covariates differentiate nonfatal estimates for diseases with sparse data. The coefficients for country covariates are re-estimated at each Level of the cascade. For a given location, country coefficients are calculated using both data and prior information available for that location. In the absence of data, the coefficient of its parent location is used, in order to utilize the predictive power of our covariates in data sparse situations.

For GBD 2016, the computational engine (DisMod-MR 2.1) remained substantively unchanged from GBD 2015. We changed the prediction year set to generate fits for the years 1990, 1995, 2000, 2005, 2010, and 2016. We updated the age prediction sets to include age groups 80-84, 85-89, 90-94, and 95+, to comply with changes across all functional areas of the GBD. We also expanded the set of locations where subnational units are modelled; the set now includes: Brazil, China, England, India, Indonesia, Japan, Kenya, Mexico, Saudi Arabia, South Africa, Sweden, and the United States.

In GBD 2017, we continued to use DisMod-MR 2.1, as there were no substantial changes. Updates to computation include extending the terminal prediction year to 2017 and additional subnational units in

Ethiopia, Iran, New Zealand, Norway, and Russia. Saudi Arabia was also modelled only at the national level in 2017.

The flowchart for the DisMod-MR 2.1 process can be found in Appendix Figure 2.

DisMod-MR 2.1 likelihood estimation

Analysts have the choice of using a Gaussian, log-Gaussian, Laplace or Log-Laplace likelihood function in DisMod-MR 2.1. The default log-Gaussian equation for the data likelihood is:

$$-log\left[p\left(y_j|\Phi\right)\right] = \log\left(\sqrt{2\pi}\right) + \log\left(\delta_j + s_j\right) + \frac{1}{2}\left(\frac{\log\left(a_j + \eta_j\right) - \log\left(m_j + \eta_j\right)}{\delta_j + s_j}\right)^2$$

where, y_j is a 'measurement value' (i.e., data point); Φ denotes all model random variables; η_j is the offset value, eta, for a particular 'integrand' (prevalence, incidence, remission, excess mortality rate, with-condition mortality rate, cause-specific mortality rate, relative risk or standardized mortality ratio) and a_j is the adjusted measurement for data point j, defined by:

$$a_j = e^{(-u_j - c_j)} y_j$$

where u_j is the total 'area effect' (i.e., the sum of the random effects at three Levels of the cascade: super-region, region and country) and c_j is the total covariate effect (i.e., the mean combined fixed effects for sex, study level and country level covariates), defined by:

$$c_j = \sum_{k=0}^{K[I(j)]-1} \beta_{I(j),k} \hat{X}_{k,j}$$

with standard deviation

$$s_j = \sum_{l=0}^{L[I(j)]-1} \zeta_{I(j),l} \hat{Z}_{k,j}$$

where k denotes the mean value of each data point in relation to a covariate (also called x-covariate); I(j) denotes a data point for a particular integrand, j; $\beta_{I(j),k}$ is the multiplier of the k^{th} x-covariate for the i^{th} integrand; $\hat{X}_{k,j}$ is the covariate value corresponding to the data point j for covariate k; l denotes the standard deviation of each data point in relation to a covariate (also called z-covariate); $\zeta_{I(j),k}$ is the multiplier of the l^{th} z-covariate for the i^{th} integrand; and δ_j is the standard deviation for adjusted measurement j, defined by:

$$\delta_j = log\left[y_j + e^{(-u_j - c_j)}\eta_j + c_j\right] - log\left[y_j + e^{(-u_j - c_j)}\eta_j\right]$$

Where m_j denotes the model for the j^{th} measurement, not counting effects or measurement noise and defined by:

$$m_j = \frac{1}{B(j) - A(j)} \int_{A(j)}^{B(j)} I_j(a)\, da$$

where A(j) is the lower bound of the age range for a data point; B(j) is the upper bound of the age range for a data point; and I_j denotes the function of age corresponding to the integrand for data point j.

Spatiotemporal Gaussian process regression

Spatiotemporal Gaussian process regression (ST-GPR) has been used for risk factors where the data density is sufficient to estimate a very flexible time trend. The flowchart showing the analytic steps can be found in Appendix Figure 3. The approach is a stochastic modelling technique that is designed to detect signals amidst noisy data. It also serves as a powerful tool for interpolating non-linear trends.[10,11] Unlike classical linear models that assume that the trend underlying data follows a definitive functional form, GPR assumes that the specific trend of interest follows a Gaussian Process, which is defined by a mean function $m(\cdot)$ and a covariance function $Cov(\cdot)$. For example, let $p_{c,a,s,t}$ be the exposure, in normal, log, or logit space, observed in country *c*, for age group *a*, and sex *s* at time t:

$$\left(p_{c,a,s,t}\right) = g_{c,a,s}(t) + \epsilon_{c,a,s,t}$$

where

$$\epsilon_{c,a,s,t} \sim Normal\left(0, \sigma_p^2\right),$$

$$g_{c,a,s}(t) \sim GP\left(m_{c,a,s}(t), Cov\left(g_{c,a,s}(t)\right)\right).$$

The derivation of the mean and covariance functions, $m_{c,a,s}(t)$ and $Cov\left(g_{c,a,s}(t)\right)$, along with a more detailed description of the error variance (σ_p^2), is described below.

Estimating mean functions

We estimated mean functions using a two-step approach. To be more specific, $m_{c,a,s}(t)$ can be expressed, depending on the exposure transformation, as:

$$log\left(p_{c,a,s}(t)\right) = X_{c,a,s}\beta + h(r_{c,a,s,t})$$

$$logit\left(p_{c,a,s}(t)\right) = X_{c,a,s}\beta + h(r_{c,a,s,t})$$

$$p_{c,a,s}(t) = X_{c,a,s}\beta + h(r_{c,a,s,t})$$

where $X\beta$ is the summation of the components of a hierarchical mixed-effects linear regression, including the intercept and the product of covariates with their corresponding fixed effect coefficients. Some models were run as hierarchical mixed-effects linear regressions, with random effects on the levels of the geographic hierarchy. For most mixed-effects models, random effects were only used in the fit, not in the prediction. The second part of the equation, $h(r_{c,a,s,t})$, is a smoothing function for the residuals, $r_{c,a,s,t}$, derived from the linear model.[3] Descriptions of exposure transformations and which covariates were used in linear models can be found in Appendix Section 4, which described the risk-specific estimation approaches. Some models used a custom stage-1 estimate – these risks will have detailed information on their mixed-effect estimation process in the risk-specific appendix sections.

While the linear component captures the general trend in exposures over time, much of the data varaibility may still not be adequately accounted for. To address this, we fit a locally weighted polynomial regression (LOESS) function $h(r_{c,a,s,t})$ to systematically estimate this residual variability by

borrowing strength across time, age, and space patterns (the spatiotemporal component of ST-GPR).[12,13] The time adjustment parameter, defined by λ , aims to borrow strength from neighboring time points (i.e. the exposure in this year is highly correlated with exposure in the previous year but less so further back in time). The age adjustment parameter, defined by ω, borrows strength from data in neighboring age groups. The space adjustment parameter, defined by ξ, aims to borrow strength across the hierarchy of geographical locations. This year, we further combined the spatial and temporal weights into a single space-time weight, to allow the amount of spatial weight given to a particular point $r_{c,a,s,t}$ to fluctuate given the data availability at each time *t* and location-level *l* in the location hierarchy.

Let $w_{c,a,s,t}$ be the final weight assigned to observation $r_{c,a,s,t}$ with reference to a focal observation r_{c_0,a_0,s_0,t_0}. We first generated a temporal weight $t.w_{c,a,s,t}$ for smoothing over time, which was based on the scaled distance along the time dimension of the two observations[14]:

$$t.w_{c,a,s,t} = \frac{1}{e^{\lambda|t-t_0|}}$$

Next, we generated a spatial weight to smooth over geography. Specifically, we defined a geospatial relationship by categorizing data based on the GBD location hierarchy (Appendix Table 7).

In previous GBD iterations, a vector of spatial weights corresponding to each level of the location hierarchy was derived as $[\xi, \xi*(1-\xi)^{n_1-1}, \ldots, \xi*(1-\xi)^{n_i-1}, (1-\xi)^{n_i}]$, where n_i, designated the number of location levels in between the given location and the global level and ζ was typically between .7 - .99. Under the previous spatial weighting system, all country datapoints would receive a weight of ζ, all regional datapoints a weight of ζ *(1- ζ), etc, no matter how much data was available in the country compared to the region. For example, if there was only a single datapoint for a given country and ζ was set to .7 , that lone datapoint would receive 70% of the spatial weight.

This year, we reformulated zeta to act as a scalar on a given datapoint given its proximity to the target location:

$$t.w_{c,a,s,t} = \zeta^{|c-c_0|}$$

For example, estimating a country would use the following weighting scheme:

- Country data: ζ^0 = 1
- Regional data not from the country being estimated: ζ^1
- Data from other regions in the same super region: ξ^2
- Global data from other super regions: ζ^3

Under the new spatial weighting specification, typical values of ζ range from [.001, .2], where ζ can be interpreted as the amount to downweight regional datapoints compared to country datapoints for a given estimating country. For example, for a given datapoint $r_{c,a,s,t}$ and ζ = .01, a datapoint not within country *c* but within the same region *r* as $r_{c,a,s,t}$ would be assigned $\frac{1}{100}$ the weight of a datapoint within the country.

The spatial and temporal weights were then multiplied and summed across each level of the location hierarchy, and normalized for each time period *t* . This allows the space-time weight to implicitly take

into account the amount of data available at the country vs. region vs super-region level and attribute spatial weight accordingly.

Given a normalization constant,

$$K_i = \sum_{c \epsilon C} s.w_{c,t} * t.w_{c.t} + \sum_{c \epsilon R} s.w_{c,t} * t.w_{c.t} + \sum_{c \epsilon SR} s.w_{c,t} * t.w_{c.t}$$

the final space-time weight would then equal

$$w'_{c,a,s,t} = \frac{s.w_{c,t} * t.w_{c,t}}{K_i}$$

Finally, we calculated the weight $w''_{c,a,s,t}$ to smooth over age, which is based on a distance along the age dimension of two observations. For a point between the age a of the observation $r_{c,a,s,t}$ and a focal observation r_{c_0,a_0,s_0,t_0}, the weight is defined as follows:

$$w''_{c,a,s,t} = \frac{1}{e^{\omega|a-a_0|}}$$

The final weights would then be computed by simply multiplying the space-time weights and age weights and normalizing so all weights for a given time period *t* sum to 1. A full derivation of weights for each category follow, assuming the location being estimated was a country, follows:

1) If the observation $r_{c,t}$ belongs to the same country c_0 of the focal observation r_{c_0,t_0}:

$$w_{c,a,s,t} = \frac{(w'_{c,a,s,t} w''_{c,a,s,t})}{\sum_{c=c_0}(w'_{c,a,s,t} w''_{c,a,s,t})} \qquad \forall c = c_0$$

2) If the observation $r_{c,t}$ belongs to a different country than the focal observation r_{c_0,t_0}, but both belong to the same region R:

$$w_{c,a,s,t} = \frac{(w'_{c,a,s,t} w''_{c,a,s,t})}{\sum_{c \neq c_0}(w'_{c,a,s,t} w''_{c,a,s,t})} \qquad \forall c \neq c_0 \cap R[c] = R[c_0]$$

3) If the observation $r_{c,t}$ belongs to the same super region SR but to a both different country c_0 and region $R[c_0]$ than the focal observation r_{c_0,t_0}:

$$w_{c,a,s,t} = \frac{(w'_{c,a,s,t} w''_{c,a,s,t})}{\sum_{c \neq c_0}(w'_{c,a,s,t} w''_{c,a,s,t})} \qquad \forall c \neq c_0 \cap R[c] \neq R[c_0] \cap SR[c] = SR[c_0]$$

4) If the observation $r_{c,t}$ is from a different super region than the focal observation r_{c_0,t_0}(ie. all other data currently not receiving a weight):

$$w_{c,a,s,t} = \frac{(w'_{c,a,s,t} w''_{c,a,s,t})}{\sum_{c \neq c_0}(w'_{c,a,s,t} w''_{c,a,s,t})} \qquad \forall c \neq c_0 \cap R[c] \neq R[c_0] \cap SR[c] \neq SR[c_0]$$

Observations could be downweighted by a factor of 0.1, usually because they were not geographically representative at the unit of estimation. Details of reasons for downweighting can be found in risk-specific modeling summaries. The final weights were then normalized such that the sum of weights across age, time, and geographic hierarchy for a reference group was 1.

Estimating error variance

σ_p^2 represents the error variance in normal or transformed space including sampling variance of the estimates and prediction error from any crosswalks performed. First, variance was systematically imputed if the data extraction did not include any measure of uncertainty. When some sample sizes for data were available, missing sample sizes were imputed as the 5th percentile of available sample sizes. Missing variances were then calculated as $\sigma_p^2 = \frac{p*(1-p)}{n}$ for proportions or were predicted from the mean using a regression for continuous values. When sample sizes were entirely missing and could not be imputed, the 95th percentile of available variances at the most granular geographic level (ie, first country, then region, etc.) were used to impute missing variances. For proportions where *p*n* or *(1-p)*n* is < 20, variance was replaced using the Wilson Interval Score method.

Next, if the exposure was modelled as a log transformation, the error variance was transformed into log-space using the delta method approximation as follows,

$$\sigma_p^2 \cong \frac{\sigma_{p'}^2}{p_{c,a,s,t}^2}$$

where $\sigma_{p'}^2$ represents the error variance in normal space. If the exposure was modelled as a logit transformation, the error variance was transformed into logit-space using the delta method approximation as follows,

$$\sigma_p^2 \cong \frac{\sigma_{p'}^2}{(p_{c,a,s,t} * (1 - p_{c,a,s,t}))^2}$$

Finally, prior to GPR, an approximation of non-sampling variance was added to the error variance. Calculations of non-sampling variance were performed on normal-space variances. Non-sampling variance was calculated as the variance of inverse-variance weighted residuals from the space-time estimate at a given location level hierarchy. If there were fewer than 10 data points at a given level of the location hierarchy the non-sampling variance was replaced with that of the next highest geography level with more than 10 data points.

Estimating the covariance function

The final input into GPR is the covariance function, which defines the shape and distribution of the trends. Here, we have chosen the Matern-Euclidian covariance function, which offers the flexibility to model a wide spectrum of trends with varying degrees of smoothness. The function is defined as follows:

$$M(t,t') = \sigma^2 \frac{2^{1-v}}{\Gamma(v)} \left(\frac{d(t,t')\sqrt{2v}}{l} \right)^v K_v \left(\frac{d(t,t')\sqrt{2v}}{l} \right)$$

where $d(\cdot)$is a distance function; σ^2, ν, l, and K_ν are hyperparameters of the covariance function—specifically σ^2 is the marginal variance, ν is the smoothness parameter that defines the differentiability of the function, l is the length scale, which roughly defines the distance between which two points become uncorrelated, and K_ν is the Bessel function. We approximated σ^2 by taking the normalized median absolute deviation $MADN(r_c')$ of the difference which is the normalized absolute deviation of the difference of the first-stage linear regression estimate from the second-stage spatiotemporal smoothing step for each country. We then took the mean of these country-level MADN estimates for all countries with 10+ country-years of data, to ensure that differences between first- and second-stage estimates had sufficient data to truly convey meaningful information on model uncertainty. We used the parameter specifications $\nu = 2$ for all models. The scale parameter l used for each risk is reported in Appendix Section 4.

Prediction using GPR

We integrated over $g_{c,t}(t_*)$ to predict a full time series for country c, age a, sex s, and the prediction time t_*:

$$p_{c,a,s}(t_*) \sim N\left(m_{c,a,s,t}(t_*), \sigma_p^2 I + Cov\left(g_{c,a,s,t}(t_*)\right)\right)$$

Random draws of 1000 samples were obtained from the distributions above for every country for a given indicator. The final estimated mean for each country was the mean of the draws. In addition, 95% uncertainty intervals were calculated by taking the 2.5 and 97.5 percentile of the sample distribution. The linear modelling process was implemented using the lmer4 package in R, and the ST-GPR analysis was implemented through the PyMC2 package in Python.

Subnational Scaling and Aggregation

To ensure internal consistency of the estimates between countries and their respective subnational locations, national estimates were either created by population-weighted aggregation or subnational estimates were adjusted by population-weighted scaling to the national estimates, depending on the data coverage of a given country compared to that of its subnational locations. For example, if there was better data coverage at the national level, relative to its corresponding subnational locations, for a given country and risk across age, sex, and time, estimates were rescaled to be consistent with the national level. Conversely, if there was better data coverage at the subnational level, estimates for its parent country were generated through population-weighted aggregation of subnational estimates.

This GBD iteration, we incorporated an option to scale estimates within logit space. Scaling in logit space ensures that subnational estimates of proportion models will not exceed one after being rescaled to the national estimate.

Fitting a distribution to exposure data

The most informative data describing the distribution of risk factors within a population come from individual-level data; additional sources of data include reported means and variances. In cases when a risk factor also defines a disease or disease severity cut-off, such as haemoglobin level and mild, moderate, or severe anaemia or diabetes and fasting plasma glucose, the prevalence of disease is also frequently reported. To model the distribution of any particular risk factor, we seek a family of probability density functions (PDFs), a fitting method, and a model selection criterion. To make use of the most commonly available data describing most populations, we used the method of moments

(MoM); the first two empirical moments from a population, the mean and variance, were used to determine the parameters of two-parameter probability distribution families (PDF) describing the distribution of risk within any population. Exceptions to this rule are justified by context. We used the Kolmogorov-Smirnov[15] (KS) test to measure the goodness of fit (GoF), comparing the distance between the empirical and ensemble distributions, but in some cases, the GoF was based on the prediction error for the prevalence of disease.

We used an ensemble technique in which a model selection algorithm is used to choose the best model for each continuous risk factor.[15] We drew the initial set of candidate models from commonly used PDF families, including both right-skewed and left-skewed distributions. These included: beta, exponential, gamma, gumbel, inverse gamma, inverse Weibull, log-logistic, lognormal, mirrored gamma, mirrored gumbel, normal, and Weibull. We fitted each PDF candidate family to each dataset using the MoM, and used the KS test as the measure of GoF. Preliminary analysis showed that the GoF ranking of PDF families varied across datasets for any particular risk factor and that combining the predictions of differently fitted PDF families could dramatically improve the GoF for each dataset. Therefore, we developed a new model for prediction using the ensemble of candidate models, which is a weighted linear combination of all candidate models, $\{f\}$, where a set of weights $\{w\}$ is chosen such that $\sum_i w_i = 1$, and the values of the weights were determined by a second GoF criterion with its own validation process. For each risk, we pooled all available microdata and performed Nelder-Mead numeric optimisation across demographics subsets of data to derive a set of distribution-specific weights such that the average KS statistic across data sets is minimised. The details can be summarised by 1) the summary statistics for each dataset; 2) a table showing the KS statistic for each candidate model; and 3) the weights defining the final ensemble model for each dataset. We then averaged across demographic subsets and data sets to determine the final weights for modelling the distribution of any particular risk factor.

Section 2.4: Step 3. TMREL

In this and all previous GBD studies, the counterfactual level of risk exposure used is the risk exposure that is both theoretically possible and minimizes risk in the exposed population that consequently captures the maximum population attributable burden.[2] For each risk evaluated in GBD 2017, Step 4 of the analytical flowchart describes the use of the best available epidemiological evidence from published and unpublished relative risks by level of exposure and the lowest observed level of exposure from cohorts, used to select a single level of risk exposure that minimises risk from all causes of DALYs combined to establish the TMREL. In principle, the TMREL for a given risk may vary by age, sex, and location if supported by clear evidence. Based on the available evidence, the TMREL itself can be uncertain, which is reflected in the 95% uncertainty intervals (UIs) in Appendix Table 6. An estimation of uncertainty was derived by resampling from a uniform distribution of TMRELs where evidence supporting the selection of the TMREL was uncertain (for example, elevated systolic blood pressure or cholesterol).

Section 2.5: Step 4. Estimate population attributable fractions

Risks are categorised on the basis of how exposure was measured: dichotomous, polytomous, and continuous. High low-density lipoprotein (LDL) cholesterol is an example of a risk measured on a continuous scale. The population attributable fraction (PAF), which represents the proportion of risk

that would be reduced in a given year if the exposure to a risk factor in the past were reduced to an ideal exposure scenario, is defined for a continuous risk factor as:[16]

$$PAF_{joasgt} = \frac{\int_{x=l}^{u} RR_{joasg}(x)P_{jasgt}(x)dx - RR_{joasg}(TMREL_{jas})}{\int_{x=l}^{u} RR_{joasg}(x)P_{jasgt}(x)dx}$$

Where PAF_{joasgt} is the population attributable fraction for cause o due to risk factor j for age group a, sex s, location g, and year t. $RR_{joasg}(x)$ is the relative risk as a function of exposure level x for risk factor j for cause o, age group a, sex s, and location g with the lowest level of observed exposure as l and the highest as u; $P_{jasgt}(x)$ is the distribution of exposure at x for age group a, sex s, location g, and year t; $TMREL_{jas}$ is the TMREL for risk factor j, age group a, and sex s.

The PAF_{joasgt} for dichotomous and polytomous risk factors for every country is defined as:

$$PAF_{joasgt} = \frac{\sum_{x=1}^{u} RR_{joast}(x)P_{jasgt}(x) - RR_{joasg}(TMRE_{jas})}{\sum_{x=1}^{u} RR_{joas}(x)P_{jasgt}(x)}$$

Where PAF_{joasgt} is the population attributable fraction for cause o due to risk factor j for age group a, sex s, location g, and year t. $RR_{joasg}(x)$ is the relative risk as a function of exposure level x for risk factor j for cause o, age group a, sex s, and location g on a plausible range of exposure levels from l to u $P_{jasgt}(x)$ is the proportion of population in risk group (prevalence), for age group a, sex s, location g, and year t; $TMREL_{jas}$ is the TMREL for risk factor j, age group a, and sex s.

Section 2.6: Step 5. Estimate summary exposure values

Summary exposure value (SEV), is the relative risk-weighted prevalence of exposure, a univariate measure of risk-weighted exposure, taking the value zero when no excess risk for a population exists and the value one when the population is at the highest level of risk. We report SEVs on a scale from 0% to 100% where a decline in SEV indicates reduced exposure to a given risk factor and an increase in SEV indicates increased exposure.

We first calculate risk, r, and cause, c, specific SEVs using the following equation,

$$SEV_{rc} = \frac{\frac{PAF_{rc}}{1 - PAF_{rc}}}{RR_{max} - 1}$$

for each most-detailed age, sex, location, year, and outcome. PAF is the YLL (expect for occupational noise, bullying victimization, and occupational ergonomic factors which are YLD only and thus use the YLD) PAF. RR_{max} for categorical risks is the RR at the highest category of exposure. For continuous risks, this is

$$RR_{max} = RR^{\frac{TMREL - 1^{st} exposure}{RR_{scalar}}}$$ if protective, or

$$= RR^{\frac{99^{th}exposure - TMREL}{RR_{scalar}}}$$

otherwise, and for custom modelled risks like ambient particulate matter pollution, household air pollution from solid fuels (HAP), alcohol, smoking, bullying, and activity, the modeller provides draws of RR_{max}. Generally, RRs do not vary across time and space, however, there are exceptions – an example being those risks such as second-hand smoke (SHS) or HAP where the RR is based on the integrated exposure response [IER], curve) and in these cases the RR is averaged across location and year to ensure no time or space variation. If the PAF is negative, signifying a protective effect for that outcome, the PAF is set to 0 and the SEV is then also 0 as the SEV univariate and constrained to be a value between 0 and 1. Once we have a set of risk cause specific SEVs at the most-detailed risk, cause, age, sex, location for all years, we average across causes to produce the final risk specific SEV_r,

$$SEV_r = \frac{1}{N(c)} \sum_c SEV_{rc}$$

Section 2.7: Step 6. Mediation

Section 2.7.1: Summary

The portion of the burden of disease that is attributable to various combinations of risk factors or to all risk factors combined has been a topic of broad interest.[17] Assumptions about how one risk factor is mediated through other risk factors are needed in order to estimate the joint risk factor burden for combinations of metabolic risks and behavioural or environmental risks. To accomplish this, in Step 6 of the estimation process, for every two risk factors for an outcome, we estimated the fraction of risk that was mediated through the other risk. This resulted in a matrix of parameters containing each possible pairing of risk factors included in the GBD 2017. Using this matrix, we computed the aggregated burden of disease at each level of the GBD 2017 hierarchy and for all risk factors using the following formula:

$$PAF_{Joasgt} = 1 - \prod_{j=1}^{J} \left(1 - PAF_{joasgt} \prod_{i=1}^{J} (1 - MF_{jio}) \right) \quad (5)$$

where J is a set of risk factors for the aggregation; PAF_{joasgt} is the PAF for risk j for age group a, sex s, location g, and year t; and MF_{jio} is the mediation factor for risk j mediated through i for cause o. Mediation factors can be found in Appendix Table 8.

Section 2.7.2: Additional detail

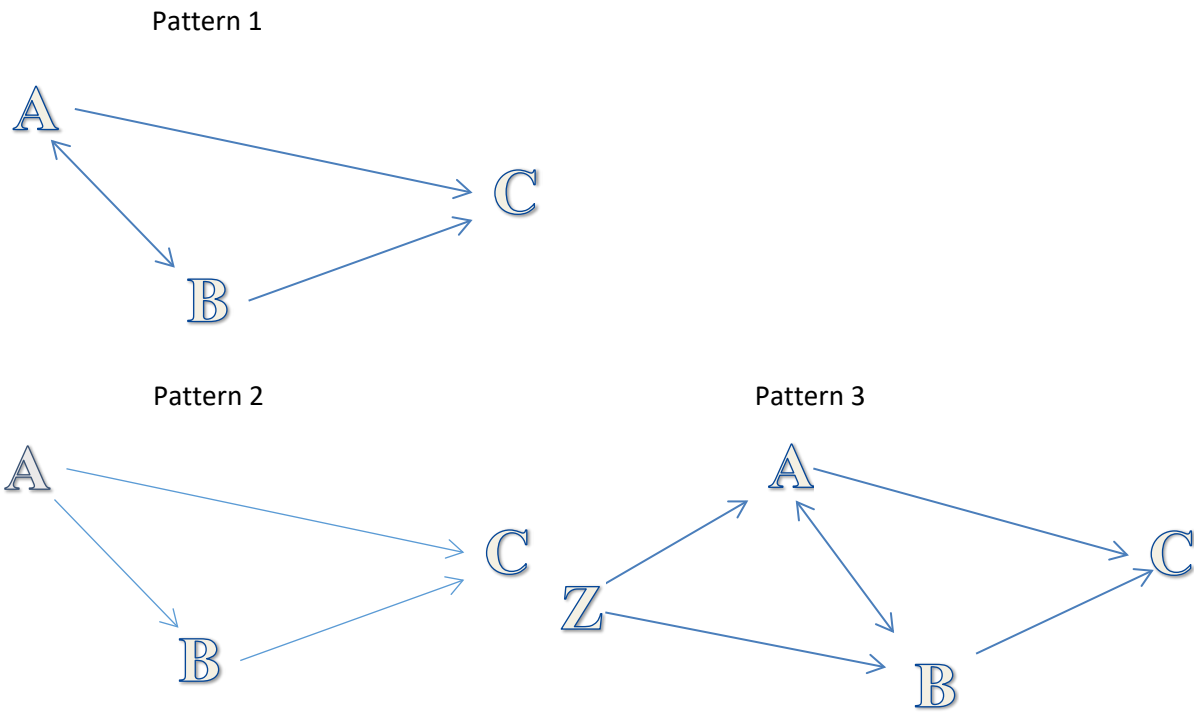
In GBD 2010, we only aggregated the burden of risk factors for some clusters of risks including access to improved water and sanitation, child and maternal malnutrition, tobacco smoking, alcohol use, dietary risk factors, occupational risk factors, and sexual abuse and violence. We did not aggregate air pollution and metabolic risk factors. For GBD 2013, GBD 2015, GBD 2016, and GBD 2017, we aggregated all risk factors into three large categories: behavioural, environmental and occupational, and metabolic risks -- as well as aggregating all GBD risk factors into a single attributable fraction for each diseases and eventually for all-causes of burden.

Aggregating risk factors at different levels share three essential challenges:

1. Risk factor coexistence or aggregation: for example, metabolic risk factors often occur together or high-risk behaviours are related such as drug abuse and unsafe sex.
2. Mediation: a risk factor may effect another risk factor that lies in the physiological pathway to a disease outcome. It can be inside a cluster of risk factors such as the effect of obesity through an increase in fasting plasma glucose (FPG) and later cardiovascular disease outcomes, or between clusters of risk factors such as the effect of fibre on cholesterol.
3. The formula to calculate the aggregated PAF.

The aggregation method is conceptually applicable to other aggregations such as socioeconomic factors, education, homelessness and refugee status that are being considered for inclusion in future GBD iterations. In the next section, we explain our approach to deal with these challenges.

There are three patterns of associations between risk factors to take into consideration. The first concerns confounding; risk B affects risk A and outcome C (Pattern 1 in *Patterns of associations between risk factors*). In these cases, the relative risk (RR) for A should be adjusted for B, for example, the fruit RR is adjusted for smoking. If part of the effect of A is through B, a mediator, we do not adjust the effect of A for B. For example, we do not adjust the RR of body-mass index (BMI) for cholesterol as cholesterol lies in the biological pathway between BMI and cardiovascular outcomes (Pattern 2 in in *Patterns of associations between risk factors*). The third pattern occurs when risks A and B are proxies of a third variable Z and aggregation aims to estimate the total effect of a latent variable Z, on C. An example is child growth failure, which is measured by stunting, wasting, and underweight as proxies.



Patterns of associations between risk factors

Section 2.7.3: Calculating burden of multiple risk factors

Validation studies have reported congruency between the true risk associated with multiple risk factors affecting the same outcome and a multiplicative aggregation of the population attributable fractions of the individual risk factors (formula below).[18]

$$PAF_{1..i} = 1 - \prod_{i=1}^{n}(1 - PAF_i)$$

Where *PAF* is the population attributable fraction and *i* is each individual risk factor. The same validation studies also found that the overestimation from ignoring the covariance between risk factors is small. This was important to note as there are few data sources from which we can draw information on covariance.

We endeavoured to evaluate RRs that were controlled for confounders. However, as we had to rely on the literature for many RRs we did not always have full control over the choice of confounders controlled for in each study.

Section 2.7.4: Adjusting for mediation

When aggregating the effects of multiple risk factors, we included a mediation factor if a part of the effect of one risk factor was included in the effect estimated for in the mediator. First, we prepared a list of possible mediations especially between behavioural risks and metabolic risk factors with cardiometabolic outcomes. We did not assume any mediation effect between risk factors for cancers.

Danaei and colleagues assumed that part of the effect of BMI on ischemic heart disease (IHD) is through high systolic blood pressure (SBP), cholesterol and FPG.[19] The proportion of the BMI effect that can be explained by other metabolic risk factors is the amount of mediation. The difference between the crude RR of BMI on IHD with the RR adjusted for SBP, FPG, and cholesterol reflects the amount of BMI effect on IHD that is mediated and already included in SBP, FPG, and cholesterol:

$$MF = \frac{RR_{crude} - RR_{adjusted}}{RR_{crude} - 1}$$

We used this approach for estimating mediation factors to adjust PAFs before aggregation.

$$MF = \frac{R_c^+ - R_a^+}{R_c^+ - R_c^-}$$

$$\text{So: } R_a^+ = R_c^+ - MF * (R_c^+ - R_c^-)$$

$$PAF_c = \frac{p * (R_c^+ - R_c^-)}{p * R_c^+ + (1-p) * R_c^-} = \frac{p * (R_c^+ - R_c^-)}{R_T}$$

If R_c^+: crude risk of outcome in exposed population

R_c^-: crude risk of outcome in non-exposed population

R_a^+: adjusted risk of outcome in exposed population

R_a^-: adjusted risk of outcome in non-exposed population

R_T is the overall rate of the outcome in the population. Since we are interested in the part which is from BMI but through cholesterol, the total risk in the population will be the same for the adjusted RR, so the unmediated part of the risk factor would be:

$$PAF_a = \frac{p*(R_a^+ - R_a^-)}{R_T} = \frac{p*(R_c^+ - MF*(R_c^+ - R_c^-) - R_c^-)}{R_T} = \frac{p*(R_c^+ - R_c^-)*(1-MF)}{R_T} = PAF_c * (1 - MF)$$

So for aggregating the PAF of multiple risk factors, we first calculated the part of the effect of every risk factor that is not mediated and then aggregated these assuming they are independent.

Therefore the aggregated PAF would be:

If MF is mediation factor of R2 through R1:

$$PAF_{1,2} = 1 - (1 - PAF_1) * \left(1 - PAF_2 * (1 - MF_{2/1})\right)$$

and a generalization for multiple pathways of R1 through other RFs:

$$PAF_{1..i} = 1 - \prod_{i=1}^{n} \left(1 - PAF_i * \left(1 - \prod_{j=1}^{n} (1 - MF_{i/j})\right)\right)$$

For every risk factor outcome pair, the matrix of possible mediations was calculated and used.

Section 2.7.5: Calculating mediation factor

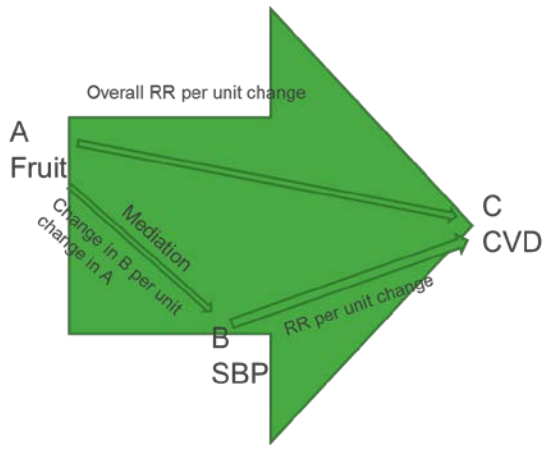
1 – Comparing crude RR versus mediator-adjusted RR

The best example is the mediation of BMI through SBP, FPG, and cholesterol reported by Danaei et al.[19] In their meta-analysis, they report the adjusted and unadjusted RR of BMI on IHD and stroke based on combined data from individual cohorts. They calculated the mediation factor using the equation below, and we used it directly as mediation factor in risk factor aggregation. Using individual level data from cohort studies, we estimated the mediation factor for other metabolic risk factors and some dietary risks.

$$MF = \frac{RR_{crude} - RR_{adjusted}}{RR_{crude} - 1}$$

2 – Estimating the mediation factor by pathway of the effect

For many other risk factors, there are no data available to use the first method. Instead, we searched studies to estimate the effect of the risk factor on the mediator and finally the expected increase in IHD risk. We pooled available studies to calculate the unit increase in the mediator per unit increase in the risk factor to calculate the size of the IHD RR.



Example of pathway between fruit, high systolic blood pressure, and cardiovascular diseases

We have RRs for the effect of A on C and B on C in GBD from a meta-analysis of studies in the literature. The effect of A on B was estimated by analysis of diet trials.

$$RR_{ABC} = {RR_{BC}}^{\Delta_{AB}}$$

RR_{ABC} is expected effect of A through B on C

RR_{BC} is relative risk of each unit increase in mediator on outcome C

Δ_{AB} is change in mediator level B per each unit change in A

If RR_{AB} is the overall effect of A on B then:

The mediation factor would be

$$MF = \frac{RR_{ABC} - 1}{RR_{AB} - 1}$$

We kept uncertainty of each parameter by generating and following 1000 draws of the estimates to calculate 1000 draws of the posterior distribution of the mediation factor. We did not include risk-mediator pairs if the mediation factor was not significant at 5% level (more than 50 out of 1000 draws were negative). We truncated the mediation factor distribution at 1 where the whole effect of the risk factor on the outcome would be assumed to be through the mediator pathway.

Some mediation factors equal 1 where the whole effect was calculated through other risk factor, e.g. the effect of salt through SBP, or when we assumed other risk factors are sources of the exposure, for example, fibre is provided by consuming fruit, vegetable, and whole grains and all the beneficial effect of milk on colorectal cancer is mediated through calcium.

Dietary risk factors

For each dietary risk factor, we searched for randomised trials evaluating the effect of the diet component on metabolic risk factors and estimated the change in a given mediator per unit change in the diet component. Only salt outcomes, with the exception of stomach cancer, are mediated through BMI – all other dietary risk factors have their relative risk applied directly.

Physical activity

We found cohort studies on the effect of physical activity on FPG. The data was more on the effect of physical activity on diabetes incidence, so we calculated the shift in FPG using the provided RR value. We used this to calculate the mediated part of effect of physical activity on cardiovascular disease (CVD).[20–26]

Air pollution

We considered mediation for particulate matter pollution, but the evidence was not strong enough to justify inclusion of $PM_{2.5}$ on SBP, FPG, or cholesterol. There are two cohort studies which have published findings of increased risk of hypertension due to long-term exposure to ambient $PM_{2.5}$ and several studies which have found elevated SPB due to household solid fuel use. We found time series studies with different $PM_{2.5}$ lag (by day) that show very short-term and confounded effects. We decided to re-examine these outcomes when more evidence becomes available.

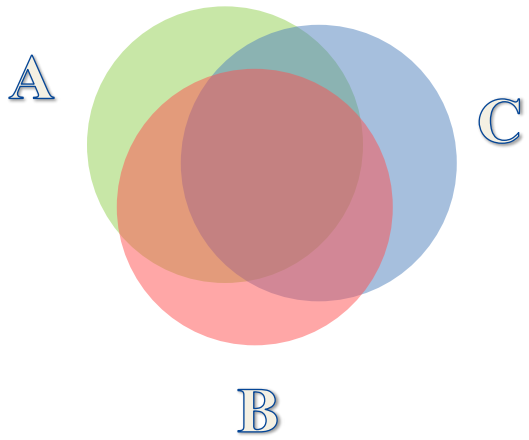
Assumed mediations

For the risk factors with PAFs of 100% such as FPG and diabetes, impaired kidney function and chronic kidney disease, SBP and hypertensive heart disease, alcohol and alcohol use disorders, child underweight and protein-energy malnutrition, and child wasting and protein-energy malnutrition, and drug use and drug use disorders, no mediation is needed.

Section 2.7.6: Piecewise aggregation (Pattern 3)

There are three anthropometric indicators that are highly correlated: child underweight, stunting, and wasting, as demonstrated in *Venn diagram demonstrating the correlation between child underweight, stunting, and wasting*. Available RRs for each indicator are not adjusted for the other two because there is a high correlation between these indicators and also interaction where the majority of the burden occurs. Estimating the total burden due to childe growth failure, a latent variable, is difficult. The three anthropometric indicators are not independent, so the covariance between them should be considered. This was the main reason that GBD 2010 only included child underweight. If covariance between these indicators is significant (as is shown in the Figure below), aggregating these indicators assuming independence would overestimate the total burden significantly.

To use the best available data, we adjusted observed RRs reported by Olofin et al for underweight, stunting and wasting by simulating the joint distribution of the three indicators using the distribution of each indicator and covariance between indicators in the countries included in the meta-analysis (extracted from Demographic and Health Survey (DHS) micro-data).[27] Based on the analysis done by McDonald et al, we assumed there is an interaction between the three indicators, and extracted the interaction terms from the corresponding analysis.[28] We calculated the adjusted RRs by minimizing the error between observed crude RRs (from meta-analysis) and expected crude RRs derived from adjusted RRs.



Venn diagram demonstrating the correlation between child underweight, stunting, and wasting

After adjusting for the three risk factors, we calculated the PAFs and aggregated underweight, stunting and wasting burden.

Section 2.7.7: Uncertainty of aggregated and mediated PAFs

We generated 1000 draws of posterior distribution of mediation factor calculated by different methods to use beside draws of other inputs to the PAF aggregation.

Section 2.7.8: Important assumptions in aggregating risk factors and including mediation

1 – The mediation factors or PAF adjustments are similar across countries, age, sex, and years. While it is quite likely that the size of mediation is different in different populations, there is little data to inform the covariance between different risk factors or the mediation factor amount by age and countries. For example, in some countries, the size of the mediated BMI-IHD PAF through cholesterol, calculated by the mediation factor, was even bigger than the total burden of cholesterol, indicating that less effect of BMI is mediated through cholesterol and mediation factors are not similar across countries.

2 – For many risk-mediator-outcome pairs, there are no data available, so we assumed the mediation is zero.

3 – Since the covariance between undernutrition indicators is different by location (and across time, results were not reported), and there is an interaction between these indicators, the total burden might be underestimated.

4 – It is assumed that there is no significant covariance between PAFs, which might not be true between some risk factors such as between metabolic risk factors. While this overestimation is controlled by using adjusted RRs, using crude RRs for BMI and other metabolic risk factors may cause significant overestimation of aggregated metabolic risks burden.

Section 2.8: Step 7. Estimate attributable burden

Four key components are included in estimation of the burden attributable to a given risk factor: the metric of burden being assessed (the number of deaths, years of life lost [YLLs], years lived with disability [YLDs], or DALYs [the sum of YLLs and YLDs]); the exposure levels for a risk factor; the relative

risk of a given outcome due to exposure; and the counterfactual level of risk factor exposure. Estimates of attributable burden as DALYs for risk-outcome pairs were generated using the following model:

$$AB_{jasgt} = \sum_{o=1}^{w} DALY_{joasgt}\, PAF_{joasgt}$$

where AB_{jasgt} is the attributable burden for risk factor j for age group a, sex s, location g, and year t; $DALY_{joasgt}$ is total DALYs for cause o (of w relevant outcomes for risk factor j) for age group a, sex s, location g, and year t; PAF_{joasgt} is the population attributable fraction (PAF) for cause o due to risk factor j for age group a, sex s, location g, and year t. The proportion of deaths, YLLs, or YLDs attributable to a given risk factor or risk factor cluster were analogously computed by sequentially substituting each metric in place of DALYs in the equation above.

Section 2.9: Decomposition analysis of deaths and DALYs

We conducted a decomposition analysis of changes in DALYs from 2007 to 2017, decomposing changes in all-age cause-specific DALYs attributable to all risk factors and individual risk factors due to changes in population growth, population age structure, exposure to the given risk for a disease, and risk-deleted death and DALY rates. In this case, risk-deleted rates are the rates after removing the effect of a risk factor or combination of risk factors; in other words, observed DALY rates multiplied by one minus the PAF for the risk or set of risks. Our decomposition analyses draw from methods developed by Das Gupta[29] to provide a computationally tractable solution to isolating drivers of burden changes whereby all combinations of possible pathways are averaged across factors. Attributable burden is determined, following the methods of Das Gupta, as a product of three factors such that:

$$T_{asgt} = (A_{asgt}\, B_{asgt}\, C_{asgt})$$

where T_{asgt} represents the attributable burden at year t; $A_{sgt}$is the age-specific population size for a given age group a, sex s and location g at year t; B_{asgt} is the underlying rate of the outcome unrelated to the risk factor or observed rate, multiplied by $1 - PAF$ for a given age group a, sex s and location g at year t; and where C_{asgt} is the ratio of attributable burden to the underlying rate, which reflects the risk exposure effect for a given age group a, sex s, and location g at year t defined as $PAF/(1 - PAF)$ in the case of decomposing attributable burden to a risk. Risk exposure effects for individual risk factors are scaled such that they sum to the all risk exposure effect by location, age, sex, and cause accounting for mediation. This allows for aggregation of risks; the exposure for all risks for a disease can be split into exposure to metabolic, behavioural, and environmental risks. The contribution of each factor to total change in attributable burden was determined by changing the level of one factor from time t_0 to t_1 – here 2007 to 2017 – with all other factors held constant. Thus, the effect of any of the three factors, for example A_{asgt}on the change of attributable burden between 2007 (A_{07}) and 2017 (A_{17}) is calculated as:

$$E_A = (A_{17} - A_{07})\left(\frac{B_{07}C_{07} + B_{17}C_{17}}{3} + \frac{B_{07}C_{17} + B_{17}C_{07}}{6}\right)$$

Where E_A is the proportion of change due to factor A, and the subscripts for each factor in the equation denote the year for each estimate. Since the effect depends on the order of entry of the factor, we calculated the average of all combinations of the three factors.[29] The proportion of change due to factorA_{sgt}, the age-specific population size for a given age group a, sex s and location g at year t, is

then further split, setting change in population growth equal to the percent change in all-age population from time t_0 to t_1 and change in population age structure to the residual, giving four factors.

This three factor decomposition method does not work for risks where the PAF, by definition, is 100% (such as high fasting plasma glucose and diabetes type 2) or where the PAF is directly estimated (such as for unsafe sex and HIV). In the cases of child underweight and protein-energy malnutrition, child wasting and protein-energy malnutrition, short gestation for birth weight and neonatal preterm birth complications, low birth weight for gestation and neonatal preterm birth complications, iron deficiency and iron-deficiency anaemia, alcohol use and liver cancer due to alcohol use, alcohol use and cirrhosis and other chronic liver diseases due to alcohol use, alcohol use and alcohol use disorders, alcohol use and alcoholic cardiomyopathy, drug use and drug use disorders, occupational particulate matter, gases, and fumes and other pneumoconiosis, occupational particulate matter, gases, and fumes and coal workers pneumoconiosis, occupational exposure to asbestos and asbestosis, and occupational exposure to silica and silicosis, we used a two factor decomposition method, which examines the contribution of population, ageing, and risk exposure. Effectively, we assume trends in these cases are driven by exposure, not change in the risk-deleted rates. Conversely, for unsafe sex and sexually transmitted diseases excluding HIV, we used a two-factor decomposition method, which examines the contribution of population, ageing, and risk-deleted death and DALY rates, assuming trends in these cases are driven by risk-deleted rates, not change in exposure. For high fasting plasma glucose and diabetes mellitus type 1 and 2, high fasting plasma glucose and chronic kidney disease due to diabetes mellitus type 1 and 2, high systolic blood pressure and hypertensive heart disease, high systolic blood pressure and chronic kidney disease due to hypertension, and impaired kidney function and chronic kidney disease, we used GBD estimates of Summary Exposure Values (SEVs) for the given risk and the case-fatality rate decompose trends into the contribution of the three factors. Similarly, for unsafe sex and cervical cancer, we used GBD estimates of the incidence of cervical cancer and the case-fatality rate to decompose trends into the contribution of the three factors. For unsafe sex and HIV, we used spectrum counterfactual and CD4 risk-weighted prevalence.

Section 2.10: SDI Analysis

Section 2.10.1:Development of SDI

The Socio-demographic Index (SDI) is a composite indicator of development status strongly correlated with health outcomes. In short, it is the geometric mean of 0 to 1 indices of total fertility rate under the age of 25 (TFU25), mean education for those aged 15 and older (EDU15+), and lag distributed income (LDI) per capita.

Section 2.10.2:Development of revised SDI indicator

SDI was originally constructed for GBD 2015 using the Human Development Index (HDI) methodology, wherein a 0 to 1 index value was determined for each of the original three covariate inputs (total fertility rate in ages 15 to 49, EDU15+, and LDI per capita) using the observed minima and maxima over the estimation period to set the scales.

In response to feedback from collaborators and the evolution of the GBD, we have refined the indicator with each GBD cycle. For GBD 2017, in conjunction with our expanded estimation of age-specific fertility, we chose to replace the total fertility rate as one of the three component indices with the total fertility rate under 25 (TFU25). The TFU25 provides a better measure of women's status in society, as it focuses on ages where childbearing disrupts the pursuit of education and entrance into the workforce.

During GBD 2016, we moved from using relative index scales to absolute scales to enhance the stability of SDI's interpretation over time, as we noticed that the measure was highly sensitive to the addition of subnational units that tended to stretch the empirical minima and maxima. We selected the minima and maxima of the scales by examining the relationships each of the inputs had with life expectancy at birth and under-5 mortality and identifying points of limiting returns at both high and low values, if they occurred prior to theoretical limits (e.g., a TFU25 of 0).

Thus, an index score of 0 represents the minimum level of each covariate input past which selected health outcomes can get no worse, while an index score of 1 represents the maximum level of each covariate input past which selected health outcomes cease to improve. As a composite, a location with an SDI of 0 would have a theoretical minimum level of development relevant to these health outcomes, while a location with an SDI of 1 would have a theoretical maximum level of development relevant to these health outcomes.

We summarize the final scales for GBD 2017 in the table below.

Input	Lower Bound	Upper Bound
TFU25	0	3
LDI per capita	250 USD (5.5 log USD)[b]	60,000 USD (11.0 log USD)
EDU15+	0 years	17 years

[b] The minimum for the LDI scale was originally set at the theoretical limit of 0 USD, as we did not observe an asymptotic relationship between log(LDI) and E_0 or 5q0 at lower values of log(LDI). Empirically, however, we also did not observe an LDI below 350 USD (5.86 log USD) for the estimation period 1970-2016. In log-space, this meant that approximately half of our scale was not being utilized, compressing the observed variation in LDI and diminishing its meaningful contribution to SDI. Accordingly, we set the lower limit on LDI to 250 USD (5.52 log USD) to ensure we were fully utilizing the range of the scale to capture its variation across space and time, as is the case with the other two inputs.

Using scales described above, we computed the index scores underlying SDI as follows:

$$I_{Cly} = {(C_{ly} - C_{low})}\Big/{(C_{high} - C_{low})}$$

Where I_{cly} – the index for covariate *C*, location *l*, and year *y* – is equal to the difference between the value of that covariate in that location-year and the lower bound of the covariate divided by the difference between the upper and lower bounds for that covariate. If the values of input covariates fell outside the upper or lower bounds (e.g. LDI per capita greater than 60,000 USD), they were mapped to the respective upper or lower bounds. We also note that the index value for TFU25 was computed as $1 - I_{TFU25ly}$, as lower TFU25s correspond to higher levels of development, and thus higher index scores. For GBD 2017 we expanded the computation of SDI to 890 national and subnational locations spanning the time period 1950-2017.

The composite Socio-Demographic Index is the geometric mean of these three indices for a given location-year. The cut-off values used to determine quintiles for analysis were then computed using country-level estimates of SDI for the year 2017, excluding countries with populations less than 1 million.

Example calculation

Below we present an example calculation of SDI for "Country X":

$$TFU25 = 1.09;\ Mean\ educ\ yrs\ pc = 8.23;\ lnLDI = 9.60$$

$$I_{TFU25} = 1 - \frac{1.09 - 0}{3 - 0} = .637$$

$$I_{Educ} = \frac{8.23 - 0}{17 - 0} = .484$$

$$I_{lnLDI} = \frac{9.60 - 5.52}{11.00 - 5.52} = .744$$

$$SDI = \sqrt[3]{I_{TFU25} * I_{Educ} * I_{lnLDI}} = \sqrt[3]{.637 * .484 * .744} = .611$$

$$I_{lnLDI} = \frac{9.58 - 5.52}{11.00 - 5.52} = .741$$

$$SDI = \sqrt[3]{I_{TFR} * I_{Educ} * I_{lnLDI}} = \sqrt[3]{.855 * .543 * .741} = .701$$

SDI grouping by location can be found in Appendix Table 9, and SDI values can be found in Appendix Table 10.

Section 2.11: Epidemiological Transition

Section 2.11.1:Derivation of expected SEVs

In order to evaluate the average relationship between SDI attributable burden, we first quantified that between SDI and population-level exposure. Using the "gam" package in R, we fit a generalized additive model (GAM) with a loess smoother on SDI by age and sex group. For age *a*, sex *s*, and risk *r*.

$$logit(SEV_{asr}) = \beta_0 + s(SDI) + \epsilon$$

Inputs to this model were age-sex specific SEVs for all most-detailed risks in the GBD risk hierarchy corresponding to all national GBD locations and years between 1990 and 2017. The span for the loess term was set at a default of .7, and the model was fit on the middle 95% of the data to mitigate the impact of compositional bias evident in outliers very close to zero or one. Expected age and sex proportions of the population on the basis of SDI produced through an analogous modelling framework were used to generate age and sex aggregates of expected exposure.

Section 2.11.2:Calculating attributable burden

Borrowing from forecasting methods, we generated an estimated expected risk-specific PAF by back-transforming the expected SEV to PAF, rearranging the formula for SEV described in further detail in the appendix to solve to PAF for a given age a, sex s, cause c, risk r, and SDI d,

$$PAF_{ascrd} = 1 - \frac{1}{SEV_{asrd} \times (RR_{ascr}^{max} - 1) + 1}$$

As PAF estimates are derived directly from the SEV which is not cause specific, but averaged across causes, we then calculated a correction factor CF by comparing in logit space the empirical PAF to the SEV derived estimate PAF,

$$CF_{ascr} = logit\left(PAF_{ascrly}\right) - logit(PAF_{ascrly})$$

and apply the correction factor to the estimated expected PAF to derived an adjusted expected estimated PAF

$$PAF_{ascrd} = expit(logit(PAF_{ascrd}) + CF_{ascr})$$

for all most-detailed risks in the hierarchy, excluding unsafe sex and occupational injuries, by age, sex, cause, and SDI, adding in risk-outcome

To estimate expected risk-attributable burden, we draw from the CRA methods (see Appendix Section 2.6), first calculating the joint adjusted expected PAF for all risks for a cause using mediation factors. We then draw from the methods for observed risk-attributable burden calculation, using expected YLLs, deaths, and YLDs (see Appendix Section 2.7) to generate expected burden for a given SDI, not location year.

$$AB_{rascd} = \sum DALY_{ascd} PAF_{rascd}$$

where AB_{rascd} is the expected attributable burden; $DALY_{ascd}$ is expected total; PAF_{ascrd} is the expected PAF. The proportion of expected deaths, YLLs, or YLDs attributable to a given risk factor or risk factor cluster were analogously computed by sequentially substituting each measure in place of expected DALYs in the equation above. Comparisons of observed to expected attributable burden were made to identify locations exhibiting exceptional deviations relative to what would be expected based on their development status.

Section 2.12: Additional Methods Information

Section 2.12.1: Risk-specific comparisons to other estimates

Low birth weight / Short Gestation:

GBD 2017 estimates of total preterm birth prevalence are generally in line with country-specific reports[30] as well as the most recent global analysis completed by Blencowe and colleagues.[31] GBD 2017 estimates of preterm birth prevalence in 2010 are very similar, 11.3% (95% UI: 11.1% to 11.5%) versus 11.1% of live births, compared to estimates by Blencowe and colleagues. Close agreement is not surprising as most of the same data sources were used as data inputs to our modelling process, although the GBD analysis included almost eight times as many data points. Most reports, like GBD 2017, have assessed temporal trends in preterm birth in many locations to be either static or increasing. Compared to UNICEF estimates of low birth weight,[32] GBD 2017 estimates of global birth prevalence of 14.4% (14.0% to 14.8%) are similar but slightly lower than the estimate of 15.5% birth prevalence globally. The geographic variation in low birth weight largely mirrors that of the UNICEF report.

Chewing Tobacco

In GBD 2016, we estimated age-sex specific and aggregate current smokeless tobacco use prevalence for all countries and territories from 1990-2016 using all available data. The estimated prevalence was then

attributed to either all chewing tobacco, or all snus/snuff by country, based on input from smokeless tobacco experts.

For GBD 2017, we have changed the exposure definition from current smokeless tobacco use to current chewing tobacco use, based on the strength of evidence supporting the health effects of chewing tobacco use. By estimating chewing tobacco exposure in all countries and territories, burden is now estimated for locations previously classified as predominantly snus/snuff, but still have non-negligible use of chewing tobacco.

We compared GBD estimates to recent research by Siddiqi et al.[33] on smokeless tobacco prevalence, risk, and burden in 2015. Our methods differed from Siddiqi on some key points:

Prevalence estimation: We estimated both age-sex specific and aggregate current smokeless tobacco use prevalence for all countries and territories included in GBD from 1990-2017 using all available data. Siddiqi et al. used only the single most recent survey available containing data on smokeless tobacco use among adults.

Relative risks and attributable burden: GBD excluded hospital-based case-control studies, while Siddiqi included them. GBD calculated relative risks for chewing tobacco (and by sex for oral cancer only), while Siddiqi calculated separate relative risks by geography, and then pooled these to produce global relative risks. Siddiqi used country- or region-specific relative risks where available, and in the absence of region-specific relative risks assigned global relative risks in countries predominantly using products with moderate to high pH and tobacco-specific nitrosamine (TSNA) levels.

The main differences in attributable burden come from the relative risk exclusion criteria. GBD's exclusion of hospital-based led to very different relative risk outputs: we found significant relative risks for oral cancer and oesophageal cancer. Siddiqi found significant relative risks for oral, pharyngeal, and oesophageal cancers and ischemic heart disease, resulting in higher levels of global burden.

Smoking

We compared GBD estimates to the most recent report on the global tobacco epidemic published by WHO[30]. Overall, we found marked similarities in estimates. Among the 142 countries and territories included in the WHO report and estimated in GBD, the correlation coefficient for current smoking prevalence estimates among females was 0.91 and among males was 0.85. In cases where estimates diverge, discordance can be attributed to differing modelling methods or data sources. GBD uses ST-GPR to estimate smoking prevalence, whereas WHO uses Bayesian meta-regression (DisMod MR). Additionally, the WHO model was fit on 1,175 country-year data sources, whereas the GBD model was fit on 2,870 country-year data sources. There are no comparable global estimates of the burden of disease attributable to smoking, as GBD 2015 estimates of attributable burden were used in the most recent WHO report.

Ambient air pollution

In the past few years, other researchers have estimated the burden of disease due to air pollution using different data and methods. Other sources of estimates have been compared to those of the GBD. Since their introduction in GBD 2010, satellite-based estimates of $PM_{2.5}$ and the Integrated Exposure Response (IER), have been widely adopted. Recent estimates from WHO[31] of 3·0 million deaths in 2012 used a

similar exposure estimate model as that presented here, but an earlier (GBD 2013) version of the integrated exposure response (IER) and somewhat different baseline disease burden estimates. Lelieveld and colleagues[32] analysed source sector contributions to air pollution and the resulting disease burden in 2010 and estimated the burden in 2050. These estimates used an older (GBD 2010) IER. Furthermore, the coarse spatial resolution (~100 × 100 km) of the exposure estimates introduced errors via spatial misalignment between exposure and population density compared with our estimates. Silva et al. estimated 2.23 million deaths/year due to anthropogenic $PM_{2.5}$ and 493 thousand deaths per year due to ozone,[33] while Butt et al. estimated 12.4% global attributable deaths due to $PM_{2.5}$ in the year 2009,[34] both using versions of the IER.

In GBD 2017, we added Type 2 diabetes as an outcome of ambient particulate matter pollution estimating 184 thousand attributable deaths and 10.5 million attributable DALYs globally in the year 2017. An independent group of researchers recently published work estimating the 2016 burden of diabetes attributable to ambient $PM_{2.5}$.[35] Using GBD 2015 $PM_{2.5}$ exposure estimates, GBD 2016 diabetes burden, and generating their own IER the team estimated 206 thousand attributable deaths and 8.23 million attributable DALYs globally for the year 2016.

Occupational

Takala and colleagues[36] reported 2.3 million deaths attributable to occupational injury/illness in 2011. In the closest comparison year of 2007, GBD estimated nearly 1.1 million deaths. This discrepancy is largely driven by the cause-outcome pairs that GBD currently has the evidence to include based on the criteria of the CRA framework. For example, 45% of Takala's reported burden is driven by occupational circulatory disease (35%) and occupational communicable disease (10%). Circulatory diseases are linked to occupational risks like shift work and lack of control, but the GBD approach currently has insufficient evidence to estimate the variability in exposure to these factors on a global scale. Additionally, the use of a CRA approach in GBD estimates requires careful consideration of proposed counterfactual in order to derive the TMREL for a given risk. The TMREL for something like occupational lack of control is a challenging concept, and as such, these risks are still being reviewed for possible inclusion in future iterations of the GBD.

Takala also reports higher burden from occupational cancer based on the inclusion of carcinogens that are currently still out of the scope of GBD. For example, the authors use attributable fractions derived from Rushton and colleagues to attribute pairs like breast cancer and shift work or skin cancer and solar radiation. These carcinogens, which form a large part of the cancer burden in Takala/Rushton are currently not included in the GBD based on limited exposure data across the time/space that GBD estimates[38].

In terms of fatal occupational injuries, Takala reported 353 000 deaths in 2011. The GBD 2017 estimate for deaths attributable to occupation was approximately 348 000 deaths for 2007. The figures are very similar but the GBD estimates are slightly lower, again due to the selection of risk-cause pairs. The ILO estimation strategy includes some kinds of injuries, such as deaths due to intentional violence that the GBD does not attribute to occupation.

Child growth failure (stunting, wasting, and underweight)

UNICEF et al estimate lower proportion of stunting (height-for-age z-score < -2 standard deviations below the reference median) in children under five in 2017 than GBD 2017.[37] The geographic patterns generally agree in identifying sub-Saharan Africa and South Asia as the regions with the largest burden of stunting (prevalence and magnitude, estimated as number of stunted children in UNICEF et al, and as DALYs in GBD 2017), with additional high prevalence in Oceania (excluding Australia and New Zealand) and moderate prevalence in Latin America and the Caribbean. While UNICEF et al estimates highlight minimal or lack of progress in reducing stunting since 2000 in Africa and Oceania, GBD 2017 estimates show moderate decline in sub-Saharan Africa and North Africa and the Middle East, and a small decline in Oceania (compared to UNICEF et al's rise in stunting prevalence in Oceania). GBD 2017 estimates show a downward trend in the prevalence of underweight (weight-for-age z-score < -2 standard deviations below the reference median) among children under 5 in 2016, driven largely by populations in sub-Saharan Africa and South Asia, a trend also reflected in the UNICEF et al estimates.

Impaired Kidney Function

Recently published estimates from a meta-analysis of global data on exposure to impaired kidney function indicate prevalence of chronic kidney disease (CKD) stages 1-5 to be 13.4% (11.7-15.1%). (ref) These estimates are similar to the current GBD 2017 exposure estimates across all four levels of impaired kidney function, which indicate a prevalence for individuals over the age of 25 of 14.0% (13.0-15.1%).

Household Air Pollution

WHO estimated 4.3 million deaths and 146.5 million DALYs attributable to exposure to household air pollution globally in 2012, as compared to GBD 2017 estimates for the year 2017 of 1.6 million deaths and 59 million DALYs. Differences in attributable burden arise between the WHO estimates and GBD 2016 for a number of reasons. First, the IER curve was used for all outcomes (LRI, IHD, cerebrovascular stroke, COPD, Type II Diabetes, and lung cancer) except cataracts in our analysis, while WHO adapted relative risks for COPD based on a meta-analysis of published RR estimates. The excess relative risks for COPD used by WHO are larger than the excess relative risks used in GBD, resulting in a larger PAF. Additionally, this was the first year we included Type II Diabetes as an outcome of particulate matter pollution, including household exposure to solid fuel. WHO has not included this as an outcome in their estimates. Finally, WHO only estimates LRI deaths in children aged 0-4, while we estimate respiratory infections and pneumonia at all ages.

Additionally, by adapting the new proportional PAF approach for particulate matter pollution, beginning in GBD 2017 we are taking into account ambient pollution in the counterfactual of household. This has reduced burden estimates from previously published numbers, which we believe more accurately reflects the exposure-outcome relationship.

Another difference from the WHO estimates is the use of a database which maps solid cooking fuel use to $PM_{2.5}$ exposure, allowing us to model differences in exposure level and relative risk by location, while WHO relies on global relative risks. We also adjust this household $PM_{2.5}$ exposure by ambient air pollution levels since personal $PM_{2.5}$ exposure captures all sources of exposure. WHO makes no

adjustments for ambient air pollution exposure. In addition to the differences in data sources, we estimated the burden of cataract attributable to household air pollution (HAP) only in women while WHO estimated for both sexes.

Below is a comparison between the WHO[38] and GBD 2017 of the number of DALYs attributed to HAP contributed by each cause (GBD 2017 on right):

- 48,500,000-Pneumonia/LRI — 25,400,000-Lower respiratory infections
- 36,900,000-Stroke — 8,010,000-stroke
- 30,500,000-Ischaemic heart disease — 9,170,000-IHD
- 22,100,000-COPD — 11,700,000-COPD
- 6,720,000-Lung cancer — 1,780,000-Lung cancer
- 1,670,000-Cataract — 1,230,000-Cataract
- 0-Type 2 diabetes — 830,000-Type 2 diabetes

Breastfeeding

Globally, WHO estimates that 40% of infants under six months of age are exclusively breastfed, which is consistent with the GBD 2017 estimate (40.3%). A recent WHO study estimates 73.3% continued breastfeeding at one year of age globally, where the GBD 2017 estimate of continued breastfeeding between 6 and 11 months is 88% (we expect our estimates to be higher, as our estimates measure breastfeeding for any infants age 6-11 months, while the WHO estimates focus on breastfeeding status at the age of 1 year).[39] CDC reports 25% of mothers in the United States exclusively breastfeed their child through 6 months of age, while GBD 2017 estimates that 42% of infants 0-5 months are exclusively breastfed (this difference is again explained by our estimates focusing on all infants 0-5 months, while the CDC reports infants who complete 6 full months of exclusive breastfeeding). Additionally, CDC reports 34% of mothers in the U.S. continue to breastfeed at 12 months of age. GBD estimates 44% of mothers in the U.S. continue to breastfeed from 6 to 11 months of age. Finally, in India, WHO and UNICEF estimate 55% exclusive breastfeeding in the first six months of life, comparable to the GBD 2017 estimate of 55%.

WaSH

The Joint Monitoring Project[40] (JMP), which is led by WHO and UNICEF, estimates water, sanitation, and handwashing access throughout the world. Globally, JMP estimates that 91% of population had access to an improved water source in 2015, while GBD estimates 88% of the population have access to improved water. Additionally, JMP reported the global prevalence of households with piped water connection to be 57% in 2015, while GBD reports piped prevalence of 53% for that year. JMP reported 68% of population had access to improved sanitation in 2015, whereas GBD estimates improved sanitation prevalence of 74%. The slight discrepancies in these estimates at the global level can be largely attributed to differences in input data. The JMP relies almost exclusively on large-scale household surveys (DHS and Multiple Indicator Cluster Surveys [MICS]), while GBD estimates incorporate exposure data from smaller, yet still nationally representative, survey series such as Reproductive Health Survey and various country specific surveys. Due to the relative dearth of data regarding access to a handwashing facility, the JMP only generates handwashing estimates for a select

number of countries (mostly sub-Saharan Africa) where those data are actually collected. However, we model and predict handwashing facility prevalence for all locations, even in the absence of data, and estimates that 67% of the globe has access to a handwashing facility.

Lead

The most recent external estimates for the burden of lead exposure were conducted by WHO in 2004 and provided disaggregated average exposures for children and adults in different regions of the world.[41] The GBD 2017 exposure estimates for the early 2000s are generally higher than these estimates, as we have observed higher estimates of exposure in GBD 2017 with changes in model covariates and covariate effects. The WHO study calculated a global burden attributable to lead exposure of 13 million DALYs, which includes 229 000 deaths. GBD 2017 estimates global burden attributable to lead exposure to be 24.4 million DALYs, including approximately 1.05 million deaths.

In addition to differences in overall attributable burden, the breakdown of burden from intellectual disability and cardiovascular disease is very different. Both attribute 2% to 3% of global CVD to lead exposure, but our estimates of CVD burden in 2007 are higher than WHO's (such that we estimate 18.1 million DALYs from CVD due to lead in 2007 compared to their estimate of 3.1 million). Additionally, our methodology for intellectual disability differs substantially from theirs. In the WHO study, they used a higher disability weight of 0.361 for intellectual disability, whereas we currently use weights ranging from 0.01 to 0.2 (depending on the severity). However, WHO's estimates of intelligence quotient (IQ) shift from lead exposure are much lower than ours, since recent studies have provided better evidence for notable effects of lead on IQ at low levels of exposure. Still, due to differences in our estimates of the underlying burden of intellectual disability, our estimate of 2.67 million DALYs from intellectual disability attributable to lead exposure in 2007 is much smaller than their estimate of 9.8 million.

Intimate partner violence

WHO reports a global lifetime prevalence of physical and/or sexual intimate partner violence among ever-partnered women of 30.0% (27.8-32.2).(ref) For GBD 2017, the estimated all-age global exposure for intimate partner violence (IPV) in 2017 is 19.7% (16.1-24.3) among all women, which is a smaller estimate than the WHO estimate because WHO estimates are among only ever-partnered women, while the estimates used for GBD risk factor exposure are among all women. After making an adjustment using our model for the proportion of women who have ever been partnered, we estimate global lifetime IPV exposure as 32.5% (25.9-40.9) among ever-partnered women – an estimate that agrees with the WHO report. The regional distribution reported by WHO is in agreement with the distribution by GBD super-region; highest prevalence of IPV in North Africa and Middle East; South Asia; and sub-Saharan Africa and lower prevalence in Southeast Asia, East Asia, and Oceania; Central Europe, Eastern Europe, and Central Asia; high-income; and Latin American and Caribbean.

Iron deficiency

Iron deficiency (ID) was the fourth ranked level 3 risk factor in 1990, decreasing to sixth in 2017 after increasing 15.23% over that time period in terms of attributable YLDs, almost all of which was YLDs due to dietary iron deficiency (IDA). We have not identified any other global, systematic analyses of ID as a risk factor for increased disease burden so we are not able to compare our estimates of ID-attributable health loss. There are a number of other studies that have evaluated the prevalence of ID and IDA, however.[42] The most comprehensive meta-analysis from Low and Middle-Income Countries (LMIC) estimated a much lower prevalence of ID/IDA than we have for GBD 2017. There are three aspects that

make a direct comparison with GBD 2017 difficult. First, the study by Petry and colleagues likely underestimated ID/IDA somewhat by applying a single cut-off for diagnosing ID of <12 grams per decilitre of plasma ferritin concentration, especially with the acknowledged limitation of not being able to fully account for the effect of inflammation in many of its component studies. Second, Petry and colleagues did not distinguish aetiologies of ID/IDA whereas GBD does distinguish many causes of anaemia (e.g. hookworm, gastritis) that can manifest as ID. Third, whereas Petry and colleagues made direct estimation of ID/IDA from serum measurements, the GBD approach for estimating ID/IDA is indirect and therefore does not have a directly comparable case definition. We began by first estimating overall anaemia then, after reassigning large portions to >25 other underlying causes, used fixed proportion redistribution methods to estimate IDA. The risk exposure for ID was then estimated as a counterfactual haemoglobin concentration in the absence of all the "other" causes rather than an explicit prevalence value. Unless all possible causes of anaemia are included, the GBD approach has potential to overestimate the proportion of anaemia to be redistributed to ID/IDA in places where other causes are important. We have begun work to address this in GBD 2017 by adding Cirrhosis, Crohn's Disease, Ulcerative Colitis, and others as causes of anaemia, but there are still a number of others (e.g. cancers, alpha thalassemia, intestinal infections, and other nutritional deficiencies) that have yet to be included.

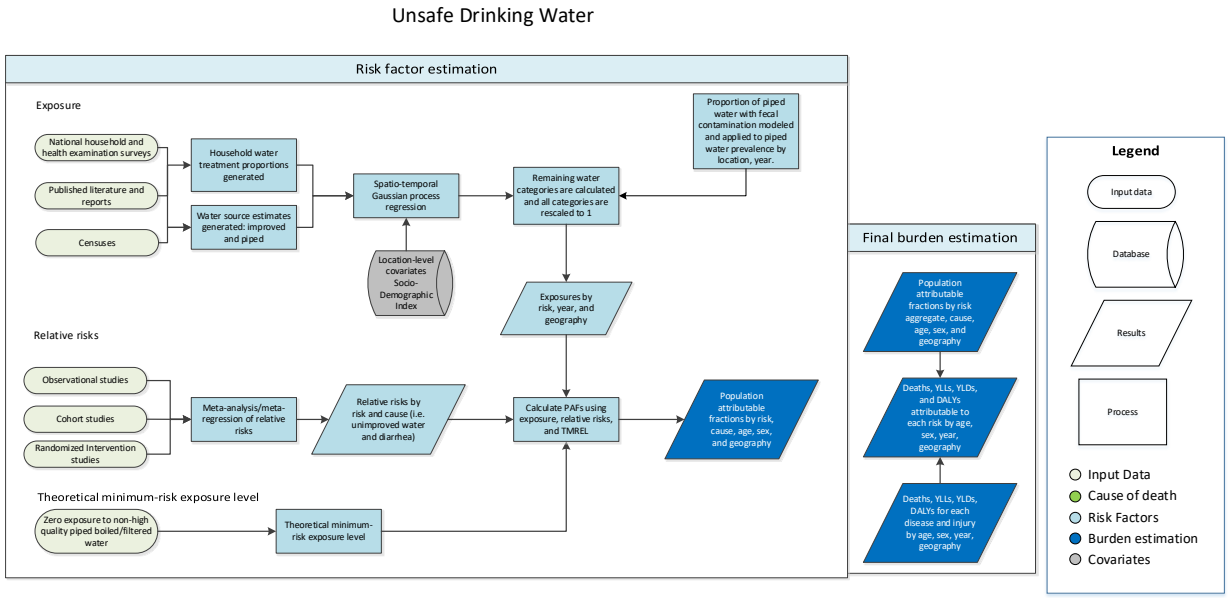
Section 4: Risk-specific estimation

The risk-specific modelling write-ups follow the order of the risk factor hierarchy for GBD 2017. In some cases, multiple risk factors are addressed in a single write-up, for example child underweight, wasting, and stunting are all included in a single detailed write-up.

Unsafe Water Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

For GBD 2017, exposure to unsafe water was defined based on reported primary water source used by the household and use of household water treatment (HWT) to improve the quality of drinking water before consumption. Water sources were defined as "improved" based on the JMP designation,[1] which includes piped water as improved water, and households with access to piped water connection to the house, yard, or plot were defined as having access to piped water supply. Solar treatment, chlorine treatment, boiling, or the use of filters were all established as effective point-of-use household water treatments based on effect sizes calculated from network meta-analysis.

Input data

The search for usable household surveys and censuses was conducted using the Global Health Data Exchange (GHDx) database. HWT input data is primarily limited to two large survey series (DHS and MICS) due to data availability. Water source data includes censuses and nationally representative surveys such as DHS, MICS, AIS, and WHS. For each survey, household sample weights were multiplied by the number of household members to produce a weighting scheme that estimates proportion of individuals, not proportion of households, exposed to a given indicator. Surveys and censuses were then tabulated to the two water source and two water treatment categories of interest for each location.

Modelling

Water source data is modelled using an ordinal framework, with two distinct models: prevalence of piped water and proportion of improved water (excluding piped) within the non-piped population. Both models produce results for each unique location, year combination. This ordinal framework allows us to estimate the category with the most data (piped water prevalence) and leverage that estimate to

anchor the estimates for improved and unimproved water categories. The results of the improved proportion model are multiplied by the piped water prevalence to calculate improved water prevalence. The sum of improved and piped water prevalence are subtracted from 1 to yield unimproved water prevalence.

HWT categories are estimated in a similar ordinal framework, by modelling prevalence of individuals using no water treatment methods and proportions of households that boil/filter water within the population of households that engage in treatment methods. The prevalence of individuals that boil/filter drinking water is calculated by multiplying the proportion that boil/filter modelled previously times prevalence of any water treatment (estimated by subtracting prevalence of no treatment from 1). The prevalence of individuals that treat their water using solar/chlorine methods was estimated by subtracting the sum of prevalence of no treatment estimates and prevalence of filter/boil treatment from 1. By year and location, each of the above categories are modelled using a 3-step modelling scheme of mixed effect linear regression followed by spatio-temporal Gaussian process regression (ST-GPR), which produces full time series estimates for each GBD 2017 location. Socio-demographic index (SDI), a composite metric combining education per capita, income per capita, and fertility, was set as a fixed effect in the linear regression since it proved to be a significant predictor. Random effects were set at GBD 2017 region and super-region levels to fit the models but were not used in the predictions.

The process of vetting and validating models was accomplished primarily through an examination of ST-GPR scatter plots by GBD 2017 location from 1990-2017. Any unfitting data points were re-inspected for error at the level of extraction and survey implementation, and subsequently excluded from analysis if deemed appropriate. In addition to SDI, a number of different potential fixed effects were considered, including lag-distributed income and urbanicity, but SDI proved to be the strongest predictor of the unsafe water categories. Uncertainty in the estimates was initially formed based on standard deviation by survey, then propagated through ST-GPR modelling by means of confidence intervals around each data point that reflect the point-estimate specific variance.

Once models are vetted, full time series outputs from ST-GPR modelling are then converted from proportion to prevalence by year and geography and then rescaled to form 9 mutually exclusive categories that sum up to 1. The table below provides the final result of this rescaling.

Category	Definition
Unimproved, no HWT	Proportion of individuals that primarily use unimproved source, and *do not* use any HWT to purify their drinking water.
Unimproved, chlorine/solar	Proportion of individuals that primarily use unimproved source, and solar or chlorine treatment to purify their drinking water.
Unimproved, boil/filter	Proportion of individuals that primarily use unimproved source, and boil or filter to purify their drinking water.
Improved water except piped, no HWT	Proportion of individuals that primarily use improved sources other than piped water supply, and *do not* use any HWT to purify their drinking water.

Improved water except piped, chlorine/solar	Proportion of individuals that primarily use improved sources other than piped water supply, and use solar or chlorine treatment to purify their drinking water.
Improved water except piped, boil/filter	Proportion of individuals that primarily use improved sources other than piped water supply, and boil/filter their drinking water.
Basic piped water, no HWT	Proportion of individuals that primarily use basic piped water supply, and *do not* use any HWT to purify their drinking water
Basic piped water, chlorine/solar	Proportion of individuals that primarily use basic piped water supply, and *use* solar or chlorine water treatment to purify their drinking water.
Basic piped water, boil/filter	Proportion of individuals that primarily use basic piped water supply, and boil or filter to purify their drinking water
High-quality (HQ) piped water, boil/filter	Proportion of individuals that primarily use basic piped water supply, and boil or filter to purify their drinking water

We modelled the microbiological quality of piped water sources primarily using data a review by Bain et al.[1] that measured proportion of piped water sources contaminated with fecal indicators. We use the value generated from this model to split the prevalence of piped water into basic piped water and high quality piped water by location, year, age, and sex.

A substantial limitation in our analysis is the paucity of data on HWT and piped water quality. The inclusion of more location-specific data on water treatment utilisation at the household level can greatly improve our estimates in future iterations.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for unsafe water is defined as all households have access to high quality piped water that has been boiled or filtered before drinking.

Relative risks

For GBD 2017, unsafe water was paired with one outcome-diarrheal diseases-given evidence provided by relative risk studies. A meta-analysis by Wolf et al.[3] provided the bulk of the relative risk evidence for the relationship between unsafe water and diarrheal diseases. This meta-analysis was updated through a literature review that searched for related intervention studies post-2014 conducted in PubMed. Search terms used were identical to those provided by Wolf et al.[3] Relative risk values for water-source interventions and point-of-use treatment interventions were calculated using network meta-analysis approach so as to include studies that differ in control groups within the same analysis. This analysis produced distinct relative risks for each water source and water treatment category. The combined effect of a source intervention and point-of-use intervention was assumed to be multiplicative in order to match GBD 2017 exposure definitions. Please refer to appendix tables for more information on relative risk values and citations.

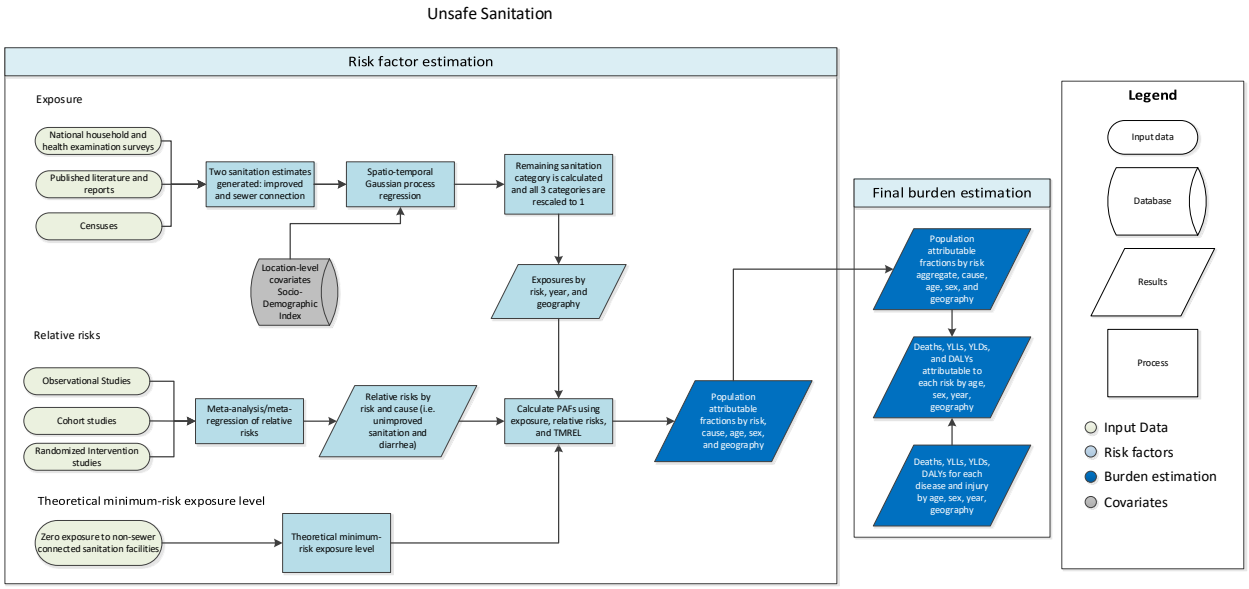
Unsafe Sanitation Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Exposure to unsafe sanitation is defined based on the primary toilet type used by households. Improved facilities are defined as such based on JMP designation (WHO). Sewer connection toilets included flush toilets or any toilet with connection to the sewer or septic tank.

Input data

The search for usable household surveys and censuses was conducted using the Global Health Data Exchange (GHDx) database. For each survey, household sample weights were multiplied by the number of household members to produce a weighting scheme that estimates proportion of individuals, not proportion of households, exposed to a given indicator. Surveys and censuses were then tabulated to two sanitation categories, sewer connection and improved sanitation, for each location. Data in tabulated form was lower priority to add to models and was only updated when time permitted.

Modeling

A change made for GBD 2017 was to model sanitation categories in an ordinal framework instead of independent models. Two distinct indicators were estimated: the prevalence of individuals using sewer connection or septic tank facilities and the proportion of individuals with improved sanitation within the population not connected to sewer or septic tank. This ordinal framework allows us to estimate the category with the most data (sewer connection/septic tank prevalence) and leverage that estimate to anchor the estimates for improved and unimproved sanitation categories. The results of the improved proportion model are multiplied by the sewer connection/septic tank prevalence to calculate improved sanitation prevalence. The sum of improved and sewer connection/septic tank prevalence are subtracted from 1 to yield unimproved sanitation prevalence.

The two indicators were modeled using a 3-step modeling scheme of mixed effect linear regression followed by spatio-temporal Gaussian process regression (ST-GPR), which produced full time series estimates for each GBD 2017 location. Socio-demographic index (SDI), a composite metric combining education per capita, income per capita, and fertility, was set as a fixed effect in the linear regression since it proved to be a significant predictor. Random effects were set at GBD 2017 region and super-region levels to fit the models but were not used in the predictions.

The process of vetting and validating models was accomplished primarily through an examination of ST-GPR scatter plots by GBD 2017 location from 1990-2017. Any unfitting data points were re-inspected for error at the level of extraction and survey implementation, and subsequently excluded from analysis if deemed appropriate. In addition to SDI, a number of different potential fixed effects were considered, including lag-distributed income and urbanicity, but SDI proved to be the strongest predictor of unsafe sanitation in terms of magnitude of the coefficient. Uncertainty in the estimates was initially constructed based on standard deviation around each survey mean, then propagated through ST-GPR modeling by incorporating the variance of each data point in the Gaussian process regression step. A data point with high variance, for example, would contribute relatively less influence to the model than a data point with lower variance.

Once models are vetted, full time series outputs from ST-GPR modeling are then converted from proportion to prevalence by year and geography and then rescaled to form three mutually exclusive categories that sum up to 1. The table below provides the final result of this rescaling.

Category	*Definition*
Unimproved sanitation	Proportion of individuals that use unimproved sanitation facilities.
Improved sanitation	Proportion of individuals with access to improved sanitation facilities, excluding sewer connection or septic tank.
Sanitation facilities with sewer connection or septic tank	Proportion of individuals with access to toilet facilities with sewer connection or septic tank.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for unsafe sanitation was defined as all individuals have access to a sanitation facility with sewer connection.

Relative risks

For GBD 2017, unsafe sanitation was only paired with one outcome, diarrheal diseases. A meta-analysis by Wolf et al. 2014 provides the bulk of the relative risk evidence for the relationship between unsafe sanitation and diarrheal diseases. This meta-analysis was updated through a literature review that searched for related intervention studies post-2014 conducted in PubMed. Search terms used were identical to those provided by Wolf et al. 2014. Please refer to appendix tables for more information on relative risk values and citations.

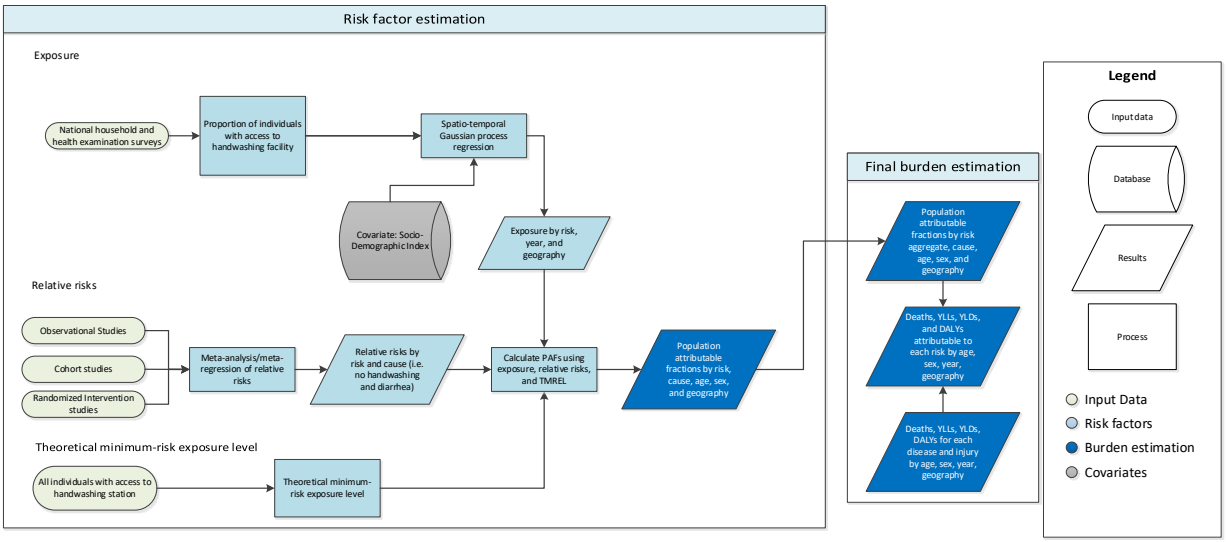
Unsafe Hygiene Capstone Appendix

Flowchart

Unsafe Handwashing



Input data & methodological summary

Exposure

Case definition

Unsafe hygiene is defined as lack of access to a handwashing station with available soap and water. We estimated the burden of unsafe hygiene in both developed and developing settings.

Input data

Since water and soap availability data are very limited, only country-specific Demographic Health Surveys (DHS) and Malaria Indicator Survey Series (MICS) conducted after 2006 were included as input data.

Modelling strategy

By year and location, proportion of households with handwashing facility is modelled using a 3-step modelling scheme of mixed effect linear regression followed by spatio-temporal Gaussian process regression (ST-GPR), which outputs full time series estimates for each GBD 2017 location. Socio-demographic index (SDI), a composite index that include income per capita, education, and fertility, was set as a fixed effect in the linear regression since it proved to have significant coefficient. Random effects were set at GBD 2017 region and super-region levels to fit the model but were not used in the predictions.

The process of vetting and validating models was accomplished primarily through an examination of ST-GPR scatter plots by GBD 2016 location from 1990-2016. Any data points lacking face validity were re-inspected for error at the level of extraction and survey implementation, and subsequently excluded from analysis if deemed appropriate. In addition to SDI, a number of different potential fixed effects

were considered, including lag-distributed income and urbanicity. However, SDI proved to be the strongest predictor.

A considerable limitation for when estimating handwashing practices for over 190 independent locations around the world was data sparseness. Even when data were published on handwashing prevalence, the definition was often altered from the GBD 2017 standard definition or it may only have pertained to certain populations (such as hospital patients) and lacked representativeness at the geographic scale we required. The incorporation of questions about soap and water availability in DHS and MICS added much-needed information but there remains a large data gap to be filled if we are to become more certain in handwashing access estimates.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for unsafe hygiene is defined as all individuals with access to handwashing facility after any contact with excreta, including children's excreta.

Relative risks

A meta-analysis by Cairncross et al.[1] provide relative risk values describing the relationship between lack of facility access and diarrheal diseases. A meta-analysis by Rabie and Curtis[2] provided relative risk evidence for the relationship between lack of facility access and lower respiratory infection. Please refer to appendix tables for more information on relative risk values and citations.

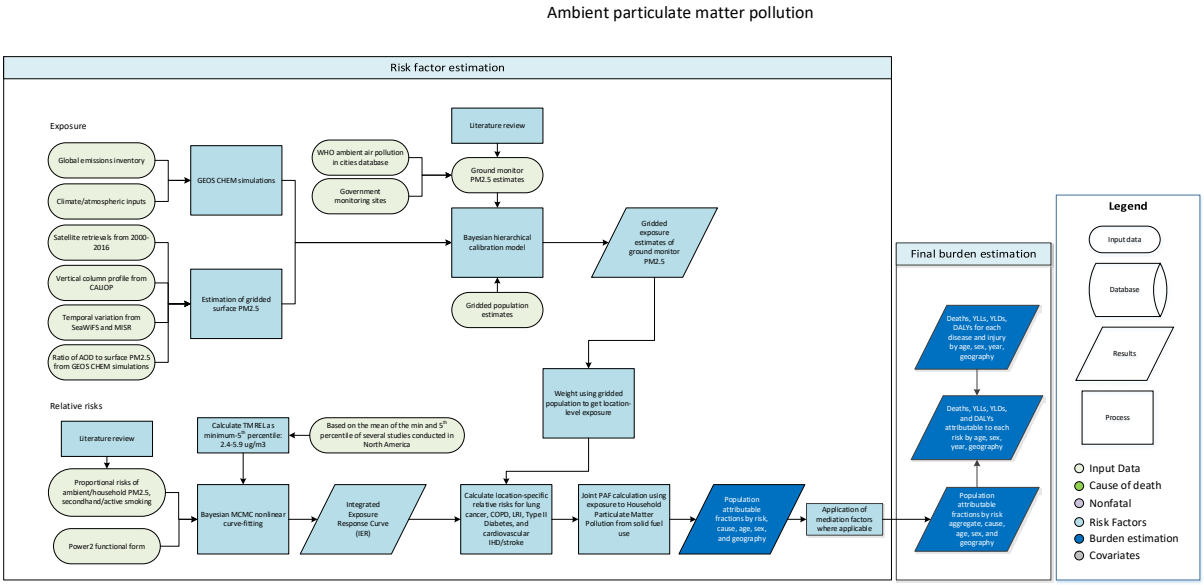
Ambient Particulate Matter Pollution Capstone Appendix

Flowchart



Input data and modeling strategy

Exposure

Definition

Exposure to ambient air pollution is defined as the population-weighted annual average mass concentration of particles with an aerodynamic diameter less than 2.5 micrometers ($PM_{2.5}$) in a cubic meter of air. This measurement is reported in $\mu g/m^3$.

Input Data

The data used to estimate exposure to ambient air pollution is drawn from multiple sources, including satellite observations of aerosols in the atmosphere, ground measurements, chemical transport model simulations, population estimates, and land-use data.

The following details the updates in methodology and input data used in GBD 2017.

$PM_{2.5}$ ground measurement database

Updates of ground measurements used for GBD 2017 include using more recent data than that used previously and the addition of data from new locations. The data from the 2018 update of the WHO Global Ambient Air Quality Database include monitor-specific measurements of concentrations of PM_{10} and $PM_{2.5}$ from 9,960 ground monitors (up from 6,003 in GBD 2016) from 108 countries. The majority of measurements were recorded in 2016 (as there is a lag in reporting measurements, little data from 2017 were available). Annual averages were excluded if they were based on less than 75% coverage within a year. Collection year ranged from 2008 to 2017 in data used. If information on coverage was not available then data were included unless they were already sufficient data within a country (monitor density greater than 0.1).

For locations measuring only PM_{10}, $PM_{2.5}$ measurements were estimated from PM_{10}. This was performed using a hierarchy of conversion factors ($PM_{2.5}/PM_{10}$ ratios): (i) for any location a 'local'

conversation factor was used, constructed as the ratio of the average measurements (of $PM_{2.5}$ and PM_{10}) from within 50km and within the same country, if such were available' (ii) if there was not sufficient local information to construct a conversion factor then a country-wide conversion factor was used; and (iii) if there was no appropriate information within a country then a regional factor was used. In each case, to avoid the possible effects of outliers in the measured data (both $PM_{2.5}$ and PM_{10}), extreme values of the ratios were excluded (defined as being greater/lesser than the 95 and 5% quantiles of the empirical distributions of conversion factors) of the latter two cases for the country measurements were available, for both metrics. As in the GBD 2013 and GBD 2015/GBD 2016 databases, in addition to values of $PM_{2.5}$ and whether they were direct measurement or converted from PM_{10}, the database also included additional information, where available, related to the ground measurements such as monitor geo coordinates and monitor site type.

Satellite-based estimates

The updated satellite-based estimates for years 1998-2016 are described in detail in van Donkelaar et al. 2016.[1] These estimates were available at 0.1°×0.1° resolution (~11 x 11 km resolution at the equator) and combine aerosol optical depth retrievals from multiple satellites with the GEOS Chem chemical transport model and land use information.

Population data

A comprehensive set of population data on a high-resolution grid was obtained from the Gridded Population of the World (GPW) database. These estimates are adjusted to match UN2015 Population Prosepectus. These data are provided on a 0.0417°×0.0417° resolution. Aggregation to each 0.1°×0.1° grid cell comprised of summing the central 3 × 3 population cells. As this resulted in a resolution higher than necessary, it was repeated four times, each offset by one cell in a North, South, East and West direction. The average of the resulting five quantities was used as the estimated population for each grid cell. Population estimates for 2000, 2005, 2010, 2015 and 2020 were available from GPW version 4 revision 10. Populations for 2016 and 2017 were obtained by interpolation using natural splines with knots placed at 2000, 2005, 2010, 2015 and 2020. This was performed for each grid cell.

Chemical transport model simulations

Estimates of the sum of particulate sulfate, nitrate, ammonium and organic carbon and the compositional concentrations of mineral dust simulated using the GEOS Chem chemical transport model, and a measure combining elevation and the distance to the nearest urban land surface (as described in van Donkelaar et al. 2016[1]) were available for 2000 to 2016 for each 0.1°×0.1° grid cell. These were not included within the GBD 2013 analysis.

Modelling strategy

Significant advances have been made in the methodology used to estimate exposure to ambient particulate matter pollution since GBD 2013. The following is a summary of the modelling approach, known as the Data Integration Model for Air Quality (DIMAQ) used in GBD 2015, 2016, and 2017; further details can be found in Shaddick *et al.* (2017). [2]

In GBD 2010 and GBD 2013 exposure estimates were obtained using a single global function to calibrate available ground measurements to a 'fused' estimate of $PM_{2.5}$; the mean of satellite-based estimates and those from the TM5 chemical transport model, calculated for each 0.1°×0.1° grid cell. This was recognised to represent a trade-off between accuracy and computationally efficiency when utilising all the available data sources. In particular, the GBD 2013 exposure estimates were known

to underestimate ground measurements in specific locations (see discussion in Brauer et al., 2013[3]). This underestimation was largely due to the use of a single, global, calibration function, whereas in reality the relationship between ground measurements and other variables will vary spatially.

In GBD 2015 and GBD 2016, coefficients in the calibration model were estimated for each country. Where data were insufficient within a country, information can be `borrowed' from a higher aggregation (region) and if enough information is still not available from an even higher level (super-region). Individual country level estimates were therefore based on a combination of information from the country, its region and super-region. This was implemented within a Bayesian Hierarchical modelling (BHM) framework. BHMs provide an extremely useful and flexible framework in which to model complex relationships and dependencies in data. Uncertainty can also be propagated through the model allowing uncertainty arising from different components, both data sources and models, to be incorporated within estimates of uncertainty associated with the final estimates. The results of the modelling comprise a posterior distribution for each grid cell, rather than just a single point estimate, allowing a variety of summaries to be calculated. The primary outputs here are the median and 95% credible intervals for each grid cell. Based on the availability of ground measurement data, modelling and evaluation was focused on the year 2016.

The GBD 2017 model was updated to also include within country calibration variation.[4] The model used for GBD2017, henceforth referred to as DIMAQ2, provides a number of substantial improvements over the initial formulation of DIMAQ. In DIMAQ, ground measurements from different years were all assumed to have been made in the primary year of interest (i.e. 2014 for GBD2015 before extrapolation) and then regressed against values from other inputs (e.g. satellites etc.) made in that year. In the presence of changes over time therefore, and particularly in areas where no recent measurements were available, there was the possibility of mismatches between the ground measurements and other variables. In DIMAQ2, ground measurements and matched with other inputs (over time) and the possibility of the (global level) coefficients being allowed to vary over time, subject to smoothing that is induced by a second-order random walk process. In addition, the manner in which spatial variation can be incorporated within the model has developed: where there is sufficient data, the calibration equations can now vary (smoothly) both within and between countries, achieved by allowing the coefficients to follow (smooth) Gaussian processes. Where there is insufficient data within a country, to produce accurate equations, as before information is borrowed from lower down the hierarchy and it is supplemented with information from the wider region.

DIMAQ2 is used for all regions except for the North Africa-Middle East and Sub-Saharan super-regions and remote islands where there is insufficient data to allow the extra complexities of the new model to be implemented. In the North Africa-Middle East and Sub-Saharan super-regions a simplified version of DIMAQ2 is used in which the temporal component is dropped, and for remote islands the original DIMAQ is used.

Due to both the complexity of the models and the size of the data, notably the number of spatial predictions that are required, recently developed techniques that perform 'approximate' Bayesian inference based on integrated nested Laplace approximations (INLA) were used.[5] Computation was performed using the R interface to the INLA computational engine (R-INLA). Fitting the models and performing predictions for each of the ca. 1.4 million grid cells required the use of a high performance computing cluster (HPC) making use of high memory nodes.

Model evaluation

Model development and comparison was performed using within- and out-of-sample assessment. In the evaluation, cross validation was performed using 25 combinations of training (80%) and validation (20%) datasets. Validation sets were obtained by taking a stratified random sample, using sampling probabilities based on the cross-tabulation of $PM_{2.5}$ categories (0-24.9, 25-49.9, 50-74.9, 75-99.9, 100+ $\mu g/m^3$) and super-regions, resulting in them having the same distribution of $PM_{2.5}$ concentrations and super-regions as the overall set of sites. The following metrics were calculated for each training/evaluation set combination: for model fit - R^2 and deviance information criteria (DIC, a measure of model fit for Bayesian models); for predictive accuracy - root mean squared error (RMSE) and population weighted root mean squared error (PwRMSE).

All modelling was performed on the log-scale. The choice of which variables were included in the model was made based on their contribution to model fit and predictive ability. The following is a list variables and model structures that were included in DIMAQ.

Continuous explanatory variables:

- (SAT) Estimate of $PM_{2.5}$ (in μgm^{-3}) from satellite remote sensing on the log-scale.
- (POP) Estimate of population for the same year as SAT on the log-scale.
- (SNAOC) Estimate of the sum of sulfate, nitrate, ammonium and organic carbon simulated using the GEOS Chem chemical transport model.
- (DST) Estimate of compositional concentrations of mineral dust simulated using the GEOS Chem chemical transport model.
- (EDxDU) The log of the elevation difference between the elevation at the ground measurement location and the mean elevation within the GEOS Chem simulation grid cell multiplied by the inverse distance to the nearest urban land surface.

Discrete explanatory variables:

- (LOC) Binary variable indicating whether exact location of ground measurement is known.
- (TYPE) Binary variable indicating whether exact type of ground monitor is known.
- (CONV) Binary variable indicating whether ground measurement is $PM_{2.5}$ or converted from PM_{10}.

Random Effects:

- Grid cell random effects on the intercept to allow for multiple ground monitors in a grid cell.
- Country-region-super-region hierarchical random effects for the intercept.
- Country-region-super-region hierarchical random effects for the coefficient associated with SAT .
- Country-region-super-region hierarchical random effects for the coefficient associated with the difference between estimates from CTM and SAT.
- Country-region-super-region hierarchical random effects for the coefficient associated with POP.
- Country level random effects for population uses a neighbourhood structure allowing specific borrowing of information from neighbouring countries.
- Within a region, country level effects of SAT and the difference between SAT AND CTM are assumed to be independent and identically distributed.
- Within a super-region, region level random effects are assumed to be independent and identically distributed.

- Super-region random effects are assumed to be independent and identically distributed.

Interactions*:*

- Interactions between the binary variables and the effects of SAT and CTM.

In addition, DIMAQ2 includes

- Smoothed, spatially varying, random-effects for the intercept
- Smoothed, spatially varying, random-effects for the coefficient of coefficient associated with SAT
- Smoothed, temporally varying, random-effect for the intercept

Results

The final model contained the following variables: SAT, POP, SNAOC, DST, EDxDU, LOC, TYPE, and CONV, together with interactions between SAT and each of LOC, TYPE and CONV. The model structure contained grid cell random effects on the intercept to allow for multiple ground monitors in a grid cell, country-region-super-region hierarchical random effects for intercepts and SAT and country level random effects for population using a neighbourhood structure allowing specific borrowing of information from neighbouring countries together with region-super-region hierarchical random effects for POP. Notably, and as in GBD 2015 and GBD 2016, based on the evaluation of candidate models, including estimates from the TM5 chemical transport model (CTM) used in GBD 2013 did not improve the predictive ability of the model and was therefore not included.

Compared to the model used in GBD2013, DIMAQ showed improved predictions of ground measurements in all super regions with improvements in both within-sample fit; with a global population-weighted RMSE of 12.1 $\mu g/m^3$ compared to 23.1 $\mu g/m^3$ when using the GBD 2013 approach.[1] Using the larger database available for GBD2017, with potentially more variability in measurements, DIMAQ2 shows an additional improvement on DIMAQ: overall population-weighted RMSE reduced from 9.32 to 8.11 (12.12 to 11.17 when using all data, irrespective of within-year coverage). Reductions by super-region can be seen in Figure 1. Reductions can be seen in all super-regions with particular improvement in the Southeast Asia, East Asia and Oceania super-region which is based largely on a substantial increase in accuracy in China, PwRMSE 6 vs 9 $\mu g/m^3$

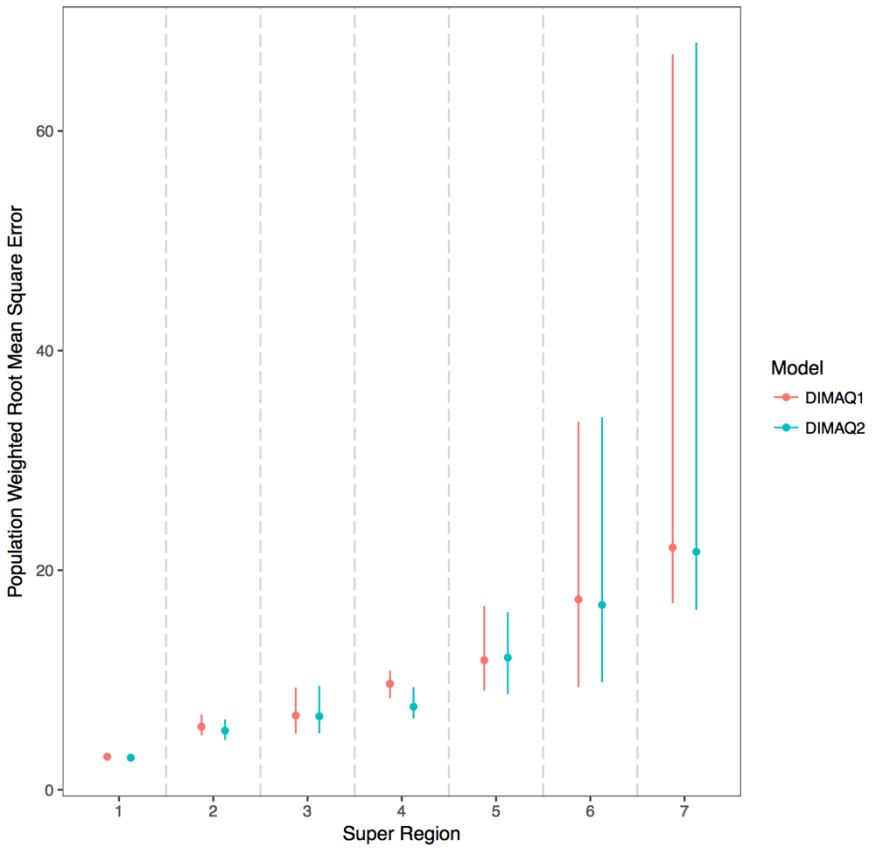


Figure 1: Summary measures of predictive ability, globally and by super-region. Dots denote the median values of population weighted root mean squared error (μg/m³) from 25 validation sets with vertical lines showing the range of values over those sets.

Estimates for other years

In contrast to the method used previously, where estimates (of $PM_{2.5}$) were extrapolated to produce estimates for the year of interest (e.g. 2017 where data was available up to and including 2016) due to the extra complexity of the smooth spatial processes in DIMAQ2 this would not be possible in any straightforward manner. With DIMAQ2 it is the input variables that are extrapolated; this allows estimates for 2017 to be produced in the same way as other years and crucially, allows measures of uncertainty to be produced within the BHM framework rather than by using post-hoc approximations.

Satellite estimates and quantities estimated using the GEOS-Chem model were available for 1990, 1995, 2000, 2005, 2010-2016. Estimates of these input variables for 2017 were produced by extrapolating, on a cell-by-cell basis, using natural splines. Population estimates for 2000, 2005, 2010, 2015 and 2020 were availalble from GPW version 4. For 1990 and 1995 data were extracted from GPW version 3, as in GBD2013.[2] As with populations for 2015, values for each cell for 2011-2017 were obtained by interpolation using natural splines with knots placed at 2000, 2005, 2010, 2015 and 2020.

These were used as inputs to DIMAQ, enabling estimates of exposures to be obtained for each of these years respectively. For 2017, estimates of exposures were obtained from predictions from locally-varying regression models.[6] For each cell a model was fit to the values within that cell over time, with a constraint placed on the rate of change between 2016 and 2017 to avoid unrealistic and/or unjustified extrapolation of trends. Measures of uncertainty were obtained by repeating the procedure for the limits of the 95% credible intervals, again on a cell-by-cell basis.

Population-weighted exposure generation

To generate a distribution of the population-weighted ambient particulate matter, we took a weighted sampling strategy, taking samples from all grid cells in a given location. For example, for a country with n grid cells, we randomly sampled 1000 values from the n (grid cells) x 1000 (samples) where the probability of being sampled was proportional to the population of that grid cell.

Theoretical minimum-risk exposure level

The TMREL was assigned a uniform distribution with lower/upper bounds given by the average of the minimum and 5th percentiles of outdoor air pollution cohort studies exposure distributions conducted in North America, with the assumption that current evidence was insufficient to precisely characterise the shape of the concentration-response function below the 5th percentile of the exposure distributions. The TMREL was defined as a uniform distribution rather than a fixed value in order to represent the uncertainty regarding the level at which the scientific evidence was consistent with adverse effects of exposure. The specific outdoor air pollution cohort studies selected for this averaging were based on the criteria that their 5th percentiles were less than that of the American Cancer Society Cancer Prevention II (CPSII) cohort's 5th percentile of 8.2 based on Turner et al. (2016).[7] This criterion was selected since GBD 2010 used the minimum, 5.8, and 5th percentile solely from the CPS II cohort. The resulting lower/upper bounds of the distribution for GBD 2017 were 2.4 and 5.9. This has not changed since GBD 2015.

Relative risks and population attributable fractions

We estimated the Ambient Air Pollution-attributable burden of disease based on the relation of long-term exposure to PM2.5 with Ischemic Heart Disease, stroke (ischemic and hemorrhagic), COPD, lung cancer and acute lower respiratory infection. These were also the pollutant-outcome pairs used to estimate the Ambient Air Pollution attributable burden since GBD 2010. For GBD 2017 we also added Type II Diabetes as an outcome of ambient air pollution. We used results from all cohort studies published as of July 2018 that reported cause-specific relative risk estimates based on measured or modelled PM2.5 and that adjusted for potential confounding due to other major risk factors such as tobacco smoking using data for each study participant.

Bowe et al. recently published work that assembled the evidence for the relationship between particulate matter and diabetes to generate IER curves and attributable burden estimates based on methodologies similar to those of the GBD. [8]

When generating the IER for Type II Diabetes, we included all eight of the studies summarized by Bowe et al. in addition to six other cohorts. Resulting attributable burden estimates were remarkably similar to GBD 2017 results. All citations for studies used in the fitting of the IER curve can be found using the GBD 17 Data Input Sources Tool.

Integrated exposure response function

The Integrated Exposure Response Function (IER) was created to ascertain the shape of the dose response curve for a variety of health outcomes across a wide range of exposure to PM2.5. The IER model is fit by integrating RR information from studies of outdoor air pollution (OAP), Second hand tobacco smoke (SHS), Household Air Pollution (HAP), and Active Smoking (AS). Because OAP studies are often performed at the lower end of the ambient air pollution range, incorporating other exposures to particulate matter enables RR estimation across the global range of exposure. These methods have been described in detail elsewhere.[9,10]

Notable changes for GBD 2017 include added studies for OAP, SHS, and HAP, updated literature reviews for AS studies, and more informative priors to stabilize the shape of the IER curves.

- We added all newly published cohorts of long-term exposure to Ambient PM2.5 and incidence or mortality due to IHD, stroke, COPD, lung cancer, and LRI. One notable addition was the China Male Cohort which included mortality due to IHD, Stroke, COPD, Lung Cancer, and Diabetes (unpublished analysis).[11] This study represented a higher exposure range than most of our previously incorporated studies with 5th and 95th percentile of 15.5 and 77.1 micrograms/m^3. For Type II Diabetes, the new outcome included in GBD 2017, we included all cohorts which measured long-term PM2.5 exposure and incident diabetes or mortality due to diabetes.
- We did not change the SHS input studies with the exception of including all studies from a recent meta-analysis examining the relationship between SHS and Type II Diabetes.[12] We also added seven studies found from a systematic review examining SHS exposure and COPD. We had previously not included SHS in the formation of this curve.
- We added four cohort studies of HAP and any of our measured outcomes. Previously we have only included which measured levels of PM2.5 exposure. To incorporate cohort studies with binary exposure data (presence or absence of solid-fuel use for cooking) we used the PM2.5 mapping function (see Household Air Pollution Appendix for more details) to obtain a PM2.5 level attributed to solid fuel use for cooking for the location-year of the study (Exp_{HAP}). We also used the OAP exposure model to obtain an OAP PM2.5 level for the location-year (Exp_{OAP}). The study RR was used to inform the curve on the range of Exp_{OAP} to (Exp_{OAP} + Exp_{HAP}).
- For all outcomes, we used updated systematic reviews of the literature performed by the GBD smoking team for studies examining cigarettes smoked per day and the six IER outcomes to inform the high exposure range of the curve. The smoking team found that the process of systematic review and inclusion of all acceptable studies led to lower relative risks.
- To help obtain more reasonable curve fits, we added more informative priors to two of three IER function parameters in the MCMC Bayesian fitting process.

Limitations

It is important to recognize the inherent limitations of the IER approach. The use of various sources to construct a risk curve assumes an equitoxicity of particles, consistent with evaluations by US EPA and WHO. However, current evidence suggests there are differences in health impact by source, size, and chemical composition. This is seen when comparing studies of ambient and household particulate matter. As this body of evidence grows, we will continue to re-examine our strategy for the integrated exposure-response curve. For now, the IER is a practical solution to fill gaps in the literature where we do not have sufficient evidence such as household air pollution exposures and ambient in highly polluted areas.

Additionally, currently the exposure concentrations used for both SHS and AS data points when fitting the IER are contrasted with the TMREL and do not take into account ambient particulate matter pollution. In future iterations of fitting the curve, we will test alternate approaches, including a similar approach to HAP, allowing each data point to inform the curve on the range of Exp_{OAP} to (Exp_{OAP} + $Exp_{AS/SHS}$).

Relative risk and proportional PAF approach

For GBD 2017 we developed a new approach to use the IER for obtaining PAFs for both OAP and HAP. Previously, relative risks for both exposures were obtained from the IER as a function of exposure and relative to the same TMREL. In reality, were a country to reduce only one of these risk factors, the other would remain. We failed to consider the joint effects of particulate matter from outdoor exposure and burning solid fuels for cooking.

In GBD 2017, relative risks were still estimated from the output of the IER curve. Everyone is exposed to some level of OAP, but only a proportion of the population in each location-year use solid cooking fuel and are exposed to HAP. For the proportion of the population not exposed to HAP the relative risk was obtained by $RR_{OAP} = IER(z = Exp_{OAP})$ and used to calculate the PAF for each location based on the population-weighted exposure.

For the proportion of the population exposed to both OAP and HAP, we calculated a joint relative risk from the IER by $RR_{OAP+HAP} = IER(z = Exp_{OAP}+Exp_{HAP})$. This joint relative risk is used to calculate a joint PAF for each location. PAF calculation is detailed in the methods appendix. For each location, we proportioned the joint PAF based on the proportion of exposure due to OAP and HAP respectively. See the table below for equations used to calculate proportional PAFs.

PAF	**Population not exposed to HAP**	**Population exposed to HAP**
OAP	PAF_{OAP}	$(Exp_{OAP}/(Exp_{OAP}+Exp_{HAP}))*PAF_{OAP+HAP}$
HAP	0	$(Exp_{HAP}/(Exp_{OAP}+Exp_{HAP}))*PAF_{OAP+HAP}$

Generally, as expected, this new strategy led to lower PAFs for both ambient and household particulate matter pollution.

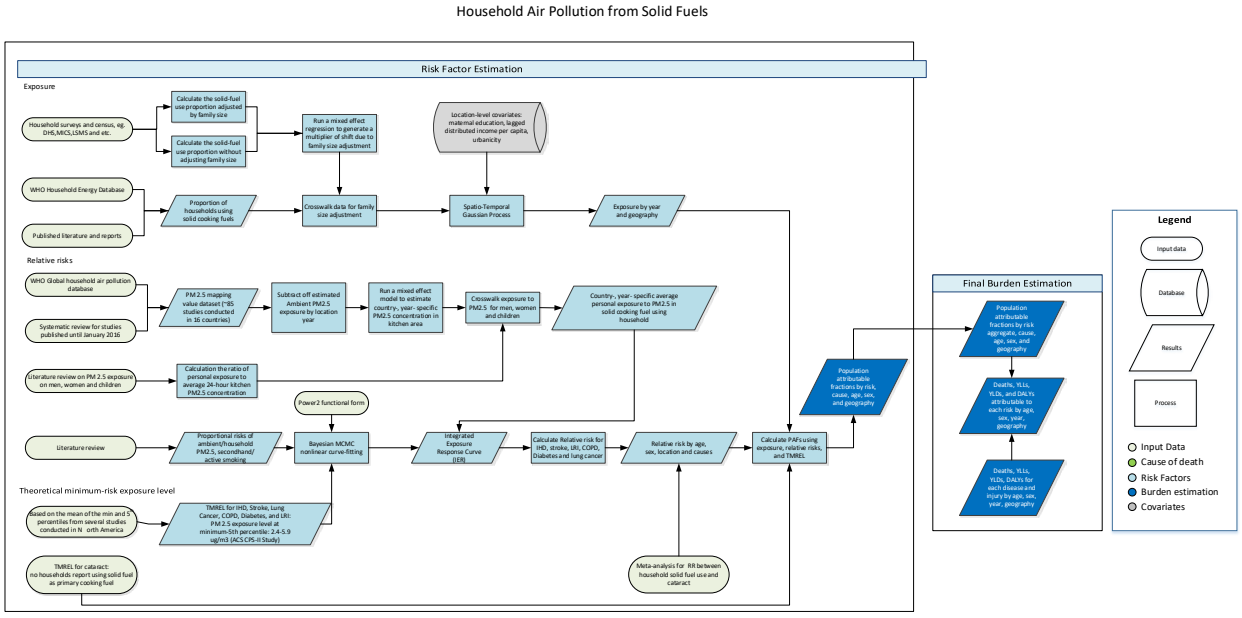
Household Air Pollution Capstone Appendix

Flowchart



Input Data & Methodological Summary

Exposure

Case definition

Exposure to household air pollution from solid fuels (HAP) is defined as the proportion of households using solid cooking fuels. The definition of solid fuel in our analysis includes coal, wood, charcoal, dung, and agricultural residues.

Input data

Data were extracted from the standard multi-country survey series such as Demographic and Health Surveys (DHS), Living Standards Measurement Surveys (LSMS), Multiple Indicator Cluster Surveys (MICS), and World Health Surveys (WHS), as well as country-specific survey series such as Kenya Welfare Monitoring Survey and South Africa General Household Survey. To fill the gaps of data in surveys and censuses, we also downloaded and updated HAP estimates from WHO Energy Database and extracted from literature through systematic review. Each nationally or sub-nationally representative data point provided an estimate for the percentage of households using solid cooking fuels. Estimates for the usage of solid fuels for non-cooking purpose were excluded, i.e. primary fuels for lighting. The database, with estimates from 1980 to 2017, contained about 680 studies from 150 countries. As updates to systematic reviews are performed on an ongoing schedule across all GBD causes and risk factors, an update for household air pollution will be performed in the next 1-2 iterations.

Modelling strategy

Household air pollution was modelled at household level using a three-step modelling strategy that uses linear regression, spatiotemporal regression and Gaussian Process Regression (GPR). The first step is a mixed-effect linear regression of logit-transformed proportion of households using solid cooking fuels. The linear model contains maternal education, proportion of population living in urban areas, and

lagged-distributed income as covariates and has nested random effect by GBD region, and GBD super region respectively. The full ST-GPR process is specified elsewhere this appendix. No substantial modelling changes were made in this round compared to GBD 2016.

Theoretical minimum-risk exposure level

For cataract, the TMREL is defined as no households using solid cooking fuel. For outcomes that utilise evidence based on the Integrated Exposure Response (IER), the TMREL is defined as uniform distribution between 2.4 and 5.9 ug/m^3.

Relative risks

In addition to the previously included outcomes of lower respiratory infections (LRI), stroke, Ischemic Heart Disease (IHD), Chronic Obstructive Pulmonary Disease (COPD), lung cancer, and cataract, in GBD 2017 we added Type II Diabetes as a new outcome of household air pollution. The relative risk for cataracts was extracted from a meta-analysis and is 2.47 with 95% (1.61, 3.73).[1] GBD currently only estimates cataracts as an outcome for females.

In GBD 2017, we adopted a new approach for risk attribution using the Integrated Exposure-Response Function (IER). Updates to the IER and the new joint-estimation PAF approach is described in the Ambient Particulate Matter appendix.

$PM_{2.5}$ mapping value

In order to use the IER curve, we must estimate the exposure to particulate matter with diameter of less than 2.5 micrometers ($PM_{2.5}$). Since GBD 2015 we have been using a mapping model relying on a database of now almost 90 studies which measures $PM_{2.5}$ exposure in households using solid cooking fuel. Using socio-demographic index and study-level factors as covariates, we predict exposure for all location-years.

In GBD 2017, we updated the model to estimate the individual exposure to $PM_{2.5}$ over and above ambient levels due to the use of solid cooking fuel. We did this by subtracting off the estimated ambient level $PM_{2.5}$ for the location-year of each study in the database before inputting them into the model. By doing this we have independent estimates for $PM_{2.5}$ exposure due to ambient and household solid fuel use.

These exposures are cross-walked to values for men, women, and children by generating the ratio of each group's mean exposure to the overall mean personal exposure. The resulting location, year, sex, and age specific $PM_{2.5}$ exposure values are used as inputs in the IER and attributable burden calculation process.

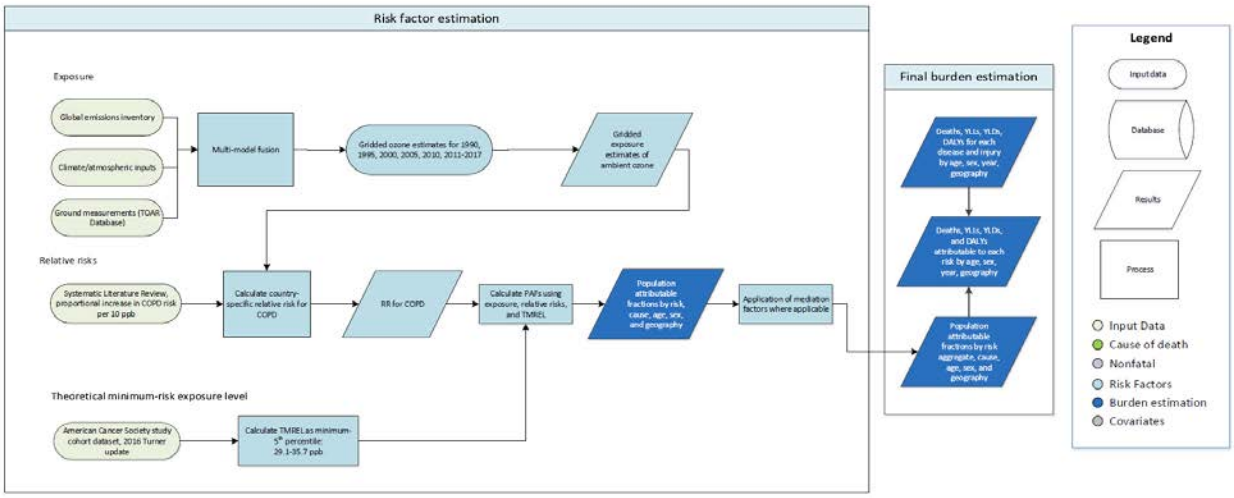
Ambient Ozone Pollution Capstone Appendix

Flowchart



Input data and methodological summary

Exposure

Case definition

For GBD 2017, exposure to ozone pollution is defined as the seasonal (6 month period with highest mean) 8 hour daily maximum ozone concentrations, measured in ppb. This was an update from the previous exposure metric in accordance with an update of the American Cancer Society Cancer Prevention Study II (ACS CPS-II).[1]

Input data

Previously, exposure estimates were based on a chemical transport model with no measurement database or evaluation. In GBD 2017, exposure estimates incorporated a new comprehensive ozone measurement database (TOAR).[2] This enabled a continent-specific weighted blend of 6 chemical transport models with grid cell level bias correction. The use of ground measurements also enabled the incorporation of error estimation, where previously we had assumed a +/- 6% error. The output of this model is a global raster of ozone exposure which is a summary for the years 2008-2014.[3]

Modelling strategy for trends

To estimate ozone concentrations over time, we used the trend from the former GBD model for 1990, 2000, and 2010 and cubic splines for 1995, 2005, and 2011, after applying an adjustment for the difference in trends between the previous (1 hour daily maximum) and current (8 hour daily maximum metrics. Annualised rate of change was used to predict for the years 2012-2017.

Theoretical minimum-risk exposure level

The TMREL of ozone was updated this year based on the exposure distribution from the updated ACS CPS-II study.[1] A uniform distribution was drawn around the minimum and 5th percentile values experienced by the cohort, defined as ~U(29.1, 35.7), in ppb.

Relative risks

Since the inclusion of ozone in GBD 2010 the relative risk of ozone exposure for respiratory COPD mortality has been defined to be 1.029, 95% C.I. (1.01-1.048) per 10 ppb of ozone exposure. Note that this comes from one study that looked at all respiratory mortality.[4] For GBD 2017, we performed a literature review and included five cohorts from Canada, the UK, and the US which all measured COPD mortality. For cohorts with multiple analyses we chose the most recent analysis. We found a resulting relative risk of 1.06, 95% C.I. (1.02, 1.10).

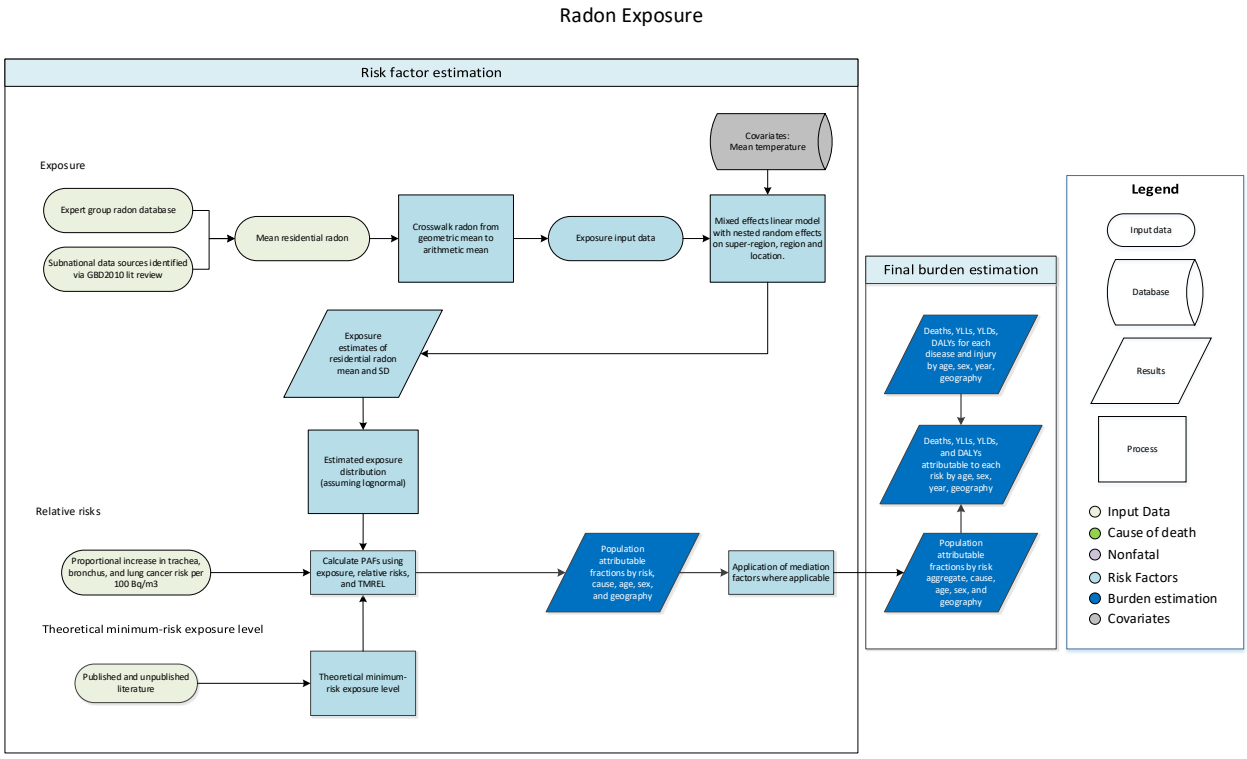
Radon Exposure Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Radon is a radioactive gas that is produced as a byproduct of the decay chain of uranium, occurring naturally within the Earth's crust. Some fraction of this natural radon production escapes into the atmosphere, where it forms at low concentration unless build-up is caused by enclosed spaces like homes, mines, or caves. Radon exposure is expressed as average daily exposure to indoor air radon gas levels measured in Becquerels (disintegrations per second) per cubic meter (Bq/m^3).

Input data

Exposure to radon is determined using values curated by an expert group. These values are taken from a variety of sources including literature, government agencies, and monitoring stations. Their methodology is then inspected to determine if they are robust enough to be considered as country-level averages. 76 data points were added for GBD 2017 including several from a study which reports on subnational variation in India. Before modelling, a crosswalk is performed from studies measuring geometric to arithmetic mean.

Modelling strategy

Because radon is naturally occurring and is not considered to have much temporal fluctuation,[1] we shifted from a spatio-temporal GPR model to a mixed effects linear model. The model included nested random effects on super-region, region, and location (most detailed) and one fixed effect covariate, long-term mean temperature as a proxy for adequate building ventilation.

We did not have the microdata necessary to use ensemble modelling to inform our radon exposure distribution, so for GBD 2017 we continued to assume a lognormal distribution. Arithmetic mean exposure estimates obtained were used to fit the lognormal distribution before applying relative risks.

Theoretical minimum-risk exposure level

The TMREL was also taken directly from literature values that were not updated for GBD 2017. Given that radon is naturally occurring, zero exposure would be impossible. As such, we continue to use a TMREL of 10 Bq/m^3, which is equivalent to the outdoor concentration of radon.[2]

Relative risks

The relative risk for radon exposure was extracted from literature values – a 2005 meta-analysis of case-control studies showing the association of radon with lung cancer.[3] This value was used in GBD 2010 and has not been changed since.

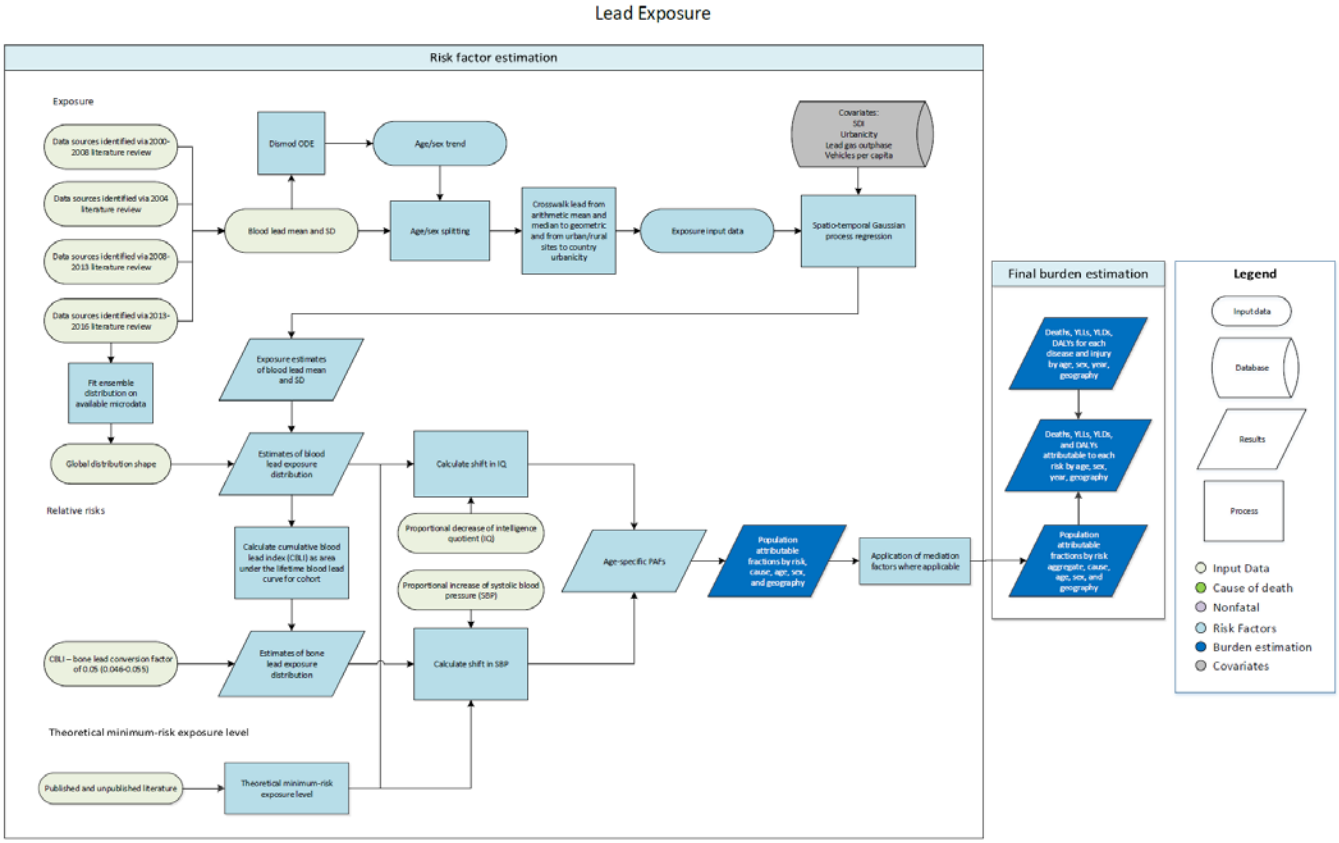
Lead Exposure Capstone Appendix

Flowchart



Definitions

Exposure to lead is defined in two different ways according to the currently known pathways of health loss. Acute lead exposure, relevant to disease burden through IQ loss in children, is measured as the micrograms of lead per deciliter of blood (µg/dL). Long-term lead exposure, relevant to disease burden in adults given the manifestation of health impact through increased systolic blood pressure and hence a decline of cardiovascular health, is measured as the accumulation of lead in the bone as micrograms of lead per gram of bone (µg/g).

Input Data

The input data for lead exposure is primarily extracted from literature regarding blood lead, in addition to a few blood lead surveys. Blood lead values are derived from studies that take blood samples and analyze them using various techniques to determine the level of lead present. Our literature review resulted in 3,183 usable data points from 554 different studies, which span the years 1970 to 2017. The database of literature values was modelled for data-sparse countries using spatio-temporal Gaussian process regression (ST-GPR). These values were used as blood lead exposure estimates. The second pathway of burden is related to bone lead exposure, which was estimated by calculating a cumulative

blood lead index for cohorts using estimated blood lead over their lifetime. The cumulative blood lead index is then used to estimate bone lead using a scalar defined in literature.[1]

Exposure Modeling

The methodology to estimate lead exposure last underwent significant change in GBD 2013. Global exposure had been previously modelled using age-integrating Bayesian hierarchal modelling (DisMod-MR). The modelling process was updated for GBD 2013 by shifting to spatial-temporal GPR methodology. This allowed for estimates of all country-age-sex-year groups for single years instead of five year periods. This approach improved the granularity of estimates for bone lead, which requires back-estimation of previous blood lead to calculate a cumulative blood lead index.

For GBD 2017, the spatio-temporal Gaussian process regression modelling methodology was updated as detailed in the appendix specific to this analytical technique, which is common to a variety of risk factors. In order to predict blood lead in country-years with insufficient data, covariates that have been produced across time and space relevant to this analysis were used. For blood lead exposure, the covariates determined to have predictive ability were the socio-demographic index (SDI), the proportion of a location's population living in urban settings (logit transformed), the combined number of 2 and 4-wheel vehicles per capita, and a covariate indicating whether leaded gasoline had been phased out in a given country-year (smoothed over the first 5 years of phase-out to reflect its gradual implementation). ST-GPR was used to produce estimates of mean and standard deviation of blood lead for all age groups, for both sexes, and for all GBD locations from 1970 to 2017.

In earlier iterations of GBD, the distribution of lead exposure was assumed to be log-normal. Since GBD 2016, ensemble modelling techniques were used to find an optimal global distribution by fitting a variety of distributions to the available blood lead microdata. This was a common update for all continuous risk factors. The ST-GPR estimates of mean and standard deviation blood lead were used with the global distribution shape to determine distributions for blood lead exposure.

To calculate blood lead over the lifetime of a given cohort, blood lead was assumed to grow linearly from 2.0 ug/dL in 1920 (see TMREL) to the value for that cohort in 1970. Using the exposure distributions of blood lead over time and space, cohorts were constructed such that lifetime blood lead could be expressed as a curve over each year of life. The area under this curve was the cumulative blood lead index, which could be used to estimate bone lead in a given year with the aforementioned scalar.

Estimating Attributable Burden

Assessment of risk-outcome pairs

We included outcomes based on the strength of available evidence supporting a causal relationship. Blood lead level (a measure of acute lead exposure) is paired with idiopathic developmental intellectual disability as modeled through the impact of blood lead levels on IQ in children. Bone lead level (a measure of cumulative lead exposure) is paired with systolic blood pressure as an outcome, and subsequently to all cardiovascular outcomes to which systolic blood pressure is paired, which includes rheumatic heart disease, ischemic heart disease, ischemic stroke, intracerebral hemorrhage, hypertensive heart disease, other cardiomyopathy, atrial fibrillation and flutter, aortic aneurysm, peripheral artery disease, endocarditis, other cardiovascular and circulatory diseases, chronic kidney

disease due to hypertension, chronic kidney disease due to glomerulonephritis, and chronic kidney disease due to other and unspecified causes.

Theoretical minimum-risk exposure level

In previous iterations of GBD, the TMREL was taken from literature estimates of pre-industrial blood lead in humans.[2] That value was estimated at 2.0 ug/dL. The decision was made that the TMREL of blood lead could not be 0 given the ambient sources of lead that would be impossible to eliminate.[3]

However, average blood lead exposures in a number of countries have fallen below 2.0 ug/dL in the past few years, suggesting that the TMREL ought to be lowered. Unfortunately, we were not able to find literature with statistically significant estimates for relative risk at such low levels of blood lead exposure. As a result, we have continued to use a TMREL of 2.0 ug/dL for GBD 2017.

Relative Risks

Because the relative risk of IQ loss from lead exposure is specific to children, in GBD 2015 no burden of lead via IQ loss was estimated in the population aged 15 and above. To better account for the continued burden of past lead exposure on IQ in older age groups, since GBD 2016 we have constructed cohorts from the entire population. Estimates of a cohort's lead exposure in early childhood (at 24 months of age) were used to determine past IQ loss, and thus calculate burden via the impact on concurrent IQ in the older population.

Blood lead relative risks were previously taken from a 2005 pooled analysis that was first incorporated in GBD 2010.[4] For GBD 2017, blood lead relative risks have been updated with a 2013 re-analysis of the findings of that 2005 paper, providing slightly adjusted relative risk estimates specific to exposure at 24 months of age.[5] The bone lead relative risks were taken from a 2008 meta-analysis that was updated for GBD 2010.[6]

Population Attributable Fraction

We used the standard GBD population attributable fraction (PAF) equation to calculate PAFs for bone lead exposure and each of its paired outcomes using exposure estimates and relative risks. We used a similar approach for estimating PAFs for the burden of intellectual disability attributable to blood lead, which uses the estimated distribution of intellectual disability and the modeled shifts in IQ due to blood lead levels to determine the PAF.

Occupational Risk Factors Capstone Appendix

Exposure definitions

The following definitions were used for occupational risk factor exposures. All exposures were estimated for ages 15 and older.

Occupational Asbestos	Cumulative lifetime exposure to occupational asbestos, using mesothelioma death rate as an analogue
Occupational Asthmagens	Proportion of the working population exposed to asthmagens, based on population distributions across nine occupational categories
Occupational Carcinogens (arsenic, benzene, beryllium, cadmium, chromium, diesel engine exhaust, formaldehyde, nickel, polycyclic aromatic hydrocarbons, silica, sulfuric acid, and trichloroethylene)	Proportion of the population that was ever occupationally exposed to carcinogens at high or low exposure levels, based on population distributions across seventeen economic activities
Occupational Ergonomic Factors	Proportion of the working population exposed to low back pain-inducing work, based on population distributions across nine occupational categories
Occupational Injuries	Proportion of injuries in the working-age population attributable to occupational work, based on fatal injury rates in seventeen economic activities
Occupational Noise	Proportion of the population occupationally exposed to 85+ decibels of noise, based on population distributions across seventeen economic activities
Occupational Particulates	Proportion of the population occupationally exposed to particulates, based on population distributions across seventeen economic activities

Economic activities and occupations were coded according to the following categories:

Economic Activities	**Occupations**
Agriculture, hunting, forestry	Legislators, senior officials, and managers
Fishing	Professionals
Mining and Quarrying	Technicians and associate professionals
Manufacturing	Clerks
Electricity, gas, and water	Service workers and shop/market sales workers
Construction	Skilled agricultural and fishery workers
Wholesale and retail trade/repair	Plant and machine operators and assemblers
Hospitality	Craft and related workers

Transport, storage, and communication	Elementary occupations
Financial intermediation	
Real estate/renting	
Public administration/defense; compulsory social security	
Education	
Health and social work	
Other community/social/personal service activities	
Private households	
Extra-territorial organisations/bodies	

Input data

Primary inputs were obtained from the ILO,[1-4] and included raw data on economic activity proportions, occupation proportions, fatal injury rates, and employment to population ratio estimates. A systematic web review was conducted in order to collect the underlying microdata from the ILO's estimates to aid in re-extraction at greater levels of granularity. Where freely available, survey datasets were downloaded from the survey organisations in question. Other datasets were obtained through submission of requests to agencies and through the GBD collaborator network. Microdata was tabulated in order to create survey-weighted estimates of economic activities and occupations for the GBD geographies and years. Various classification systems were crosswalked to ISIC Rev.3 (for economic activities) and ISCO 1988 (for occupations). Subnational estimates for UK and China were added to the datasets for economic activities and occupations.[5,6]

For occupational asbestos, primary inputs were obtained through GBD 2017 cause of death estimates and published studies.[7,13,14]

Uncertainty for inputs where microdata was unavailable was generated by fitting a Loess curve to the data and determining the standard deviation of the data from the fitted curve.

Modelling strategies

A Spatio-temporal Gaussian process regression (ST-GPR) was used to generate estimates for all years and locations for the primary inputs. Study level covariates used in the prior model were education in years per capita, geological covariates (for mining models), the proportion of the population living with access to a coastline (for fishing models), the IHME socio-demographic index (SDI), the mean temperature/latitude (for agriculture models), and the proportion of the population living in urban areas. Space-time parameters were chosen by maximising out-of-sample cross-validation and minimising RMSE. For economic activity and occupation proportions, estimates from ST-GPR were then re-scaled to sum to 1 across categories by dividing each estimate by the sum of all the estimates.

The following sections describe the modelling approaches for each occupational risk's exposure prevalence.

Occupational carcinogens, occupational noise, and occupational particulates

Prevalence of exposure to these risks was determined using the following equation:

$$Prevalence\ of\ Exposure_{c,y,s,a,r,l} = \sum_{EA} Proportion_{EA,c,y} * EAP_{c,y,s,a} * Exposure\ rate_{EA,r,l,d}$$

where:

EAP = economically active population	c = country	r = risk
EA = economic activity	d = duration	s = sex
a = age	l = level of exposure	y =year

Exposure rate was provided by expert group recommendations and literature[8-11] (see table 1). The CAREX database was used in order to quantify the association between exposure by industry/carcinogen to SDI across all the countries in the database. This effect was used to predict exposure in countries that were not included in CAREX. Duration was considered for occupational carcinogens through application of occupational turnover factors[12] and for occupational noise and particulates by calculating cumulative exposure as the average exposure over the lifetime (the past 50 years) for each age/sex cohort.

Occupational ergonomic factors and occupational asthmagens

Prevalence of exposure to these risks was determined using the following equation:

$$Prevalence\ of\ Exposure_{c,y,s,a,r} = \sum_{EA} Proportion_{OCC,c,y} * EAP_{c,y,s,a}$$

where:

EAP = economically active population	c = country	r = risk
OCC = occupation	a = age	s = sex
		y = year

Occupational injuries

Occupational injury counts were estimated using the following equation:

$$Occupational\ fatal\ injuries_{c,y,a,s} = \sum_{EA} Injury\ rate_{EA,c,y,s} * Population_{c,y,a,s} * EAP_{c,y,s,a} * Proportion_{EA,c,y}$$

where:

EAP = economically active population	c = country	y = year
EA = economic activity	a = age	s = sex

Occupational asbestos

Prevalence of exposure to asbestos was estimated using the asbestos impact ratio (AIR), which is equivalent to the excess deaths due to mesothelioma observed in a population divided by excess deaths due to mesothelioma in a population heavily exposed to asbestos. Formally, this is defined using the following equation:

$$AIR = \frac{Mort_{c,y,s} - N_{c,y,s}}{Mort^{*}_{c,ys,} - N_{c,y,s}}$$

where:

Mort = Mortality rate due to mesothelioma
Mort* = Mortality rate due to mesothelioma in population highly exposed to asbestos
N = Mortality rate due to mesothelioma in population not exposed to asbestos

c = country
y = year
s = sex

Mortality rate due to mesothelioma was estimated from GBD 2017 causes of death.[7] Mortality rate due to mesothelioma in populations not exposed to asbestos was calculated using the model in Lin et al.,[13] while the mortality rate due to high exposure to asbestos was estimated in Goodman et al.[14] Asbestos exposure prevalence created using the AIR was used to estimate PAFs for all asbestos-associated causes except for mesothelioma. Custom PAFs were calculated for mesothelioma by using the ratio of the excess mortality with respect to an unexposed population (Mort – N) divided by the mortality rate in the population in question (Mort). This calculation assumes that all mesothelioma is a product of occupational asbestos exposure and could potentially over-estimate burden due to occupational asbestos exposure in populations with high non-occupational asbestos exposure.

Theoretical minimum-risk exposure level

For all occupational risks, with the exception of occupational asbestos, the theoretical minimum-risk exposure level was assumed to be no exposure to that risk.

Relative risk

Relative risks were obtained for all occupational risks by conducting a systematic review of published meta-analysis. The estimates used, as well as the associated studies, are reported by category group in appendix table 5.

PAFs

For all occupational risks, with the exception of injuries (outlined below) and mesothelioma (outlined above), PAFs were calculated using the prevalences estimated above, using the PAF formula in outlined in the GBD 2017 methods appendix.

Occupational injuries PAF

The PAFs for occupational injuries were calculated using the following formula:

$$PAF_{c,y,a,s} = \frac{Occupational\ fatal\ injuries_{c,y,a,s} - TMREL}{Fatal\ injuries_{c,y,a,s}}$$

where:

c = country
y = year
a = age
s = sex

Fatal injury totals were obtained from GBD 2017 causes of death.[7]

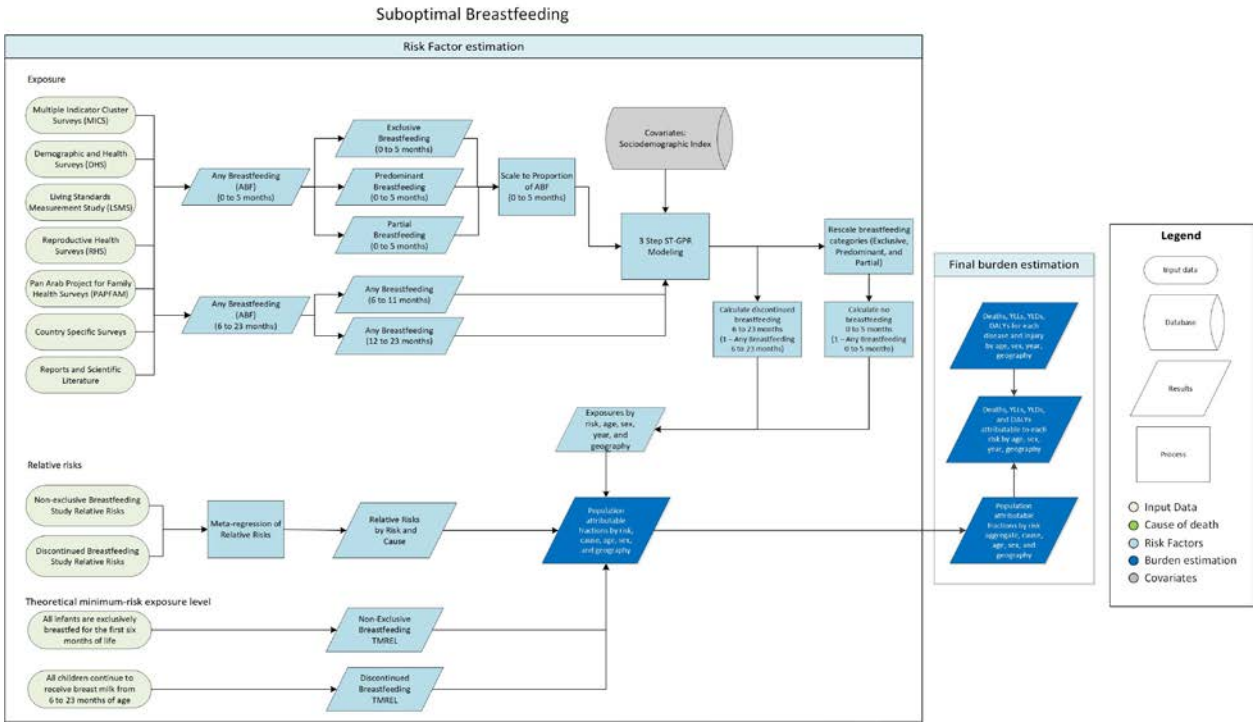
Suboptimal Breastfeeding Capstone Appendix

Flowchart



Definitions

Exposure to suboptimal breastfeeding is composed of 2 distinct categories: non-exclusive breastfeeding and discontinued breastfeeding.

Non-exclusive breastfeeding is defined as the proportion of children under 6 months of age who are not exclusively breastfed. We then parse those not exclusively breastfed into 3 categories – predominant, partial, and no breastfeeding. Exclusive breastfeeding is defined as the proportion of children who receive no other food or drink except breast milk (allowing for ORS, drops, or syrups containing vitamins, minerals, or medicines). Predominant breastfeeding is the proportion of children whose predominant source of nourishment is breastmilk but also receive other liquids. Partial breastfeeding refers to those infants who receive breastmilk as well as food and liquids, including non-human milk and formula. No breastfeeding refers to infants who do not receive breast milk as a source of nourishment.

Discontinued breastfeeding is defined as the proportion of children between 6 to 23 months who receive no breast milk as a source of nourishment.

Input Data

We made substantial exposure data updates for GBD 2017, including extracting identified surveys not included in previous rounds and re-extracting all surveys for new GBD 2017 subnational locations. We searched the Global Health Data Exchange (GHDx) database for sources using the keyword "Breastfeeding." Of 2,026 potential sources identified, we extracted 1,081 unique country-years of data (2,262 unique geography-years, including subnational geographies) that met our inclusion criteria. The

data used in the analysis consists mostly of processed individual-level microdata from surveys; in the cases where microdata was unavailable, we used reported tabulated data from survey reports and scientific literature. Data used to categorize type of non-exclusive breastfeeding (predominant, partial, and none) come from surveys with 24-hour dietary logs based on maternal recall.

Exposure Modelling

Using the processed microdata and tabulated data from reports, we generated a complete time series from 1980 to 2017 for the prevalence of breastfeeding patterns for children 0 to 5 months and 6 to 23 months using a three-step spatio-temporal Gaussian process regression modelling process.

First, we estimated a robust linear regression using each geography's sociodemographic index as a covariate. The following linear model was used for the estimation of breastfeeding indicators:

$$logit\left(P_{x,c,t}\right) = \beta_0 + \beta_1 SDI_{\mathrm{c,t}} + \alpha_c + \gamma_{R[c]} + \omega_{\mathrm{SR[c]}} + \varepsilon_{c,t}$$

where $P_{x,c,t}$ is prevalence for breastfeeding category *x* in country c and year t; $SDI_{c,t}$ is value of the Sociodemographic Index for country c and year t; α_c, $\gamma_{R[c]}$, and $\omega_{\mathrm{SR[c]}}$ are country, region, and super-region random intercepts, respectively.

We then followed this with a spatio-temporal regression that uses the residuals of the predictions from the linear regression to perform a locally-weighted regression that provides a greater weighting factor to those nearer in space and time. The predicted residuals from this step are then added to those created in the linear regression step.

Finally, we run a Gaussian process regression that incorporates the variance of the input data as well as the variance of the model predictions. It uses predictions from the spatio-temporal regression as the mean function and generates draws from a multinomial distribution (based on the data uncertainty in the prior) to generate the final prevalence estimates and their confidence intervals.

We estimated six models to produce each of our categories: the proportion of currently breastfeeding infants 0-5 months of age, the ratio of infants exclusively breastfed to breastfed infants 0-5 months of age, the ratio of infants predominantly breastfed to breastfed infants 0-5 months of age, the ratio of infants partially breastfed to breastfed infants 0-5 months of age, the proportion of currently breastfeeding infants 6-11 months of age, and the proportion of currently breastfeeding infants 12-23 months of age. We convert the ratios of exclusive, predominant, and partial breastfeeding to the total category prevalence proportions by multiplying each ratio by the estimates of any breastfeeding among infants aged 0-5 months. This ensures that these categories sum correctly to the "any breastfeeding 0-5 months" envelope. We calculate the proportion of infants receiving no breastmilk 0-5 months of age by subtracting the estimates of current breastfeeding from 1. We perform the same operation to estimate discontinued breastfeeding in the 6-11 months and 12-23 months categories.

Estimating Attributable Burden

Assessment of risk-outcome pairs

We included outcomes based on the strength of available evidence supporting a causal relationship. Studies evaluating the causal evidence for our risk-outcome pairs came primarily from articles found in a review published by the World Health Organization.[1] Non-exclusive breastfeeding was paired with diarrhea and lower-respiratory infection as diseases outcomes. Discontinued breastfeeding was paired with diarrhea as an outcome.

Theoretical minimum-risk exposure level

For non-exclusive breastfeeding, those children that received no source of nourishment other than breastmilk ("exclusively breastfed") were considered to be at the lowest risk of any of the disease outcomes. For discontinued breastfeeding, we assumed that children aged 6 to 23 months who received any breastmilk as a source of nourishment to be at the lowest risk of disease outcome.

Relative Risks

We estimate relative risks for both non-exclusive and discontinued breastfeeding in a meta-analysis using relative risks from studies compiled in a published review by the World Health Organization.[1]

Population Attributable Fraction

We use the standard GBD population attributable fraction (PAF) equation to calculate PAFs for non-exclusive breastfeeding and discontinued breastfeeding and each of their paired outcomes using exposure estimates and relative risks.

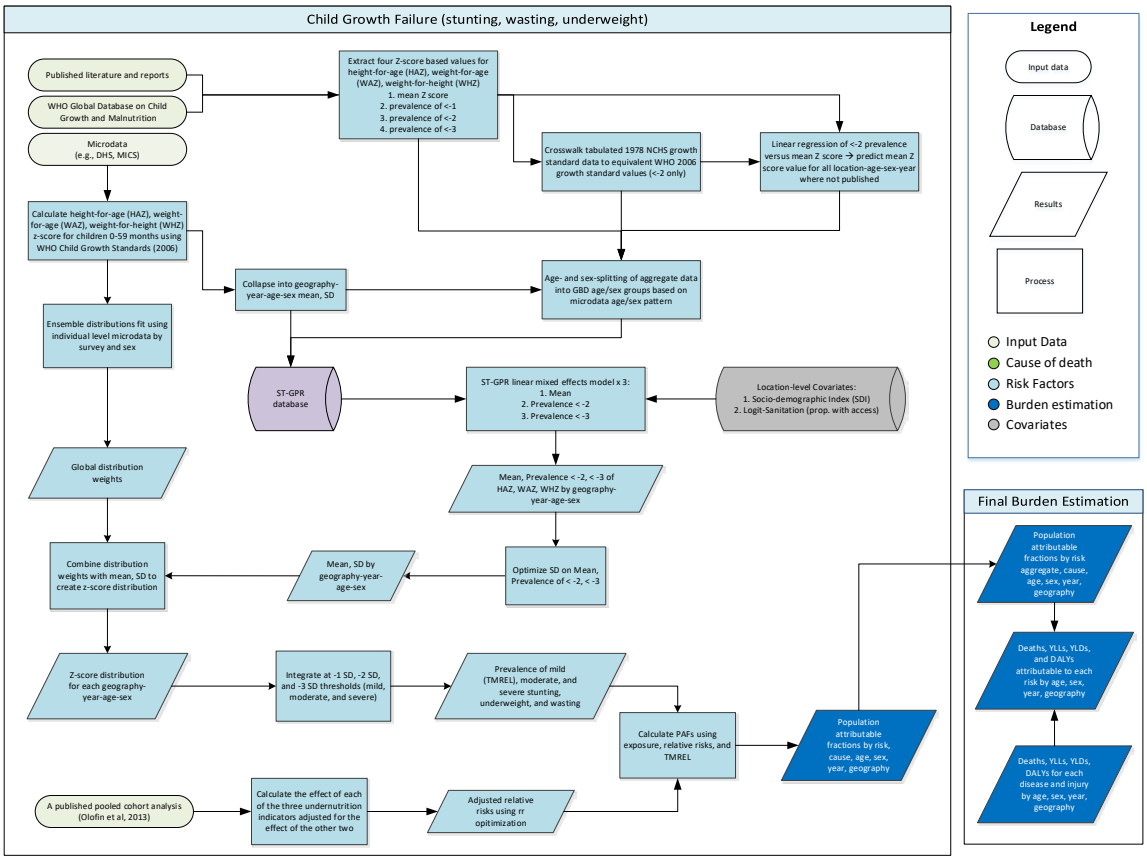
Child Growth Failure Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Child growth failure is estimated using three indicators, stunting, wasting, and underweight, all of which all of which are based on categorical definitions using the WHO 2006 growth standards for children 0-59 months. Definitions are based on Z scores from the growth standards, which were derived from an international reference population. Mild, moderate, and severe categorical prevalences were estimated for each of the three indicators.

Input data

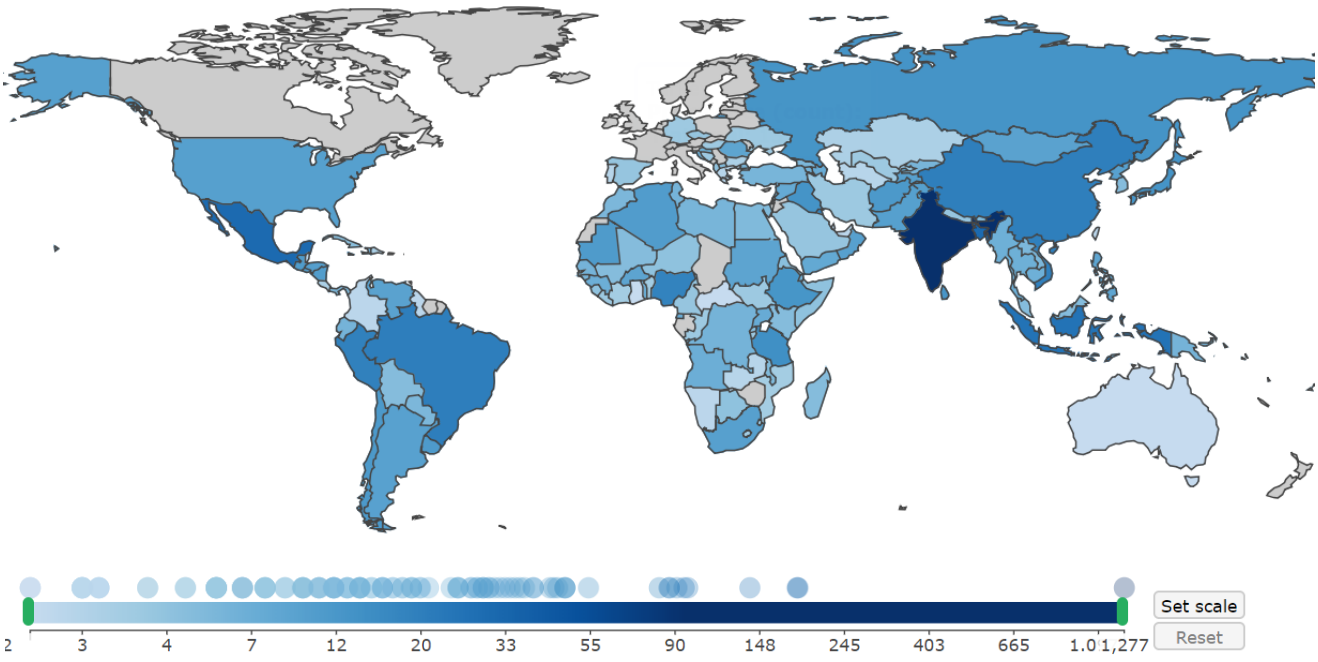
There are three main inputs for the GBD child growth failure models: microdata from population surveys and tabulated data from reports, published literature, and the WHO Global Database on Child Growth and Malnutrition.[1] The primary data additions in GBD 2017 for child growth failure were from population surveys that include anthropometry. Population surveys include a variety of multi-country and country-specific survey series such as Multiple Indicator Cluster Surveys (MICS), Demographic and Health Surveys (DHS), Living Standards Measurement Surveys (LSMS), and the China Health and Nutrition Survey (CHNS), as well as other one time country specific surveys such as the Indonesia Family Life Survey and the Brazil National Demographic and Health Survey of Children and Women. These microdata contain information

about each individual child's age (from which age in weeks and age in months are calculated), as well as height and/or weight. From that information, a height-for-age z-score (HAZ), weight-for-age z-score (WAZ), and weight-for-height z-score (WHZ) are calculated using the WHO 2006 Child Growth Standards and the LMS method.[2]

All available data from the WHO Global Database on Child Growth and Malnutrition was extracted for GBD 2016 – much of which is from published studies. Exclusions included examination date prior to 1985, non-population representative studies, and those based on self-report. A systematic literature review was last completed in GBD 2010. We looked for four metrics from all sources with tabulated data: mean Z score, prevalence <-1 Z score (mild), prevalence <-2 Z score (moderate), and prevalence <-3 Z score (severe). All data for each metric was extracted for each of stunting (height-for-age Z score; HAZ), wasting (weight-for-height Z score; WHZ), and underweight (weight-for-age Z score; WAZ).

To maximise internal-consistency and comprehensiveness of the modelling dataset, we performed three data transformations. First, any data that were reported using the National Center for Health Statistics (NCHS) 1978 growth standards were crosswalked to corresponding values on the WHO 2006 Growth Standards curves based on a study that evaluated growth standard concordance.[3] Crosswalks from 1978 to 2006 growth standards were performed only on <-2 (i.e. moderate) prevalence data as that is where the concordance was most consistent. Second, for any study that lacked a measure of mean Z score for any of stunting, wasting, or underweight, we predicted a mean value for that study based on an ordinary-least squares regression of mean Z score versus <-2 prevalence for that metric from all sources where both were available. Third, any data that was presented as both sexes combined or for 0-59 months combined, we used the age and sex pattern from all data sources that included that detail to split into corresponding and age- and sex-specific data. All data was uploaded to a database and all inputs are catalogued in the Global Health Data Exchange (http://ghdx.healthdata.org). A representative dataset coverage map for moderate stunting is shown below.

Figure 1: Number of data points in moderate stunting (<-2 HAZ) in males, 1990 to 2017



Modelling strategy

Exposure estimation

The following three-step modelling process was applied to each of stunting, wasting, and underweight.

First, all microdata was fit using an ensemble modelling process, a modelling framework developed for GBD 2016 that is described elsewhere in this appendix. A series of 12 individual distributions (normal, log normal, log logistic, exponential, gamma, mirror gamma, inverse gamma, gumbel, mirror gumbel, Weibull, inverse Weibull, and beta) were fit to the entire set of microdata (approximately 2.5 million individual z-scores) at the individual survey level. A weighting algorithm combined each distribution to find the optimal combination of these distributions for each survey, minimising the absolute prediction error across the entire distribution. Ensemble weights for each survey were then averaged across all surveys to produce a single set of global weights of the ensemble distributions. Weights were different for each sex, but invariant across geography, time, and age group. All component distributions that were used to derive weights were parameterised using "method of moments," meaning that each corresponding probability density function (PDF) could be described as a function of the mean and variance of the quantity of interest.

Second, models were developed for mean Z scores and prevalence of moderate and severe growth failure. Individual level microdata were collapsed to calculate three metrics: mean z-score, moderate prevalence, and severe prevalence. These data were combined with that derived from literature, GHDx review, and the WHO Global Database on Child Growth and Malnutrition. Each of the three metrics was then modelled using spatiotemporal Gaussian process regression (ST-GPR), a common modelling framework used across GBD, generating estimates for each age-group, sex, year, and location. Location-level covariates used in all models included Socio-demographic Index (SDI) and logit-transformed proportion of households with improved sanitation.

Third, we combined estimates of mean, prevalence (moderate and severe) with ensemble weights in an optimisation framework in order to derive the variance that would best correspond to the predicted mean and prevalence. This variance was then paired with the mean and, using the method of moments equation for each of the component distributions of the ensemble, PDF of the distribution of Z-scores were calculated for each location, year, age-group, and sex. PDFs were integrated to determine the prevalence between -1 and -2 Z scores (mild), between -2 and -3 Z scores (moderate), and below -3 Z scores (severe). These were categorical exposures used for subsequent attributable risk analysis.

Ad-hoc data exclusions were limited. In some cases, we identified surveys with evidence of data entry issues (e.g. weights entered in a mixture of pounds and kilograms) that could not be corrected and these data were outliered. We initially ran all models with the complete dataset. Data plausibility inspection began with examination of time trends in stunting. If a given datum was judged to have led to a change in the prevalence of moderate stunting in 1-4 year olds of 50% or greater in 5 years or fewer, and was inconsistent with data prior to and after that year (a change considered implausible), we outliered the offending datum and reran the model. We then further visually-inspected the results of moderate stunting, wasting, and underweight in parallel to look for location-age-sex-years where the results were not internally-consistent (e.g. stunting and wasting decreasing, underweight rapidly increasing). This inspection revealed very few inconsistent data.

Improvements from GBD 2015 to GBD 2016/ 2017

In GBD 2017, the primary changes from GBD 2016 were the 1) addition of a significant volume of new survey data, 2) crosswalking instead of down-weighting data based on NCHS 1978 growth standard, 3) utilisation of updated versions of location-level covariates, and 4) utilisation of an updated version of the ST-GPR modelling framework that empirically derives many of the modelling parameters.

There are several important differences from the GBD 2015 analysis. First, our systematic data searching efforts led to an approximately 30% increase in the number of data sources since GBD 2015, including a significant increase in data sources for Oceania, Latin America, and South Asia. Most notable was the increase in data for India through our collaboration with the India Council for Medical Research (ICMR) and Public Health Foundation of India (PHFI). Second, while GBD 2015 also used ST-GPR to model growth failure, models were completed for a single 0-5 age group, followed by application of a pooled uniform age-sex split which resulted in the implicit assumption that the age pattern of growth failure is invariant over time and geography. GBD 2016 estimates, owing to smaller sample sizes in younger age groups, do have wider uncertainty in those age groups. Third, GBD 2015, like all analyses of growth failure before it, assumed that high-income countries had zero prevalence of child growth failure. We suspended this assumption in GBD 2016 as it is not accurate and instead made explicit estimates of growth failure in all locations. Fourth, GBD 2015 did not use an ensemble approach or estimate the entire distribution of Z scores. Fifth, we changed the name of this risk factor category changed from childhood undernutrition to child growth failure to more explicitly identify the specific aspects of childhood undernutrition that are covered by the three component indicators.

Theoretical minimum-risk exposure level

Theoretical minimum risk exposure level (TMREL) for underweight, stunting, and wasting was assigned to be greater than or equal to -1 SD of the WHO 2006 standard weight-for-age, height-for-age, and weight-for-height curves respectively. This has not changed since GBD 2010.

Relative risks

The final list of outcomes paired with child growth failure risks included lower respiratory infections (LRI), diarrhea, measles, and protein energy malnutrition (PEM) as shown in Table 1. These were derived from a pooled cohort analysis by Olofin and colleagues.[5]

There is a high degree of correlation between stunting, wasting, and underweight. Failing to account for their covariance and assuming independence would overestimate the total burden significantly. This is the main reason that GBD 2010 only included childhood underweight. In GBD 2013, a method was developed to adjust observed RRs of Olofin and colleagues by simulating the joint distribution of the three indicators using the distribution of each indicator and covariance between indicators in the countries included in the meta-analysis (extracted from Demographic and Health Survey (DHS) micro-data).[4] Based on the analysis done by McDonald and colleagues, we assumed there is an interaction between the three indicators, and extracted the interaction terms from the corresponding analysis. We calculated the adjusted RRs by minimising the error between observed crude RRs (from meta-analysis) and expected crude RRs derived from adjusted RRs.

Of historical note, URI and otitis media were included as outcomes in the GBD 2013 risk analysis, based on the “analogy” causal criterion, assuming there is similar pathway as LRI outcome. However, closer review for GBD 2015 did not find sufficient evidence to support their inclusion and they were excluded, a decision that was carried forward into GBD 2016. We also attributed 100% of PEM to childhood wasting

and underweight but not stunting. To build on the existing literature base for GBD on risk-outcome pairs, a literature search was conducted for GBD 2017 searching for case-control studies published after January 1st, 1985; this search did not return any sources that were appropriate for this work.

Table 1: Adjusted RRs for each risk-outcome pair for child growth failure

Outcome	Stunting	Wasting	Underweight
Diarrhea	<-1: 1.111 (1.023-1.273) <-2: 1.222 (1.067-1.5) <-3: 1.851 (1.28-2.699)	<-1: 6.601 (2.158-11.243) <-2: 23.261 (9.02-35.845) <-3: 105.759 (42.198-157.813)	<-1: 1.088 (1.046-1.134) <-2: 1.23 (1.163-1.314) <-3: 2.332 (2.076-2.802)
Lower respiratory infections (LRI)	<-1: 1.125 (0.998-1.655) <-2: 1.318 (1.014-2.165) <-3: 2.355 (1.15-5.114)	<-1: 5.941 (1.972-11.992) <-2: 20.455 (70.84-37.929) <-3: 47.67 (15.923-94.874)	<-1: 1.145 (1.044-1.364) <-2: 1.365 (1.215-1.755) <-3: 2.593 (1.908-4.39)

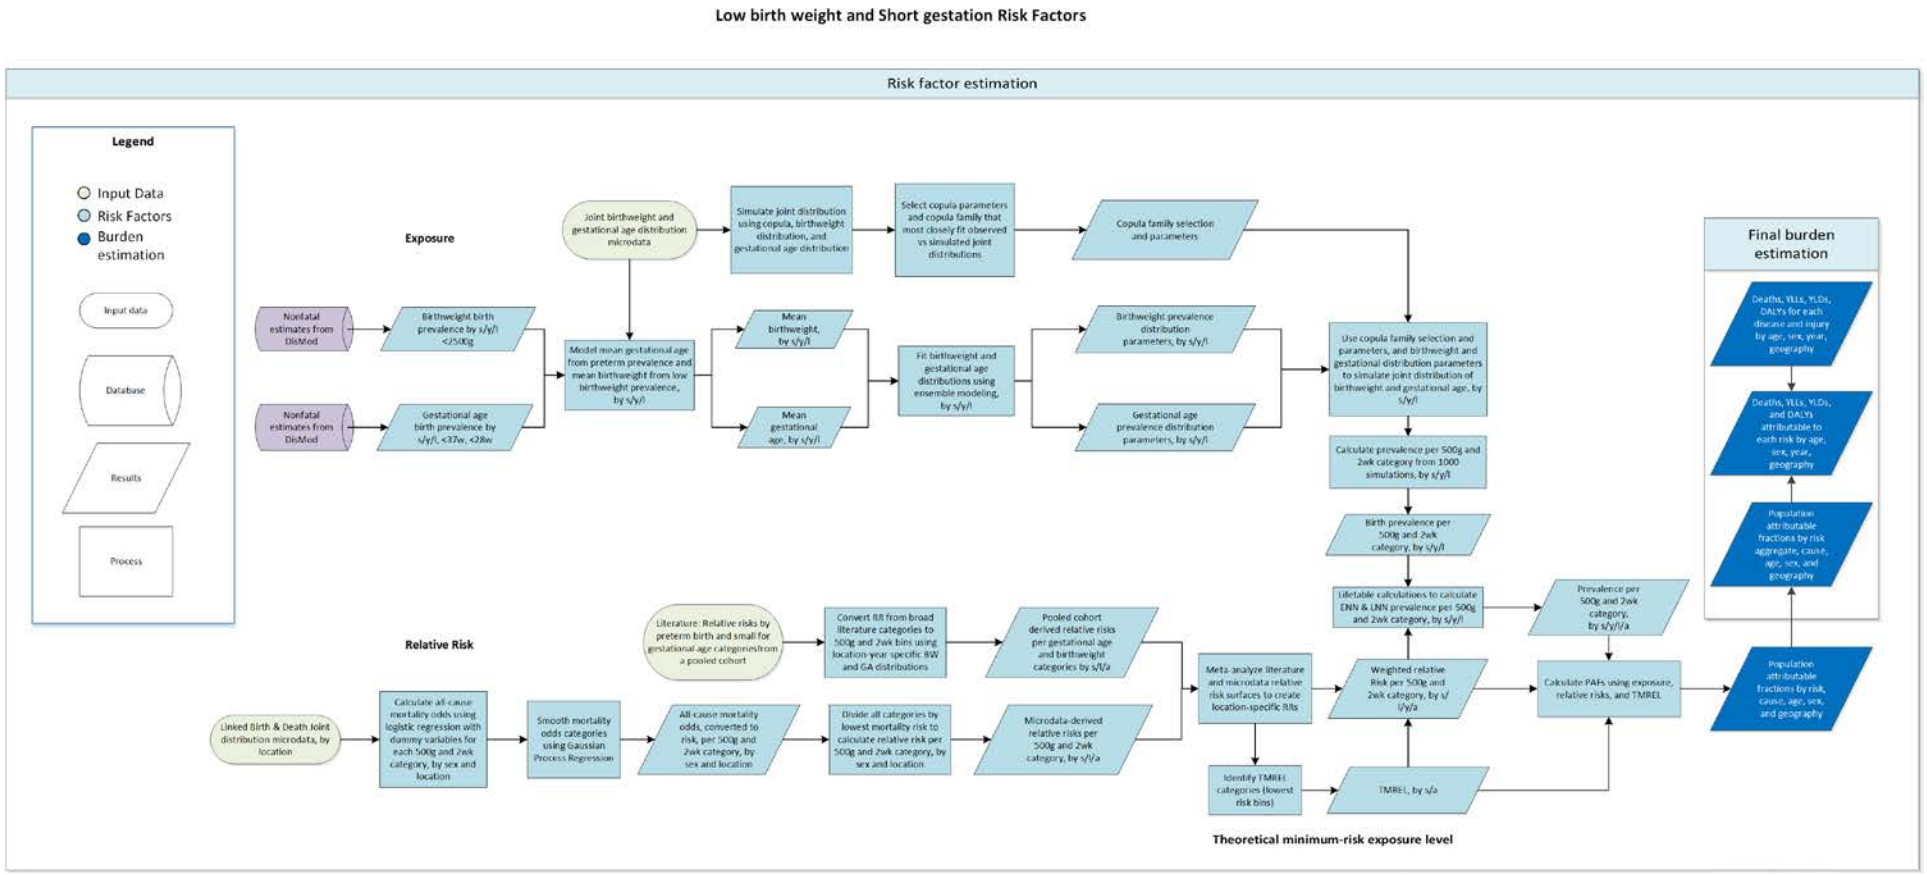
Low Birth Weight and Short Gestation Capstone Appendix

Flowchart



Input data and methodological summary

The “Low Birth Weight and Short Gestation” (LBWSG) risk factor and its child risks “Low Birth Weight for Gestation” and “Short Gestation for Birth Weight” first were included as risk factors in GBD 2016.

Although low birth weight for gestation and short gestation for birth weight are separate risk factors, the exposures and relative risks for both are estimated jointly through the low birth weight and short gestation parent risk factor. As of GBD 2017, LBWSG are the only risk factors estimated jointly.

Case definition

The meaning of the “low birth weight” and “short gestation” in GBD have subtle definitional differences compared to other usages of “low birth weight” and “short gestation” in literature. The term “low birth weight” has historically been used to refer to birth weight (BW) less than 2500 grams. However, because the goal of the GBD risk factors analysis is to quantify the entirety of attributable burden due to each risk factor, the GBD definition of “low birth weight” therefore refers to all birth weight below the Theoretical Minimum Risk Exposure Level (TMREL) for birth weight. Likewise, new-borns have been typically been classified into gestational age (GA) categories of “extremely preterm” (<28 weeks of gestation), “very preterm” (28-<32 weeks of gestation), and “moderate to late preterm” (32-<37 weeks of gestation). “Short gestation” in GBD refers to all gestational ages below the gestational age TMREL.

Exposures and relative risks for the GBD Low birth weight and short gestation risk factors are divided into joint 500-gram birth weight and 2-week gestational age combinations. The lowest risk overall 500-gram/2-week bin is the overall TMREL. The univariate TMRELs vary with GA and BW. The lowest risk GA varies by BW category and the lowest risk BWs vary with GA category. The latter are used to quantify univariate attributable risk. Under this framework, all attributable burden under the joint TMREL is referred to jointly as burden of LBWSG. All attributable burden to BWs under the TMREL for each GA category are, on aggregate, “low birth weight” and all attributable burden to GAs under the TMREL for each BW category are, on aggregate, “short gestation.” Each combination of 500-grams and 2-wks is associated with a relative risk for mortality by neonatal period (early and late neonatal) and by the causes listed in Table 2 and described below, and relative to the joint TMREL.

Exposure

Input data

To model the joint distribution of exposure of low birth weight and short gestation for each location, year, and sex estimated in GBD 2017, three types of information are used:

- Distribution of gestational age for each location, year, and sex
- Distribution of birth weight for each location, year, and sex
- Copula family and parameters, specifying correlation between gestational age and birth weight distributions

Modelling strategy

Distributions of birth weight & gestational age

To model the joint distribution of birth weight and gestational age for every location-sex-year, ensemble model methods standard to GBD risk factors (described elsewhere in the methods appendix), are first used to create separate distributions of birth weight and gestational age for every location-sex-year.

Microdata is the most ideal data source for modelling distributions; however, microdata is not widely available for birth weight and is more scarce for gestational age. Categorical prevalence data is much more readily available, and from a wider range of locations and years, for low birth weight (<2500g), extremely preterm (<28 weeks of gestation), very preterm (28-32 weeks of gestation), moderate to late preterm (32-37 weeks of gestation), and preterm birth (<37 weeks of gestation). From GBD 2010 to GBD 2015, this categorical data has been used model birth prevalence of preterm birth by gestational age (<28 weeks, 28-<32 weeks, and 32-<37 weeks) and low birth weight (<2500g) for every location, sex, and year estimated in GBD. Starting in GBD 2016 with the introduction of the LBWSG risk factors, the full distributions at birth have been modelled for gestational age and birth weight for all GBD locations, estimation years, and both sexes. The gestational age and birth weight distributions are then aggregated into the categorical estimates of <28 weeks, 28-<32 weeks, 32-<37 weeks gestation, and <2500 g birth weight.

Ensemble model methods standard to GBD are used to model the distribution at birth of gestational age and birth weight. Gestational age ensemble distribution models use the prevalence of <37 weeks gestation, the prevalence of <28 weeks gestation, and mean gestational age per each location-year-sex as inputs into the model. Birth weight distribution models use the prevalence of <2500 grams birth weight and mean birth weight per each location-year-sex. Prevalence of <37 weeks gestation and of <2500 grams birth weight was estimated for all location-year-sexes using STGPR modelling processes standard to GBD.

Low birth weight (<2500 grams) data was extracted from literature, vital registration systems, and surveys. DHS survey data were observed to have high missingness; to correct for the missingness, birth weight was imputed using the Amelia package in R. Birth weight was predicted using standard Amelia imputation methods from the following variables also in the DHS surveys: urbanicity, sex, birthweight recorded on card, birth order, maternal education, paternal education, child age, child weight, child height, mother's age at birth, mother's weight, shared toilet facility, and household water treated. Data counts for categorical prevalence models are listed in Table 1.

Table 1: Data Counts for Categorical Prevalence Models

	<28 weeks	<37 weeks	<2500 grams
Site-years (total)	1872	2420	2980
Number of GBD regions with data (out of 21 regions)	14	21	21
Number of GBD super-regions with data (out of 7 super-regions)	6	7	7

Global ensemble weights for gestational age were derived by using a 3 million sample of all available microdata in Table 2 to select the ensemble weights. Of the exponential, gamma, inverse gamma, Weibull, log normal, and normal distributions, the three distribution families that received the highest weights were the Weibull (87%), normal (4%), and inverse gamma (4%) distributions. Global ensemble weights for birth weight were derived using a 3 million sample of all available microdata in Table 2, in addition to birth weight microdata available primarily through the DHS and MICS surveys. Of the exponential, gamma, inverse gamma, Weibull, log normal, and normal distributions, the three

distribution families that received the highest weights were the log normal (38%), normal (32%), and Weibull (20%) distributions.

Ordinary least squares was used to model mean gestational age for all location-year-sexes by regressing mean gestational age on prevalence of <37 weeks gestation per location-year. All available microdata (Table 2) was used to fit the model. OLS was also used to model mean birth weight by regressing prevalence of <2500 g birth weight per location-year. All available joint microdata (Table 2), as well as additional birth weight microdata extracted primarily through DHS and MICS surveys, was used to fit the model. As estimates of prevalence of <37 weeks gestation and prevalence of <2500g birth weight are available for all location-year-sexes through STGPR models, mean gestational age and mean birth weight were predicted for all location-year-sexes.

Copula optimisation

In order to model the joint distribution of gestational age and birth weight from separate distributions, information is needed about the correlation between the two distributions. Distributions of gestational age and birth weight are not independent; the Spearman correlation for each country where joint microdata was available (Table 2), pooling across all years of data available, ranged from 0.25-0.49. The overall Spearman correlation was 0.38, pooling across all countries in the dataset.

Table 3: Summary of Data Inputs

Location	Years of data	Total births*	Format of data	Spearman correlation	Used in Ensemble Weight Selection	Used in Copula Parameter Selection	Used in Relative Risk Models
BRA	2016	2,854,380	Microdata	0.37	Yes	Yes	No

** Pooled across all year and sexes, excluding data missing year of birth, gestational age, or birth weight*

Copula modelling is used to model joint distributions between the birth weight and gestational age marginal distributions. The Copula and VineCopula packages in R were used to select the optimal copula family and copula parameters to model the joint distribution, using joint microdata from the country-years in Table 2. The copula family selected from the microdata was “Survival BB8”, with theta parameter set to 1.75 and delta parameter set to 1.

The joint distribution of birth weight and gestational age per location-year-sex was modelled using the global copula family and parameters selected and the location-year-sex gestational age and birth weight distributions. The joint distribution was simulated 100 times to capture uncertainty. Each simulation consisted of 100,000 simulated joint birth weight and gestational age data points. Each joint distribution

was divided into 500g by 2wk bins to match the categorical bins of the relative risk surface. Birth prevalence was then calculated for each 500g by 2wk bin.

Estimating Early Neonatal Prevalence & Late Neonatal Prevalence from Birth Cohorts

Early neonatal prevalence and late neonatal prevalence was estimated using life table approaches for each 500g & 2wk bin. Using the all-cause early neonatal mortality rate for each location-year-sex, births per location-year-sex-bin, and the relative risks for each location-year-sex-bin in the early neonatal period, the all-cause early neonatal mortality rate was calculated for each location-year-sex-*bin*. The early neonatal mortality rate per bin was used to calculate the number of survivors at 7 days and prevalence in the early neonatal period. Using the same process, the all-cause late neonatal mortality rate for each location-year-sex was paired with the number of survivors at 7 days and late neonatal relative risks per bin to calculate late neonatal prevalence and survivors at 28 days.

Relative risks & theoretical minimum-risk exposure level

Causes

The available data for deriving relative risk was only for all-cause mortality. The exception was the USA linked infant birth-death cohort data, which contained 3-digit ICD causes of death, but also had nearly 30% of deaths coded to causes that are ill-defined, or intermediate, in the GBD cause classification system. For GBD 2017, like in GBD 2016, we analysed the relative risk of all-cause mortality across all available sources and selected outcomes based on criteria of biologic plausibility. Some causes, most notably congenital birth defects, haemoglobinopathies, malaria, and HIV/AIDS, were excluded based on the criteria that reverse causality could not be excluded. The final list of outcomes included in calculating the attributable burden for LBW/SG are in Table 3.

Table 3: Cause list of outcomes for low birth weight and short gestation

Cause ID	**Cause name**
302	Diarrheal diseases
322	Lower respiratory infections
328	Upper respiratory infections
329	Otitis media
333	Pneumococcal meningitis
334	H influenzae type B meningitis
335	Meningococcal meningitis
336	Other meningitis
337	Encephalitis
381	Neonatal preterm birth complications
382	Neonatal encephalopathy due to birth asphyxia and trauma
383	Neonatal sepsis and other neonatal infections
384	Hemolytic disease and other neonatal jaundice
385	Other neonatal disorders
686	Sudden infant death syndrome

Input data

In the Norway, New Zealand, and US Linked Birth/Death Cohort microdata datasets, live births are reported with gestational age, birth weight, and an indicator of death at 7 days and 28 days. For this analysis, gestational age was grouped into two-week categories, and birth weight was grouped into 500-gram categories. The Taiwan, Japan, and Singapore datasets were prepared in tabulations of joint 500-gram and two-week categories.

Modelling strategy

For each location, data was pooled across years, and the risk of all-cause mortality at the early neonatal period and late neonatal period at joint birth weight and gestational age combinations was calculated. In all datasets except for the United States, sex-specific data were combined to maximise sample size. The United States analyses were sex-specific. To calculate relative risk at each 500g and 2wk combination, logistic regression was first used to calculate mortality odds for each joint 2-week gestational age and 500-gram birth weight category. Mortality odds were smoothed with Gaussian Process Regression, with the independent distributions of mortality odds by birth weight and mortality odds by gestational age serving as priors in the regression.

A pooled country analysis[1] of mortality risk in the early neonatal period and late neonatal period by SGA category in developing countries in Asia and Sub-Saharan Africa were also converted into 500-gram and 2-week bin mortality odds surfaces. The relative risk surfaces produced from microdata and the Asia and Africa surfaces produced from the pooled country analysis were meta-analyzed, resulting in a meta-analysed mortality odds surface for each location. The meta-analysed mortality odds surface for each location was smoothed using Gaussian Process Regression and then converted into mortality risk. To calculate mortality relative risks, the risk of each joint 2-week gestational age and 500-gram birth weight category were divided by the risk of mortality in the joint gestational age and birth weight category with the lowest mortality risk.

For each of the country-derived relative risk surfaces, the 500 g and 2-week gestational age joint bin with the lowest risk was identified. This bin differed within each country dataset. To identify the universal 500 g and 2-week gestational age category that would serve as the universal TMREL for our analysis, we chose the bins that was identified to be the TMREL in each country dataset to contribute to the universal TMREL. Therefore, the joint categories that served as our universal TMREL for the LBWSG risk factor were “38-40 weeks of gestation and 3500-4000 grams", "38-40 weeks of gestation and 4000-4500 grams", and "40-42 weeks of gestation and 4000-4500 grams". As the joint TMREL, all three categories were assigned to a relative risk equal to 1.

PAF calculations

The total PAF for the low birth weight and short gestation joint risk factor is calculated by summing the PAF calculated from each 500g x 2wk category, with the lowest risk category among all the 500g x 2wk categories serving as the TMREL. The equation for calculating PAF for each 500g x 2wk category is:

$$PAF_{joasgt} = \frac{\sum_{x=1}^{u} RR_{joast}(x)P_{jasgt}(x) - RR_{joasg}(TMRE_{jas})}{\sum_{x=1}^{u} RR_{joas}(x)P_{jasgt}(x)}$$

To calculate the overall PAF for the short gestation for birth weight risk factor, PAF was once again calculated for each joint 500-gram and 2-week category. Unlike the joint PAF calculation, which used only one TMREL for all 500-gram and 2-week categories, the joint 500-gram and 2-week category with the lowest risk for each 500-gram birth weight grouping served as the TMREL for that 500-gram birth weight grouping. For example, the [3000, 3500) gram birth weight grouping contains five joint categories: [34, 36) weeks and [3000, 3500) grams; [36, 37) weeks and [3000, 3500) grams; [37, 38) weeks and [3000, 3500) grams; [38, 40) weeks and [3000, 3500) grams; and [40, 42) weeks and [3000, 3500) grams. The [40, 42) weeks and [3000, 3500) grams joint category has the lowest risk, and so it serves as the TMREL for the [3000, 3500) gram birth weight grouping. In the Relative Risk surface figures, a birth weight grouping is one "column" of the birth weight and gestational age matrix.

The overall PAF for the short gestation for birth weight risk factor was then calculated for all the joint 500-gram and 2-week categories using the formula below:

$$PAF_{1..i} = 1 - \prod_{i=1}^{n}(1 - PAF_i)$$

The same methodology was applied to calculate the total PAF for the low birth weight for gestation risk factor, using two-week gestational age categories (each "row" of the matrix) instead of 500-gram birth weight categories. For example, the [24, 26) weeks gestational age grouping contains three joint categories: [0, 500) grams and [24, 26) weeks; [500, 1000) grams and [24, 26) weeks; and [1000, 1500) grams and [24, 26) weeks. The [1000, 1500) grams and [24, 26) weeks joint category has the lowest risk, and so it serves as the TMREL for the [24, 26) weeks gestational age grouping.

After the short gestation for birth weight PAF and low birth weight for gestational age PAF were calculated, they were then scaled so that the sum of the short gestation for birth weight PAF and low birth weight for gestation PAF equal the low birth weight and short gestation parent PAF calculated for each location/year/sex/age group.

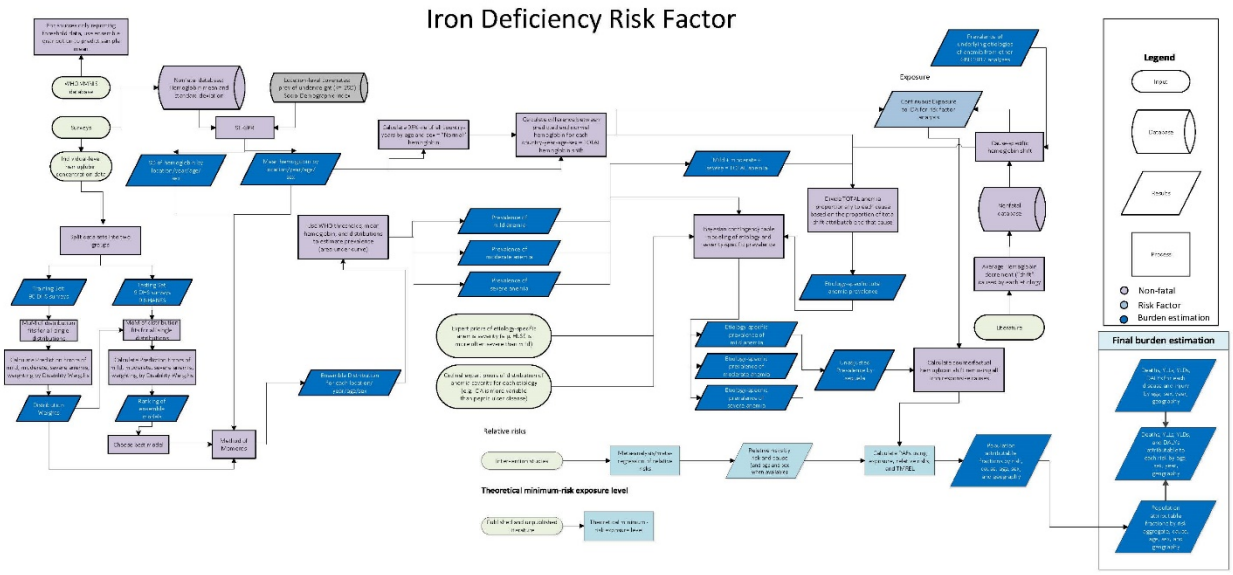
Iron Deficiency Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

For GBD 2017, as with GBD 2016, the anemia model has two main steps: estimation of the anemia envelope and causal attribution. Our analytic strategy began with calculation of an anemia envelope – a determination of mean hemoglobin, as well as a sum total of anemia prevalence, by severity for each country, age group, and both sexes for each year from 1990 through 2017. The envelope approach avoids double-counting while capturing potentially different disease profiles within each population group. We defined a population group as a specific geography, sex, age-group, and year.

Input data

Iron-deficiency anemia (IDA) estimates include acute and chronic hemorrhagic states for which supplementation may be helpful, but poor nutritional intake is not the only underlying problem. A few causes in this category – hookworm, schistosomiasis, upper gastrointestinal bleeding, and gynecologic diseases – were considered separately from IDA in GBD 2016 because there was enough data from GBD prevalence estimation processes to do so. Distribution of anemia burden to IDA only after assignment to "known" causes avoided double counting of these cases. In GBD 2017, we redefined the iron deficiency risk factor to encompass all causes of anemia that would respond to iron supplementation.

For our nonfatal anemia estimates, the envelope approach to the anemia impairment utilises data from a variety of sources. Population-based surveys of hemoglobin concentration were the primary input to our analytic dataset. Examples include the Demographic and Health Survey (DHS) and Multiple Indicator Cluster Survey (MICS) series, along with other national and subnational surveys that completed hemoglobin testing. We supplemented with pertinent sources downloaded from the WHO Vitamin and

Mineral Nutrition Information System (VMNIS) available at http://www.who.int/vmnis/database/anaemia/countries/en/. A full source list is available elsewhere in this appendix. Most used a HemoCue test, adjusted for altitude, and excluded those with terminal or acute medical conditions. Inclusion, exclusion and diagnostic criteria for other studies were similar and can be found in each study.

Modelling strategy

For GBD 2017, we estimated the mean hemoglobin in g/dL among pregnant women aged 15 to 49 years of age and the implied mean hemoglobin among pregnant women in the absence of iron deficiency anemia, as the risk exposure for maternal iron deficiency anemia.

Theoretical minimum-risk exposure level

The implied mean hemoglobin in the absence of iron deficiency anemia is the theoretical minimum risk exposure level. This was calculated by adding the iron responsive hemoglobin shift back onto the observed hemoglobin concentration for each demographic. For example, if the observed hemoglobin concentration among 30-34 year old pregnant women in Ethiopia was 132.9 g/L, and the shift was 1.6 g/L in that demographic, then the counterfactual was 134.5 g/L. The GBD 2017 anemia modelling strategy provides details on how the iron deficiency shifts were calculated.

Relative risk

We attribute 100% of iron-deficiency anemia to iron deficiency. The other outcomes used in GBD 2016 are maternal hemorrhage, maternal sepsis and other maternal infections. In GBD 2017 we added the following additional maternal outcomes: maternal hypertensive disorders, maternal obstructed labor an uterine rupture, maternal abortion and miscarriage, ectopic pregnancy, indirect maternal deaths, late maternal deaths, maternal deaths aggravated by HIV/AIDS, and other maternal disorders. For these additional maternal outcomes, we assigned the same relative risk as that used for the maternal outcomes from 2016. Sources of evidence for these relative risks are unchanged from GBD 2013.

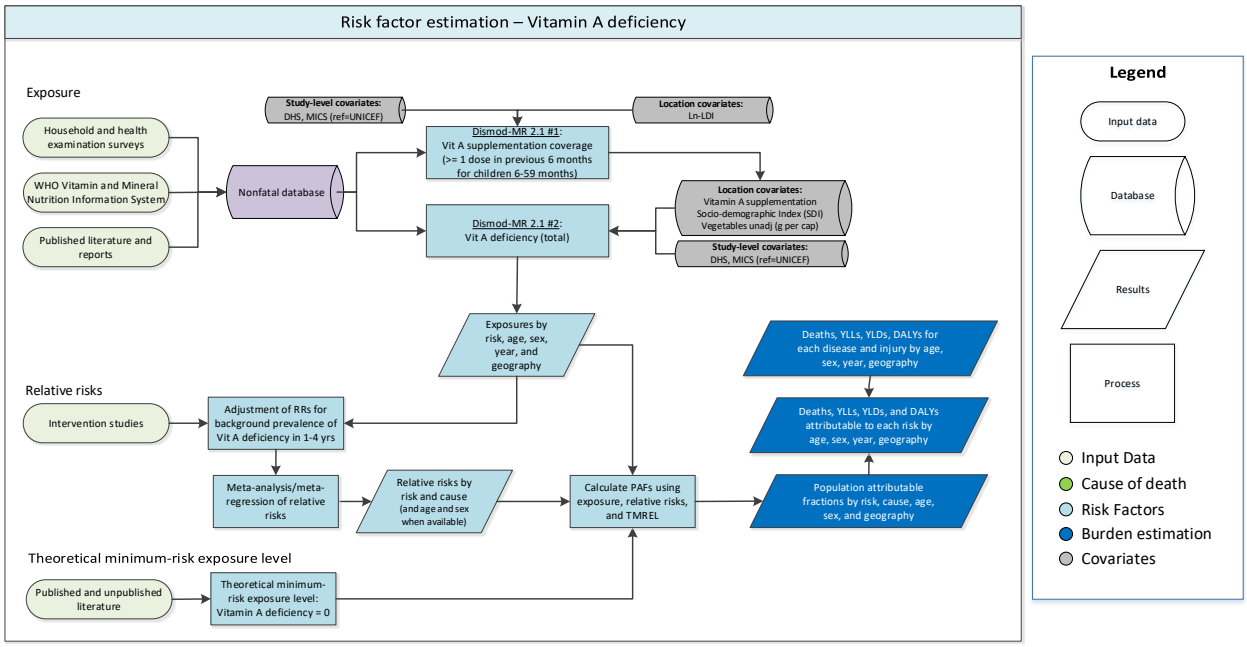
Vitamin A Deficiency Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

For GBD 2017, vitamin A deficiency is defined as serum retinol <70 µmol/L. We examined vitamin A deficiency as a risk factor in children aged 6 months to 5 years.

To ensure we were using as much information as possible, and therefore maximize the data basis of our estimates, we modeled Vitamin A deficiency sequentially. The first step was to estimate the coverage of Vitamin A supplementation. Although the typical metric on which supplementation is tracked is 2+ doses of Vitamin A in the previous 12 months for children under 5 years, most existing health surveys do not routinely provide sufficient information to calculate it. Our case definition for the supplementation model was therefore the proportion of children 6-59 months of age who received at least one dose of Vitamin A in the previous 6 months. Supplementation estimates were then used as a location-level covariate to guide exposure models of overall Vitamin A deficiency.

Input data

For GBD 2017, we used data from the WHO Vitamin and Mineral Nutrition Information System, health surveys such as DHS and MICS, and studies identified through literature review. This included updating the dataset to include all ages and all studies available in VMNIS as of April 2018. A separate systematic review was last conducted for GBD 2013. The PubMed search terms were: ((vitamin A deficiency[Title/Abstract] AND prevalence[Title/Abstract]) AND ("2009"[Date – Publication] : "2013"[Date – Publication])). The table below shows the number of data points included in the final datasets**.** Exclusion criteria were:

1. Studies that were not population-based, e.g., hospital or clinic-based studies
2. Studies that did not provide primary data on epidemiological parameters, e.g., commentaries
3. Review articles
4. Case series
5. Self-reported cases

Table 1. Geographic representation of datasets used for three stages of Vitamin A deficiency risk factor burden estimation (number of data points per geography)

Geography	Supplementation (proportion)	Deficiency (prevalence)
Global	900	1540
East Asia	12	27
Southeast Asia	102	212
Oceania	24	54
Central Asia	51	66
Central Europe	2	13
Eastern Europe		3
Australasia		1
Western Europe		38
Southern Latin America		16
High-income North America		33
Caribbean	17	34
Andean Latin America	25	70
Central Latin America	33	212
Tropical Latin America	1	52
North Africa and Middle East	49	148
South Asia	61	96
Central Sub-Saharan Africa	60	8
Eastern Sub-Saharan Africa	182	220
Southern Sub-Saharan Africa	49	57
Western Sub-Saharan Africa	232	180

Modeling strategy

All Vitamin A deficiency estimates were made using DisMod-MR 2.1. As described above, we first estimated Vitamin A supplementation coverage. Although all data was from ages 6-59 months, we assumed no difference in age pattern of supplementation coverage and used the natural log of lag-distributed income per capita (LN-LDI) as a location-level covariate to inform estimates where data was absent. DHS and MICS data was cross-walked to the reference data source, which came from UNICEF (http://data.worldbank.org/indicator/SN.ITK.VITA.ZS).

Table 2: Covariate effects for Vitamin A supplementation model

Measure	Covariate	Type	Value	Exponentiated
Prevalence	MICS	Study-level	-0.6 (-0.76 — -0.45)	0.55 (0.47 — 0.64)
Prevalence	DHS	Study-level	-0.09 (-0.2 — 0.025)	0.91 (0.82 — 1.03)
Prevalence	LDI (I$ per capita)	Country-level	0.013 (0.00033 — 0.042)	1.01 (1.00 — 1.04)

Second, we estimated the age- and sex-specific prevalence of Vitamin A deficiency (serum retinol < 0.7 µmol/L). WHO VMNIS was the primary data source for this model and was supplemented with data from DHS and other health surveys where testing was performed. We assumed the following in our model: no excess mortality, birth prevalence is possible, incidence is decreasing after age 5 and remission is increasing after age 5. Data from subnational locations was crosswalked to the reference data sources of nationally-representative data. Females were found to have 1.09 times higher Vitamin A deficiency, although the uncertainty in that ratio ranged from 0.97 to 1.24. Location-level covariates were used for Vitamin A supplementation coverage from the above model as well as GBD 2016 Socio-demographic Index (SDI) numbers.

Table 3: Covariate effects for Vitamin A deficiency model

Measure	Covariate	Type	Value	Exponentiated
Prevalence	Sex	Study-level (x-cov)	-0.0091 (-0.088 — 0.065)	0.99 (0.92 — 1.07)
Prevalence	Subnational	Study-level (x-cov)	-0.28 (-0.44 — -0.1)	0.76 (0.64 — 0.90)
Prevalence	Vitamin A supplem. coverage rate	Country-level	-0.028 (-0.1 — -0.00071)	0.97 (0.90 — 1.00)
Prevalence	Socio-demographic Index	Country-level	-2.98 (-3 — -2.92)	0.051 (0.050 — 0.054)
Prevalence	vegetables unadjusted(g)	Country-level	-1.36 (-1.53 — -1.12)	0.26 (0.22 — 0.33)

Theoretical minimum-risk exposure level

The theoretical minimum risk exposure is that the prevalence of vitamin A deficiency is zero.

Relative risks

The relative risks were updated in GBD 2017 to reflect studies included in the most recently published systematic review by Imdad and colleagues.[1] The overall estimation strategy has not changed. For each trial identified by the systematic review, we adjusted the relative risk for the background prevalence of Vitamin A deficiency in 1-4 years from the GBD 2017 model described above. This adjustment assumes the effect of supplementation is observed only in the fraction of the trial population that are Vitamin A deficient. Many studies evaluate either incidence or mortality. A subset of studies evaluated both incidence and cause-specific mortality as outcomes for the same cause. We found no statistical difference between the effect sizes of incidence and mortality in any of these studies so pooled all incidence and mortality observations as independent observations prior to meta-analysis. We then performed a fixed effects meta-analysis of all adjusted RRs to determine final outcomes to be included in GBD risk factor attribution estimates. Forest plots are shown in Figures 1-5; Final RRs are shown in Table 4. Three outcomes – diarrhea, lower respiratory infections (LRI), and measles – were found to be statistically significant after adjustment, pooling, and meta-analysis. Meningitis was non-significant. Malaria was significant, but only a single study was identified that evaluated this outcomes, which does not meet GBD causal criteria.

Table 4: Pooled relative risks for risk-outcome pairs included in GBD 2017

Cause	GBD 2016 RR	GBD 2017 RR	Include in GBD 2017
Diarrhea	1.6 (1.21 - 2.02)	**2.35 (2.17 - 2.54)**	Yes
Measles	2.4 (1.61 - 3.48)	**2.76 (2.01 - 3.78)**	Yes
Lower Respiratory Infections (LRI)		**1.23 (1.03 - 1.48)**	Yes
Meningitis		3.2 (0.69 - 14.75)	No (not significant)
Malaria		3.65 (2.23 - 5.97)	No (only one study)

Figure 1: Forest plot of RR of diarrhea in Vitamin A deficiency

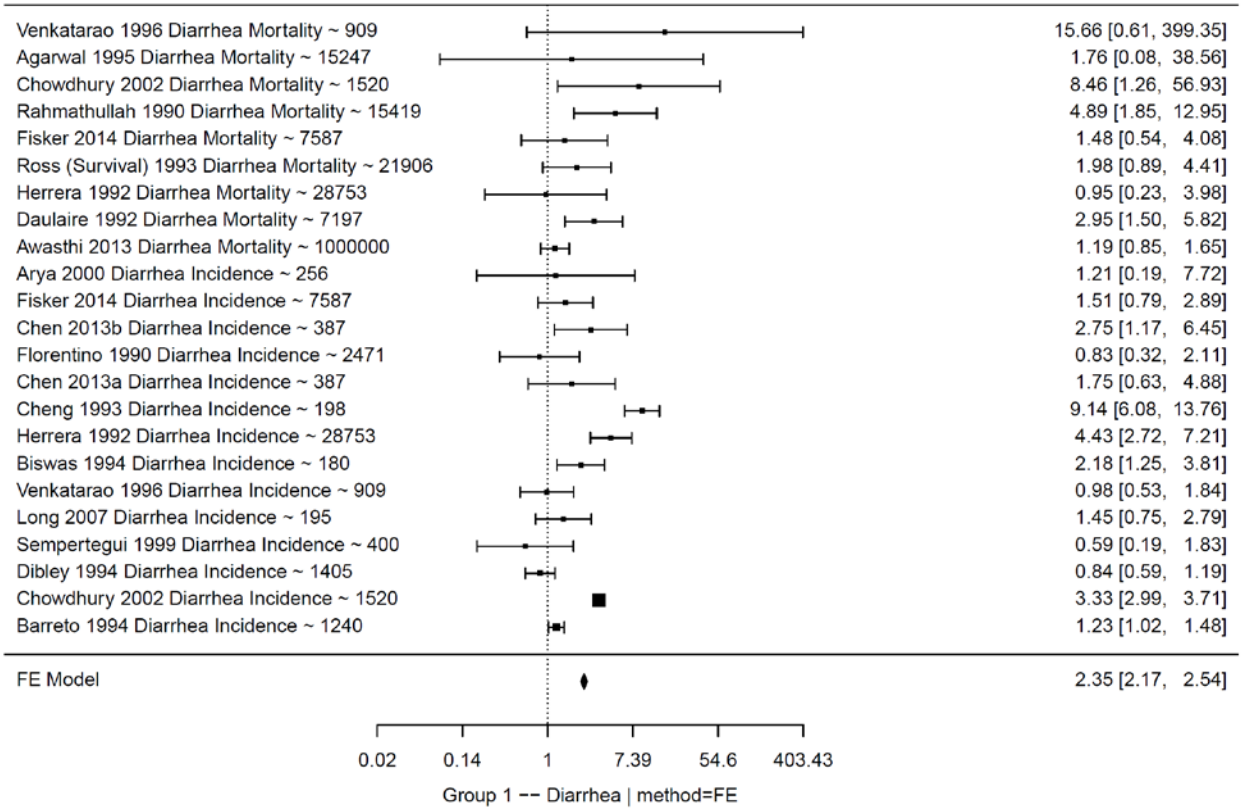


Figure 2: Forest plot of RR of measles in Vitamin A deficiency

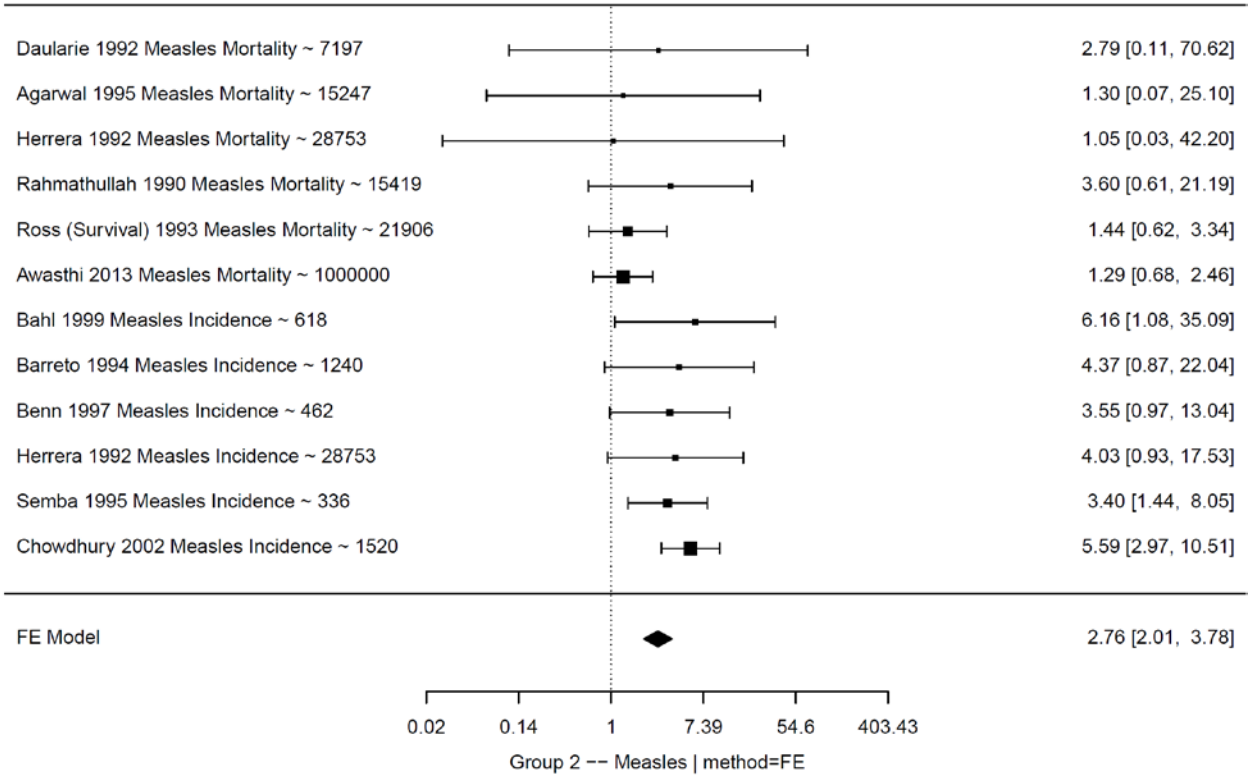

Figure 3: Forest plot of RR of LRI in Vitamin A deficiency

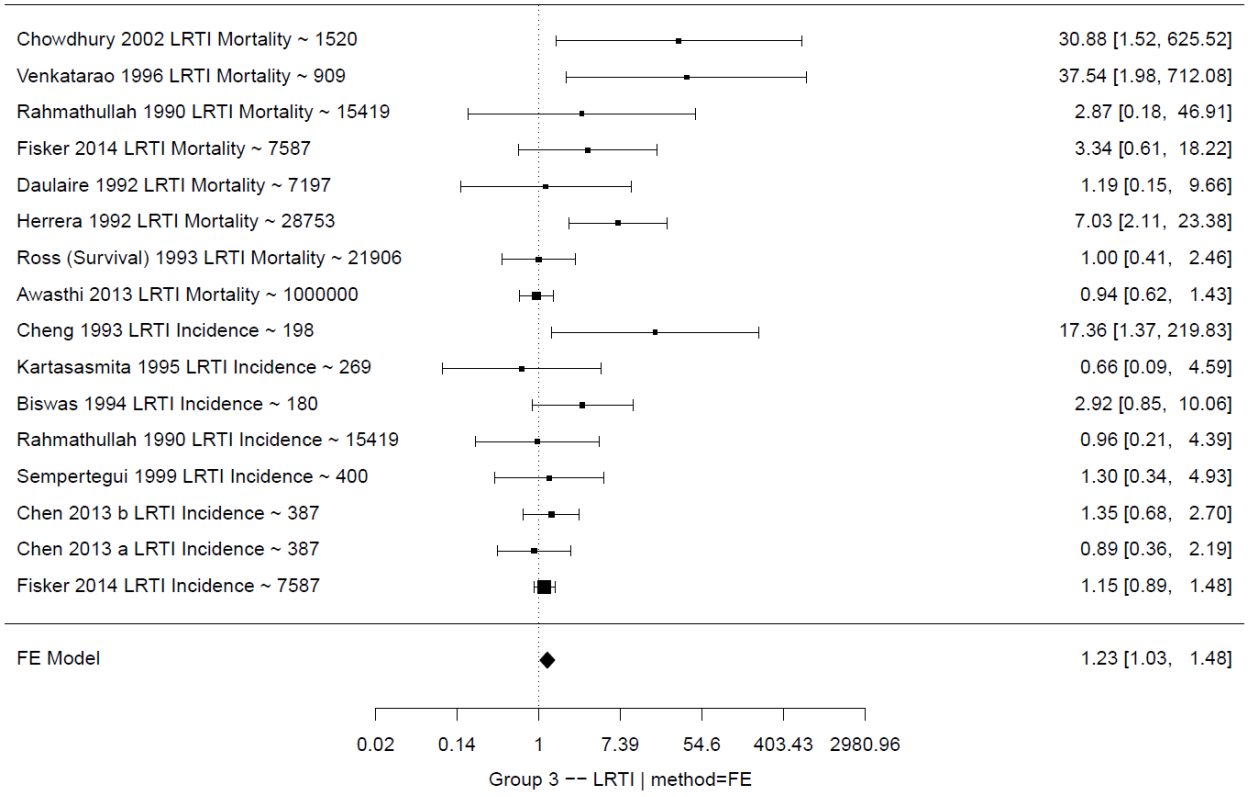

Figure 4: Forest plot of RR of meningitis in Vitamin A deficiency

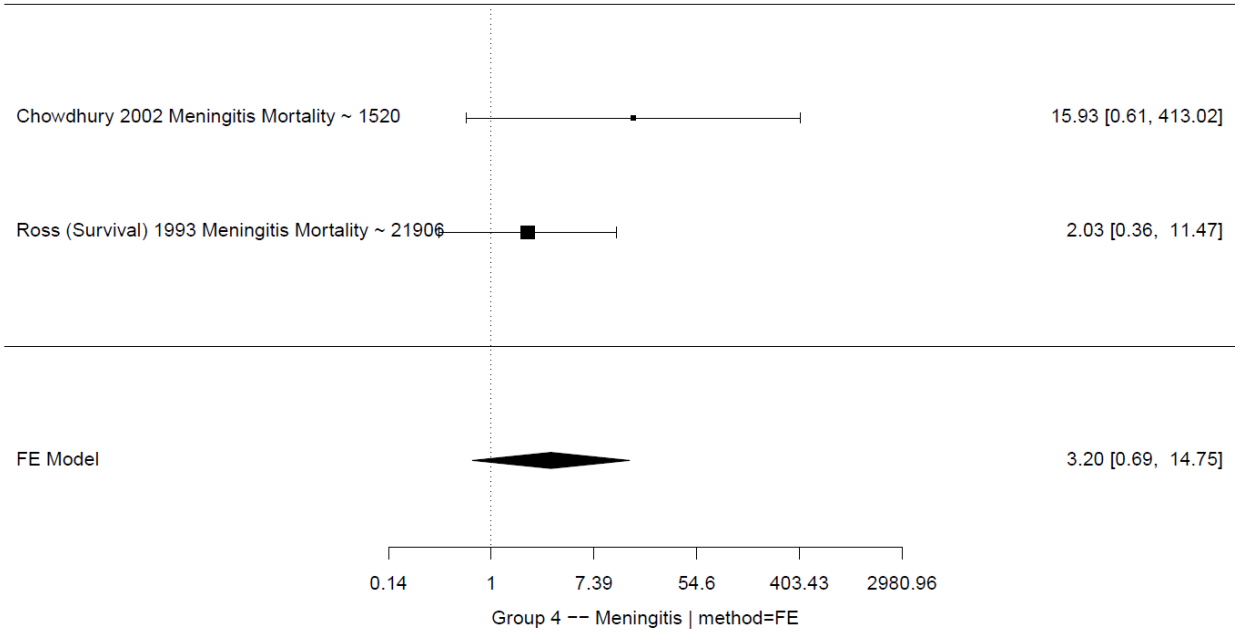

Figure 5: Forest plot of RR of malaria in Vitamin A deficiency

Zinc Deficiency Capstone Appendix

Input data & methodological summary

Exposure

Case definition

Exposure to zinc deficiency is defined as consumption of less than 2.5 milligrams of zinc per day among children between the ages of 1 and 4 years old.

Input data

We used dietary data from nationally and sub-nationally representative nutrition surveys and United Nations FAO Supply and Utilization Accounts to estimate the mean intake of zinc at the population level.

Modelling strategy

For GBD 2016, we first used a spatio-temporal Gaussian process regression (ST-GPR) framework to estimate the mean intake of zinc by age, sex, country, and year. To assist with estimation for locations and years without data, we used the lag-distributed income of that location-year as a covariate. We considered data from 24-hour diet recall as the gold standard, and adjusted data from other sources to the gold standard method. Using the method described in the dietary risks section, we characterised the distribution of zinc intake for children between ages of 1 and 4 years old and estimate the proportion of the children with intake of less than 2.5 milligrams of zinc per day.

Relative risk

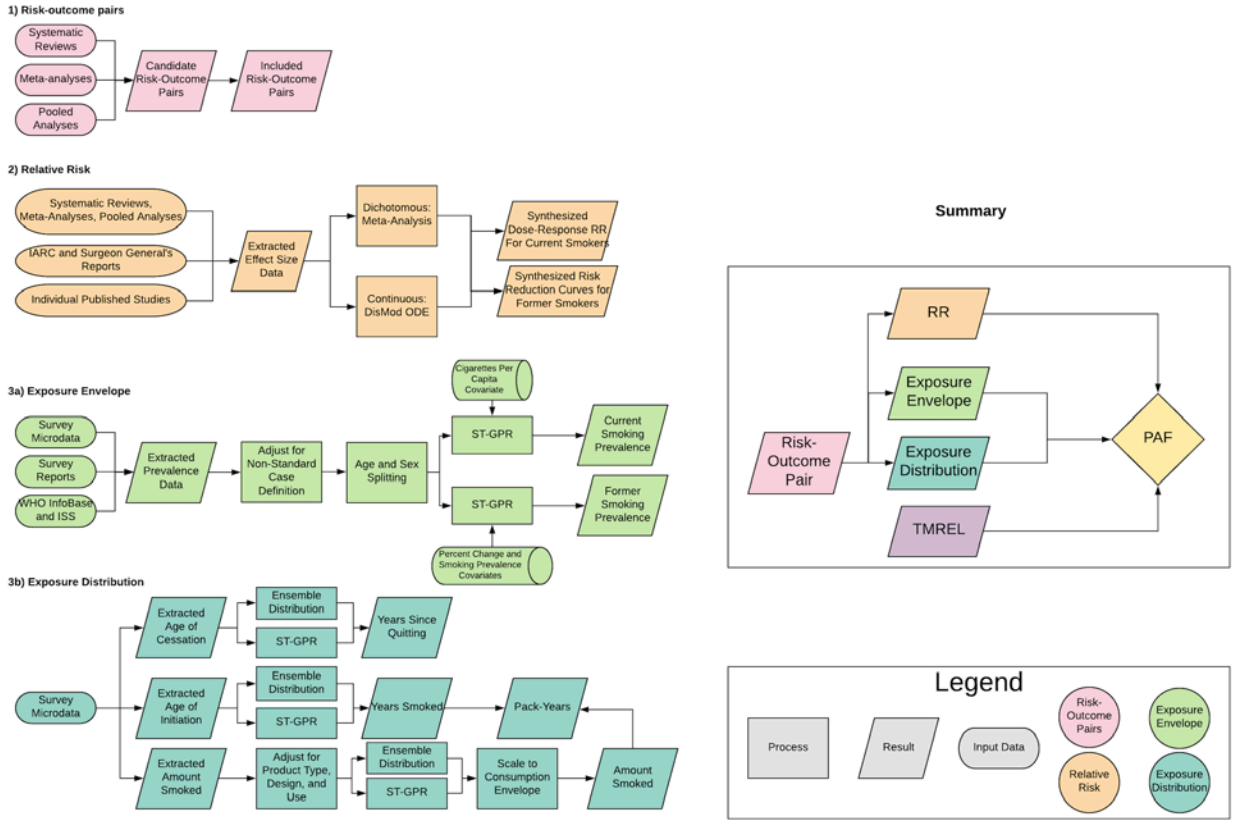
Relative risks used for zinc deficiency is based on the results of randomised trials that measured the effect of zinc supplementation.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for proportion zinc deficient is zero percent deficient.

Smoking Capstone Appendix

Flowchart



We made significant changes to the methods used to estimate smoking attributable burden in GBD 2017. In previous iterations of the GBD, we have used the Peto-Lopez (Smoking Impact Ratio) method to estimate burden attributable to cancers and chronic respiratory diseases. Although this method provides robust estimates of the burden of cancers and chronic respiratory diseases related to tobacco, it is not fully consistent with the GBD approach of estimating exposure independently of the outcomes affected by exposure. For cardiovascular diseases and all other smoking attributable health outcomes, we used five-year lagged daily smoking prevalence as the exposure. With a growing body of evidence on the association between smoking and several types of cancers and with cardiovascular disease, coupled with good estimates of the distribution of cumulative smoking exposure, direct estimation of attributable burden is possible. In GBD 2017, we have transitioned to using continuous measures of exposure that incorporate dose-response effects among daily, occasional, and former smokers for all health outcomes except fractures.

Current and former smoking prevalence

We estimated the prevalence of current smoking and the prevalence of former smoking using data from cross-sectional nationally representative household surveys. We defined current smokers as individuals who currently use any smoked tobacco product on a daily or occasional basis. We defined former

smokers as individuals who quit using all smoked tobacco products for at least 6 months, where possible, or according to the definition used by the survey. Prior to modelling a complete time series for all demographic groups, we made adjustments for alternative case definitions as well as for data reported in non-standard age or sex groups. We modelled current and former prevalence using spatiotemporal Gaussian process regression.

Data extraction

We extracted primary data from individual-level microdata and survey report tabulations. We extracted data on current, former, and/or ever smoked tobacco use reported as any combination of frequency of use (daily, occasional, and unspecified, which includes both daily and occasional smokers) and type of smoked tobacco used (all smoked tobacco, cigarettes, hookah, and other smoked tobacco products such as cigars or pipes), resulting in 36 possible combinations. Other variants of tobacco products, for example hand-rolled cigarettes, were grouped into the four type categories listed above based on product similarities. Only smoked tobacco products are included, smoked drugs are estimated separately as part of the drug use risk factor.

For microdata, we extracted relevant demographic information, including age, sex, location, and year, as well as survey metadata, including survey weights, primary sampling units, and strata. This information allowed us to tabulate individual-level data in the standard GBD five-year age-sex groups and produce accurate estimates of uncertainty. For survey report tabulations, we extracted data at the most granular age-sex group provided.

Crosswalk

Our GBD smoking case definitions were current smoking of any tobacco product and former smoking of any tobacco product. All other data points were adjusted to be consistent with either of these definitions. Some sources contained information on more than one case definition and these sources were used to develop the adjustment coefficient to transform alternative case definitions to the GBD case definition. The adjustment coefficient was the beta value derived from a linear model with one predictor and no intercept.

We generated separate crosswalk coefficients for the 10-14 age group and the 15-19 age group, as we found the relationships between case definitions differed strongly in the younger age groups compared to the 20+ age groups. To account for this, we attempted to generate a global crosswalk coefficient for both the 10-14 and 15-19 age groups, using the same regression as above. Due to data limitations, none of the crosswalk coefficients met the criteria outlined above, so no data covering youths under 20 years old were crosswalked. In other words, all data from these age groups that appear in the model were asked according to our case definition in the survey.

We propagated uncertainty at the survey level from the crosswalk by incorporating both the variance of the errors and the variance of the adjustment coefficients.

For each source that needed adjusting, we assigned space weights based on GBD region and super region to the sources containing more than one case definition. Data from the same region receiving a full weight of 1, and data from the same super-region received a weight of ½. We explored using a time weight, to control for possible changes in the relationship between smokeless tobacco use behaviours over time. We found incorporating temporal information did not significantly change the estimated

coefficients but did undercut sample sizes, and chose to exclude the time weight. Crosswalk coefficients generated from fewer than 20 data sources were dropped

Age and sex splitting

We split data reported in broader age groups than the GBD 5-year age groups or as both sexes combined by adapting the method reported in Ng et al. (http://jamanetwork.com/journals/jama/fullarticle/1812960) to split using a sex- geography- time specific reference age pattern. We separated the data into two sets: a training dataset, with data already falling into GBD sex-specific 5-year age groups, and a split dataset, which reported data in aggregated age or sex groups. We then used spatiotemporal Gaussian Process Regression (ST-GPR) to estimate sex-geography-time specific age patterns using data in the training dataset. The estimated age patterns were used to split each source in the split dataset.

The ST-GPR model used to estimate the age patterns for age-sex splitting used an age weight parameter value that minimises the effect of any age smoothing. This parameter choice allows the estimated age pattern to be driven by data, rather than being enforced by any smoothing parameters of the model. Because these age-sex split data points will be incorporated in the final ST-GPR exposure model, we do not want to doubly enforce a modelled age pattern for a given sex-location-year on a given aggregate data point.

Smoking prevalence modelling

We used ST-GPR to model current and former smoking prevalence. Full details on the ST-GPR method are reported elsewhere in the Appendix. Briefly, the mean function input to GPR is a complete time series of estimates generated from a mixed effects hierarchical linear model plus weighted residuals smoothed across time, space and age. The linear model formula for current smoking, fit separately by sex using restricted maximum likelihood in R, is:

$$logit(p_{g,a,t}) = \beta_0 + \beta_1 CPC_{g,t} + \sum_{k=2}^{19} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_g + \epsilon_{g,a,t}$$

Where $CPC_{g,t}$ is the tobacco consumption covariate by geography g and time t, described above, $I_{A[a]}$ is a dummy variable indicating specific age group A that the prevalence point $p_{g,a,t}$ captures, and α_s, α_r, and α_g are super region, region, and geography random intercepts, respectively. Random effects were used in model fitting but not in prediction.

The linear model formula for former smoking is:

$$logit(p_{g,a,t}) = \beta_0 + \beta_1 PctChange_{A[a],g,t} + \beta_3 CSP_{A[a],g,t} + \sum_{k=3}^{20} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_g + \epsilon_{g,a,t}$$

Where $PctChange_{A[a],g,t}$ is the percent change in current smoking prevalence from the previous year, and $CSP_{A[a],g,t}$ is the current smoking prevalence by specific age group A, geography g, and time t that point $p_{g,a,t}$ captures, both derived from the current smoking ST-GPR model defined above.

Exposure among current and former smokers

We estimated exposure among current smokers for two continuous indicators: cigarettes per smoker per day and pack-years. Pack-years incorporates aspects of both duration and amount. One pack-year represents the equivalent of smoking one pack of cigarettes (assuming a 20 cigarette pack) per day for one year. Since the pack-years indicator collapses duration and intensity into a single dimension, one pack-year of exposure can reflect smoking 40 cigarettes per day for six months or smoking 10 cigarettes per day for two years.

To produce these indicators, we simulated individual smoking histories based on distributions of age of initiation and amount smoked. We informed the simulation with cross-sectional survey data capturing these indicators, modelled at the mean level for all locations, years, ages, and sexes using spatiotemporal Gaussian process regression. We rescaled estimates of cigarettes per smoker per day to an envelope of cigarette consumption based on supply-side data. We estimated pack-years of exposure by summing samples from age- and time-specific distributions of cigarettes per smoker for a birth cohort in order to capture both age trends and time trends and avoid the common assumption that the amount someone currently smokes is the amount they have smoked since they began smoking. All distributions were age-, sex-, and region- specific ensemble distributions, which were found to outperform any single distribution.

We estimated exposure among former smokers using years since cessation. We utilised spatiotemporal Gaussian process regression to model mean age of cessation using cross-sectional survey data capturing age of cessation. Using these estimates, we generated ensemble distributions of years since cessation for every location, year, age group, and sex.

Risk-outcome pairs

We included the following risk-outcome pairs based on evidence supporting a causal relationship: tuberculosis, lower respiratory tract infections, esophageal cancer, stomach cancer, bladder cancer, liver cancer, laryngeal cancer, lung cancer, breast cancer, cervical cancer, colorectal cancer, lip and oral cancer, nasopharyngeal cancer, other pharyngeal cancer, pancreatic cancer, kidney cancer, leukemia, ischemic heart disease, ischemic stroke, hemorrhagic stroke, subarachnoid hemorrhage, atrial fibrillation and flutter, aortic aneurysm, peripheral arterial disease, chronic obstructive pulmonary disease, other chronic respiratory diseases, asthma, peptic ulcer disease, gallbladder and biliary tract diseases, Alzheimer disease and other dementias, Parkinson disease (protective), multiple sclerosis, type-II diabetes, rheumatoid arthritis, low back pain, cataracts, macular degeneration, and fracture.

Dose-response risk curves

We conducted systematic literature reviews for all risk-outcome pairs identified as being caused by smoking. We extracted effect sizes by cigarettes per smoker per day, pack-years, and years since quitting from cohort and case-control studies. We synthesised these data to produce non-linear dose response curves using a Bayesian meta-regression model. For outcomes with significant differences in effect size by sex or age, we produced sex- or age-specific risk curves.

We estimate risk curves of former smokers compared to never smokers taking into account the rate of risk reduction among former smokers seen in the cohort and case-control studies, and the cumulative exposure among former smokers within each age, sex, location and year group.

PAF calculation

We estimated population attributable fractions based on the following equation:

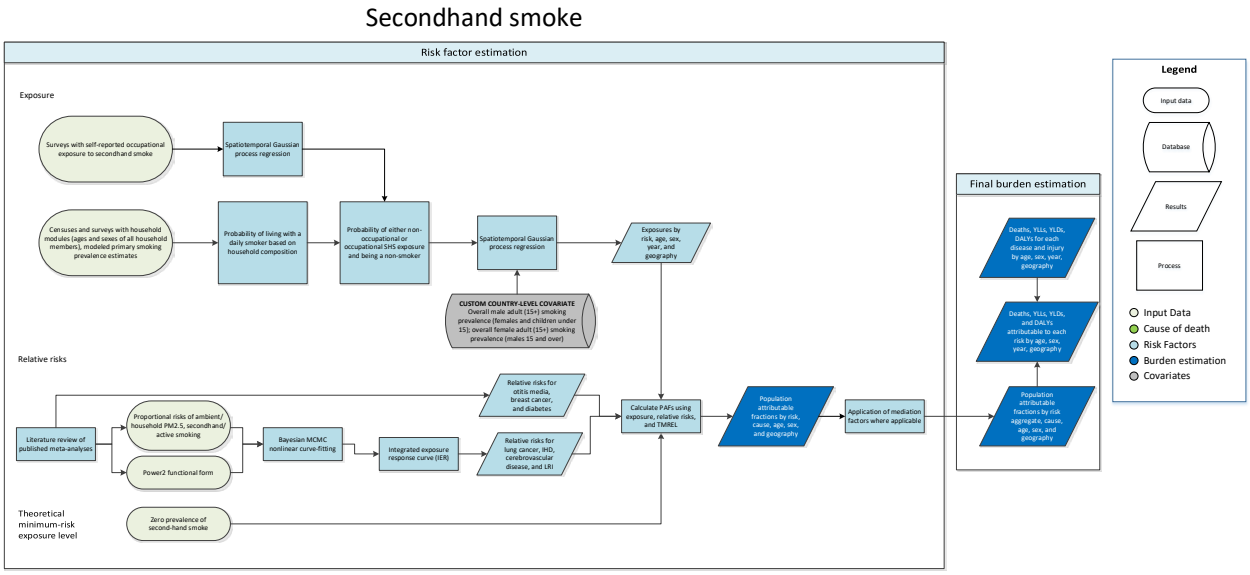
$$PAF = \frac{p(n) + p(f)\int \exp(x) * rr(x) + p(c)\int \exp(y) * rr(y) - 1}{p(n) + p(f)\int \exp(x) * rr(x) + p(c)\int \exp(y) * rr(y)}$$

where $p(n)$ is the prevalence of never smokers, $p(f)$ is the prevalence of former smokers, $p(c)$ is the prevalence of current smokers, $\exp(x)$ is a distribution of years since quitting among former smokers, $rr(x)$ is the relative risk for years since quitting, $\exp(y)$ is a distribution of cigarettes per smoker per day or pack-years, and $rr(y)$ is the relative risk for cigarettes per smoker per day or pack-years.

We used pack-years as the exposure definition for cancers and chronic respiratory diseases, and cigarettes per smoker per day for cardiovascular diseases and all other health outcomes.

Secondhand Smoke Capstone Appendix

Flowchart



Exposure

Case definition

We define secondhand smoke exposure as current exposure to secondhand tobacco smoke at home, at work, or in other public places. We use household composition as a proxy for non-occupational secondhand smoke exposure and make the assumption that all persons living with a daily smoker are exposed to tobacco smoke. We use surveys to estimate the proportion of individuals exposed to secondhand smoke at work. We only consider non-smokers to be exposed to secondhand smoke. Non-smokers are defined as all persons who are not daily smokers. Ex-smokers and occasional smokers are considered non-smokers in this analysis. Exposure is evaluated for both children and adults.

Input data

To calculate the proportion of non-smokers who live with at least one smoker, we used unit record data on household composition, which included the ages and sexes of all persons living in the same household. Our sources included representative major survey series with a household composition module, including the Demographic Health Surveys (DHS), the Multiple Indicator Cluster Surveys (MICS), and the Living Standards Measurement Surveys (LSMS); and national and subnational censuses, which included those captured in the IPUMS project and identified using the Global Health Data Exchange catalog (GHDx).

To calculate the proportion of individuals exposed to secondhand smoke at work, by age and sex, we used cross-sectional surveys that ask respondents about self-reported occupational secondhand smoke exposure. Sources include the Global Adult Tobacco Surveys, Eurobarometer Surveys, and WHO STEPS Surveys. We identified sources using the GHDx.

Estimates of primary smoking prevalence in each location were also used in our calculations. Further details on the estimation of primary smoking prevalence can be found in the Smoking methods appendix.

Modelling strategy

We estimated the probability that each person is living with a smoker and is also a non-smoker themselves using set theory. First, household composition data were used at the individual level to capture the ages and sexes of each person in the household. Second, we analyzed surveys with both household composition data and tobacco use questions and determined that the distribution of household size, mean age of the household members, and the age distribution were not significantly different between households with and without a self-reported smoker. Since we did not find that household composition varied between smokers and non-smokers, we then used the GBD 2017 primary smoking prevalence model to calculate the probability that each household member is a smoker. Next, we used the probability of the union of sets on each individual household member to calculate the overall probability that at least one of the other household members was a smoker. We incorporated occupational exposure by modelling prevalence of current exposure to secondhand smoke at work, by age, sex, location, and year, using ST-GPR. In order to avoid double counting we calculated the probability that an individual is exposed through either non-occupational exposure or occupational exposure, given their age, sex, and household composition. Finally, we multiplied this probability of exposure by the probability that the individual is not a smoker themselves (i.e. 1 minus primary smoking prevalence for that person's location, year, age, and sex). We then collapse these individual-level probabilities to produce average probabilities of exposure by location, year, age, and sex.

These probabilities were modelled in the GBD ST-GPR framework, which generates exposure estimates from a mixed effects hierarchical linear model plus weighted residuals smoothed across time, space, and age. The linear model formula was fit separately by sex using restricted maximum likelihood in R.

We used the sex-specific overall smoking prevalence for adults (age 15 and older) as a country-level covariate in the model. The overall male adult daily smoking prevalence was used as the covariate for females of all ages and for males under age 15. The overall female adult daily smoking prevalence was used as the covariate for males age 15 and older. This was a modelling change from GBD 2015, in which we used the male age-standardised smoking prevalence for the adult female and children under 15 model, and the female age-standardised smoking prevalence for the adult male model.

All input data points from the probability calculation had a measure of uncertainty (variance and sample size) coming from the uncertainty of the primary smoking prevalence model and the sample size from the unit record data going into the modelling process. Geographic random effects were used in model fitting but were not used in prediction.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for secondhand smoke is zero exposure among non-smokers, meaning that non-smokers would not live with any primary smokers.

Relative risks

For children ages 0-14, we estimated the burden of otitis media attributable to secondhand smoke exposure. For all ages we estimated the burden of lower respiratory infections (LRI), and for adults

greater or equal to 25 years of age we estimated the burden of lung cancer, chronic obstructive pulmonary disease (COPD), ischemic heart disease, and cerebrovascular disease attributable to secondhand smoke exposure, breast cancer, and type-II diabetes.

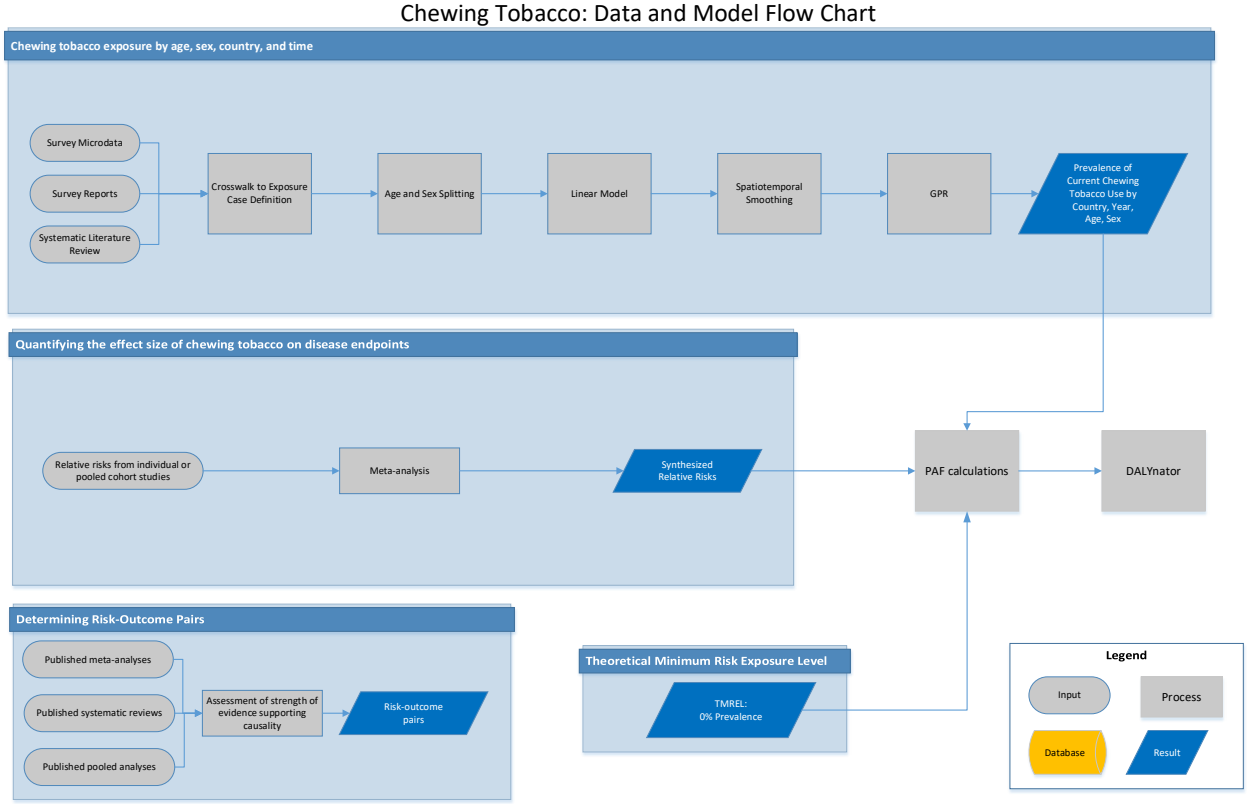
For lung cancer, ischemic heart disease, cerebrovascular disease, and LRI, we used country-specific relative risks created using integrated exposure response curves (IER) for PM2.5 air pollution. The relative risks for otitis media, breast cancer, and diabetes are derived from published meta-analyses.

We used the standard GBD population attributable fraction (PAF) equation to estimate burden based on exposure and relative risks.

Chewing Tobacco Capstone Appendix

Flowchart

Chewing Tobacco: Data and Model Flow Chart



In GBD 2016, we estimated age-sex specific current smokeless tobacco use prevalence for all countries and territories from 1990-2016 using all available data. The estimated prevalence was then attributed to either all chewing tobacco, or all snus/snuff by country, based on input from smokeless tobacco experts.

For GBD 2017, we have changed the exposure definition from current smokeless tobacco use to current chewing tobacco use, based on the strength of evidence supporting the health effects of chewing tobacco use. By estimating chewing tobacco exposure in all countries and territories, burden is now estimated for locations previously classified as predominantly snus/snuff, but still have non-negligible use of chewing tobacco.

Input data

Inclusion criteria

We included sources that reported primary chewing tobacco use among respondents over age 10. To be eligible for inclusion, sources had to be representative for their level of estimation (ie. National sources needed to be nationally representative, subnational sources subnationally representative). We included only self-reported chewing tobacco use data and excluded data from questions asking about others' tobacco use behaviors. We included data collected between 1 January 1980 and 1 January 2018.

Prevalence

We searched the Global Health Data Exchange (GHDx) database for primary data sources with the keyword “Tobacco Use” on January 1, 2018 to ensure all available data sources were captured. Of the 3,318 sources identified in the GHDx, 1,578 country-year sources met inclusion criteria and were included.

In addition to the primary data sources identified through the GHDx, we performed a systematic literature search on PubMed. The search was conducted on January 19, 2017 and returned 5982 hits, of which 267 were eligible for inclusion. Of these 267 sources, 200 had already been identified in the GHDx, so the Pubmed search yielded 67 additional sources overall. The search string is shown below: ("smokeless tobacco"[tiab] OR "Tobacco, Smokeless"[Mesh] OR bajjar[tiab] OR ("betel quid"[tiab] AND tobacco[tiab]) OR "chewing tobacco"[tiab] OR chimó[tiab] OR snuff[tiab] OR snuif[tiab] OR dip[tiab] OR dohra[tiab] OR gudakhu[tiab] OR gul[tiab] OR gutka[tiab] OR gutkha[tiab] OR "hnat hsey"[tiab] OR iq’mik[tiab] OR khaini[tiab] OR kharra[tiab] OR khiwam[tiab] OR khimam[tiab] OR kiwam[tiab] OR kimam[tiab] OR "lal dant manjan"[tiab] OR ("loose leaf"[tiab] AND (chew[tiab] OR tobacco[tiab])) OR mainpuri[tiab] OR maras[tiab] OR mawa[tiab] OR mshri[tiab] OR naffa[tiab] OR nas[Supplementary Concept] OR ((nas[tiab] OR nass[tiab]) AND tobacco[tiab]) OR naswar[tiab] OR nasway[tiab] OR nasvay[tiab] OR neffa[tiab] OR ((pan[tiab] OR paan[tiab]) AND tobacco[tiab]) OR (plug[tiab] AND tobacco[tiab]) OR (rapé[tiab] AND tobacco[tiab]) OR ((red[tiab] OR tobacco[tiab]) AND (toothpowder[tiab] OR toothpaste[tiab])) OR shammah[tiab] OR snus[tiab] OR taaba[tiab] OR tapkeer[tiab] OR tawa[tiab] OR tombol[tiab] OR toombak[tiab] OR tuibur[tiab] OR "tobacco water"[tiab] OR (twist[tiab] AND tobacco[tiab]) OR zarda[tiab]) AND Humans[Mesh] AND English[Language] NOT Case Reports[ptyp]

Prevalence data preprocessing

Data extraction

We extracted primary data from individual-level microdata and survey report tabulations. We extracted data on current, former, and/or ever chewing tobacco use as well as frequency of use (daily, occasional, and unspecified, which includes both daily and occasional smokers). Products that do not include tobacco, such as betel quid without tobacco, were excluded or estimated separately as part of the drug use risk factor, if applicable.

For microdata, we extracted relevant demographic information, including age, sex, location, and year, as well as survey metadata, including survey weights, primary sampling units, and strata. This information allowed us to tabulate individual-level data in the standard GBD five-year age-sex groups and produce accurate estimates of uncertainty. For survey report tabulations, we extracted data at the most granular age-sex group provided.

Crosswalk

Our GBD chewing tobacco case definition is current use of chewing tobacco. All other data points measuring other types of chewing tobacco prevalence were adjusted to be consistent with this definition. Some sources contained information on more than one case definition and these sources were used to develop the adjustment coefficient to transform alternative case definitions to the GBD case definition. The adjustment coefficient was the beta value derived from a linear model with one predictor and no intercept.

We generated separate crosswalk coefficients for the 10-14 age group and the 15-19 age group, as we found the relationships between case definitions differed strongly in the younger age groups compared to the 20+ age groups. To account for this, we attempted to generate a global crosswalk coefficient for both the 10-14 and 15-19 age groups, using the same regression as above. Due to data limitations, none of the crosswalk coefficients met the criteria outlined above, so no data covering youths under 20 years old were crosswalked. In other words, all data from these age groups that appear in the model were asked according to our case definition in the survey.

We propagated uncertainty at the survey level from the crosswalk by incorporating both the variance of the errors and the variance of the adjustment coefficients.

For each source that needed adjusting, we assigned space weights based on GBD region and superregion to the sources containing more than one case definition. Data from the same region receiving a full weight of 1, and data from the same super-region received a weight of ½. We explored using a time weight, to control for possible changes in the relationship between chewing tobacco use behaviors over time. We found incorporating temporal information did not significantly change the estimated coefficients but did undercut sample sizes, and chose to exclude the time weight. Crosswalk coefficients generated from fewer than 20 data sources were dropped.

Age and sex splitting

We split data reported in broader age groups than the GBD 5-year age groups or as both sexes combined by adapting the method reported in Ng et al. (http://jamanetwork.com/journals/jama/fullarticle/1812960) to split using a sex- geography- time specific reference age pattern. We separated the data into two sets: a training dataset, with data already falling into GBD sex-specific 5-year age groups, and a split dataset, which reported data in aggregated age or sex groups. We then used spatiotemporal Gaussian Process Regression (ST-GPR) to estimate sex-geography-time specific age patterns using data in the training dataset. The estimated age patterns were then used to split each source in the split dataset.

The ST-GPR model used to estimate the age patterns for age-sex splitting used an age weight parameter value that minimizes the effect of any age smoothing. This parameter choice allows the estimated age pattern to be driven by data, rather than being enforced by any smoothing parameters of the model. Because these age-sex split data points will be incorporated in the final ST-GPR exposure model, we do not want to doubly enforce a modelled age pattern for a given sex-location-year on a given aggregate data point.

Chewing tobacco prevalence modelling

We used ST-GPR to model chewing tobacco prevalence. Full details on the ST-GPR method are reported elsewhere in the Appendix. Briefly, the mean function input to GPR is a complete time series of estimates generated from a mixed effects hierarchical linear model plus weighted residuals smoothed across time, space and age. The linear model formula for chewing tobacco, fit separately by sex using restricted maximum likelihood in R, is:

$$logit(p_{g,a,t}) = \beta_0 + \sum_{k=1}^{18} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_g + \epsilon_{g,a,t}$$

Where $I_{A[a]}$ is a dummy variable indicating specific age group A that the prevalence point $p_{g,a,t}$ captures, and α_s, α_r, and α_g are super region, region, and geography random intercepts, respectively. Random effects were used in model fitting but not in prediction.

The hyperparameters for ST-GPR were as follows: age weight = 0.87 for data density below 10 and 1.48 for data density above 10, time weight of 0.04, space weight of 0.01 for data density below 10 and 0.005 for data density above 10, and scale = 20. Amplitude was calculated at the region level. Hyperparameters were decided based on a random grid search evaluated on out of sample RMSE performed on direct smoking data, but due to computational time was not able to be applied to the chewing tobacco data.

Estimating attributable burden

Assessment of risk-outcome pairs

We included outcomes based on the strength of available evidence supporting a causal relationship. There was sufficient evidence to include oral cancer and oesophageal cancer as health outcomes caused by chewing tobacco use. Appendix Table 4 reports the strength of evidence for included outcomes.

Relative risk

Relative risk estimates were derived from prospective cohort studies and population-based case-control studies. Sources used in relative risk estimation are reported in Appendix Table 4.

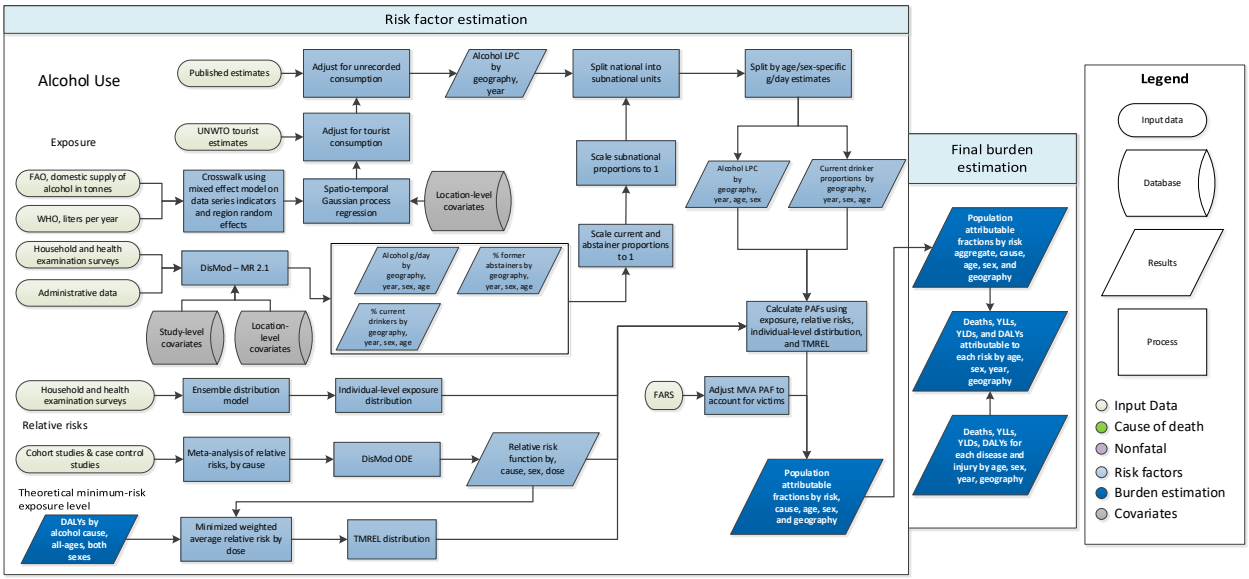
Appendix Table 6a reports relative risk estimates and uncertainty for the two outcomes included in the analysis, by sex. We extracted the underlying effect size estimates from prospective cohort studies and population-based case-control studies identified by performing a systematic literature review as well as by reviewing the underlying studies included in published meta-analyses. We did not include hospital-based case control studies due to concerns over representativeness. We only included sources that adequately adjusted for major confounders, especially smoking status. Summary effect size estimates were calculated in R, using the 'metafor' package. We performed a random effects meta-analysis using the DerSimonian and Laird method, which does not assume a true effect size but considers each input study as selected from a random sample of all possible sets of studies for the outcome of interest. The random-effects method allows for more variation between the studies, and incorporates this variance into the estimation process. We used an inverse-variance weighting method to determine component study weights. We found significantly different relative risks for oral cancer for males and females, and estimated relative risks separately by sex for oral cancer alone.

Theoretical minimum risk exposure level

The theoretical minimum risk exposure level is that everyone in the population has been a lifelong non-user of chewing tobacco.

Alcohol Use Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

We defined exposure as the grams per day of pure alcohol consumed amongst drinkers. We constructed this exposure using the indicators outlined below:

1. Current drinkers, defined as the proportion of individuals who have consumed at least one alcoholic beverage (or some approximation) in a 12-month period.
2. Lifetime abstainers, defined as the proportion of individuals who have never consumed an alcoholic beverage.
3. Alcohol consumption (in grams per day), defined as grams of alcohol consumed by current drinkers, per day, over a 12-month period.
4. Alcohol liters per capita stock, defined in liters per capita of pure alcohol, over a 12-month period.

We also used three additional indicators to adjust alcohol exposure estimates to account for different types of bias:

1. Number of tourists within a location, defined as the total amount of visitors to a location within a 12 month period.
2. Tourists' duration of stay, defined as the number of days resided in a hosting country.

3. Unrecorded alcohol stock, defined as a percentage of the total alcohol stock produced outside established markets.

Input data

A systematic review of the literature was performed to extract data on our primary indicators. The Global Health Exchange (GHDx), IHME's online database of health-related data, was searched for population survey data containing participant-level information from which we could formulate the required alcohol use indicators on current drinkers, lifetime abstainers, alcohol consumption, and binge drinkers. Data-sources were included if they captured a sample representative of the geographic location under study. We documented relevant survey variables from each data-source in a spreadsheet and extracted using STATA 13.1 and R 3.3 . A total of 2,821 potential data-sources were available in the GHDx across countries with subnational locations, out of which 191 data-sources (corresponding 88,734 tabulated data-points by location/year/sex/age) were included across the four indicators mentioned above.

Within the grams per day, current drinkers, and abstainers model, we had a large amount of data on male drinking but not female drinking. To ensure a balanced dataset between sexes for use within DisMod MR 2.1, we imputed for missing sex observations within locations where data existed on male drinking but not female drinking. We used the following models to do so:

For grams per day:

$$y_i \sim Gamma(\mu, \phi)$$
$$\mu = log^{-1}(1 + SDI + sex + age + sex * age + (1 + sex|super\ region) + (1 + sex|region)$$

Where y is average amount of grams per day within a demographic, μ a parameter for the mean of the average amounts, and ϕ is a dispersion parameter

For current drinking and abstention:

$$y_i \sim Binomial(\pi_i, n)$$
$$\pi_i \sim Beta(\mu_i, \theta_i)$$
$$\mu_i = cloglog^{-1}(1 + SDI + sex + age + sex * age + (1 + sex|super\ region) + (1 + sex|region)$$

We then sampled 1000 draws from the above estimator for both sex = male & sex = female, with all other variables fixed by demographic unit. For sampling draws, we assumed the parameters were Gaussian multivariately distributed. For each demographic unit with only male observations, we multiplied male data by the ratio between the draws with sex = male & sex = female to impute for female observations.

To generate estimates of alcohol consumption in liters per capita (LPC), we obtained data from FAOSTAT, and WHO GISAH database.[1,2] To provide more stable time trends in the model, we transformed FAO sales data (which calculates stock based on primary inputs) to a lagged five-year average. Given WHO uses FAO data in locations where WHO could not find data using their own methods, we removed FAO data in the locations where WHO used FAO data in place of their own. To correct for bias in the underlying data sources, we adjusted the input data (crosswalked), by running a mixed effect model on the log average of the data with dummy variables for the data series, as well as random effects on super region, region, country, and time. We adjusted the data points using the following equation:

$$Log\ Average\ Data = D + (Super\ Region\ |D, Region\ |\ D, Country\ |D, Year|\ D)$$

$$Transformed\ data = \ data\ *\ e^{\widehat{\beta_1} + \widehat{\beta_3}}$$

where:

$$D\ is\ a\ dummy\ variable\ for\ a\ data\ source$$

None of the data sources on liters per capita provided estimates of uncertainty, which is a component required for our eventual modelling strategy. To generate uncertainty, we ran a Loess model on the adjusted data points and the standard deviation between the difference of the Loess smoothed model and the adjusted data points across a five-year span was used as the standard deviation of the data. (i.e., if the total stock changes more variably in a narrow time frame, we believe the data to be more uncertain).

We obtained data on the number of tourists and their duration of stay from the UNWTO.[3] We applied a crosswalk across different tourist categories, similar to the one used for the liters per capita data, to arrive at a consistent definition (i.e. visitors to a country).

We obtained estimates on unrecorded alcohol stock from six published papers,[4-9] consisting of 166 locations.

Modelling strategy

While population-based surveys provide accurate estimates of the prevalence of lifetime abstainers and current drinkers, they typically underestimate real alcohol consumption levels.[10-12] As a result, we considered the liter per capita input to be a better estimate of overall volume of consumption. Per capita consumption, however, does not provide age- and sex-specific consumption estimates needed to compute alcohol-attributable burden of disease. Therefore, we use the age-sex pattern of consumption among drinkers modelled from the population survey data and the overall volume of consumption from FAO and GISAH to determine the total amount of alcohol consumed within a location. In the paragraphs we outline how we estimated each primary input in the alcohol exposure model, as well as how we combined these inputs to arrive at our final estimate of grams per day of pure alcohol. We estimated all models below using 1,000 draws.

For data obtained through surveys, we used DisMod-MR 2.1 to construct estimates for each country/year/age/sex. We chose to use DisMod due to its ability to leverage information across the heterogeneous age groups reported in the surveys, through age-integration, as well as the model's ability to leverage information available from data in nearby locations or time-periods.[13]

We modelled the alcohol liters per capita data, as well as the total number of tourists, using a spatio-temporal Gaussian process regression (ST-GPR). We chose parameters, as well as our final model, using out-of-sample 10-fold cross validation.

Given the heterogeneous nature of the estimates on unrecorded consumption, as well as the wide variation across countries and time-periods, we took 1,000 draws from the uniform distribution of the lowest and highest estimates available for a given country. We did this to incorporate the diffuse

uncertainty within the unrecorded estimates reported. We used these 1,000 draws in the above equation. We adjusted LPC only for countries where estimates were available.

We adjusted the alcohol LPC for unrecorded consumption using the following equation:

$$Alcohol\ LPC = \frac{Alcohol\ LPC}{(1 - \%\ Unrecorded)}$$

We then adjusted the estimates for alcohol LPC for tourist consumption by adding in the per capita rate of consumption abroad and subtracting the per capita rate of tourist consumption domestically.

$$Alcohol\ LPC_d = Unadjusted\ Alcohol\ LPC_d + Alcohol\ LPC_{\,Domestic\ consumption\ abroad} - Alcohol\ LPC_{\,Tourist\ consumption\ domestically}$$

$$Alcohol\ LPC_{\,i} = \frac{\sum_l Tourist\ Population_{\,l} * Proportion\ of\ tourists_{\,i,l} * Unadjusted\ Alcohol\ LPC_{\,l} * \frac{Average\ length\ of\ stay_{\,i,l}}{365} *}{Population_{\,d}}$$

where:

$l\ is\ the\ set\ of\ all\ locations, i\ is\ either$ Domestic consumption abroad or Tourist consumption domestically, $and\ d\ is\ a\ domestic\ location$

After adjusting alcohol LPC by tourist consumption and unrecorded consumption for all location/years reported, sex-specific and age-specific estimates were generated by incorporating estimates modelled in DisMod for percentage of current drinkers within a location/year/sex/age, as well as consumption trends modelled in the DisMod g/day model. We do this by first making sure the sum of percent current drinkers and percent abstainers sum to one for a given location/year/age/sex. We then calculate the proportion of total consumption for a given location/year by age and sex, using the estimates of alcohol consumed per day, the population size, and the percentage of current drinkers. Lastly, we then multiply this proportion of total stock for a given location/year/sex/age by the total stock for a given location/year to calculate the consumption in terms of liter per capita for a given location/year/sex/age. We then convert these estimates to be in terms of grams/per day. The following equations describe these calculations:

$$\%\ Current\ drinkers_{\,l,y,s,a} = \frac{\%\ Current\ drinkers_{\,l,y,s,a}}{\%\ Current\ drinkers_{\,l,y,s,a} + \%\ Abstainers_{l,y,s,a}}$$

$$Proportion\ of\ total\ consumption_{\,l,y,s,a} = \frac{Alcohol\ \ g/day_{\,l,y,s,a} * Population_{\,l,y,s,a} * \%\ Current\ drinkers_{\,l,y,s,a}}{\sum_{s,a} Alcohol\ \ g/day_{\,l,y,s,a} * Population_{\,l,y,s,a} * \%\ Current\ drinkers_{\,l,y,s,a}}$$

$$Alcohol\ LPC_{l,y,s,a} = \frac{Alcohol\ LPC_{l,y} * Population_{l,y} * Proportion\ of\ total\ consumption_{l,y,s,a}}{\%\ Current\ drinkers_{l,y,s,a} * Population_{l,y,s,a}}$$

$$Alcohol\ g/day_{l,y,s,a} = Alcohol\ LPC_{l,y,s,a} * \frac{1000}{365}$$

where:

$l\ is\ a\ location, y\ is\ a\ year, s\ is\ a\ sex, and\ a\ is\ an\ age\ group.$

We then used the gamma distribution to estimate individual level variation within location, year, sex, age drinking populations, following the recommendations of other published alcohol studies.[7,8] We chose parameters of the gamma distribution based on the mean and standard deviation of the 1,000 draws of alcohol g/day exposure for a given population.

Theoretical minimum-risk exposure level

We calculated TMREL by first calculating the overall risk attributable to alcohol. We did this by weighting each relative risk curve by the share of overall DALYs for a given cause. We then took the minimum of this overall-risk curve as the TMREL of alcohol-use. More formally,

$$TMREL = argmin\ average\ overall\ risk_{\omega}(g/day)$$

$$Average\ overall\ risk_{\omega}(g/day) = \sum_{i}^{\omega} RR_i(g/day) * \frac{DALY_i}{\sum_i^{\omega} DALY_i}$$

Where:

$\omega\ is\ the\ set\ of\ causes\ associated\ with\ alcohol, i\ is\ a\ given\ cause\ from\ that\ set,$
$DALY\ is\ the\ global\ DALY\ rate\ in\ 2010, and\ RR\ is\ the\ dose\ response\ curve\ for\ a\ given\ cause$
$and\ exposure\ level\ in\ grams\ per\ day.$

In other words, we chose TMREL as being the exposure that minimises your risk of suffering burden from any given cause related to alcohol. We weight the risk for a particular cause in our aggregation by the proportion of DALYs due to that cause. (e.g. since more observed people die from IHD, we weight the risk for IHD more in the above calculation of average risk compared to, say, diabetes, even if both have the same relative risk for a given level of consumption)

Relative risks

For GBD 2016, we performed a systematic literature review of all cohort and case-control studies reporting a relative risk, hazard ratio, or odds ratio for any risk-outcome pairs studied in GBD 2016. Studies were included if they reported a categorical or continuous dose for alcohol consumption, as well as uncertainty measures for their outcomes, and the population under study was representative. Relative risk estimates by dose can be found in Appendix Table 6c.

We then used these studies to calculate a dose-response, modelled using DisMod ODE. We chose DisMod ODE rather than a conventional mixed effect meta-regression because of its ability to estimate nonparametric splines over doses (i.e. for most alcohol causes, there is a non-linear relationship with different doses) and incorporate heterogeneous doses through dose-integration (i.e. most studies report doses categorically in wide ranges. DisMod ODE estimates specific doses when categories overlap across studies, through an integration step.) We used the results of the meta-regression to estimate a non-parametric curve for all doses between 0-150 g/day and their corresponding relative risks. For all causes, we assumed the relative risk was the same for all-ages and sexes, with the exception of ischemic heart disease, ischemic stroke, hemorrhagic stroke, and diabetes, which we estimated by sex.

Regarding injuries outcomes, we constructed relative risks based on chronic exposure rather than acute, which has a weaker relationship to the outcome, though still significant.[15,16,18-21] We decided to use chronic exposure given the lack of available data on acute exposure, as well as, the lack of cohort studies using acute exposure as a metric. Further, using chronic exposure allowed us to construct relative risks curves for unintentional injuries, interpersonal violence, motor vehicle accidents, and self-harm using the same method as reported above.

In the case of motor vehicle accidents, we adjusted the PAF to account for victims of drunk drivers that are involved in accidents. Using data from the Fatality Analysis Reporting System in the US,[17] we calculated the average number of fatalities in a car crash involving alcohol, as well as the percentage of those fatalities distributed by age and sex (figures 1 and 2). We aggregated FARS data across the years 1985-2015, given there was little variation in the data temporally and the number of cases in old age groups had too much variance when constructing estimates by year. To adjust PAFs, we multiplied attributable deaths by the average number of fatalities from FARS and redistributed the PAF amongst each population, based on the probability of being a victim to a certain drunk driver by age and sex, based on the FARS data. The following equation describes this process:

$$Adjusted\ PAF_i = \frac{\sum_d PAF_d * DALY_d * Avg\ Fatalities_d * P(i\ is\ a\ victim)_d}{DALY_i}$$

where:

$i\ is\ a\ population\ by\ location, year, age, sex\ and$
$d\ is\ the\ set\ of\ all\ age\ and\ sex\ exposed\ groups\ within\ that\ location\ and\ year.$

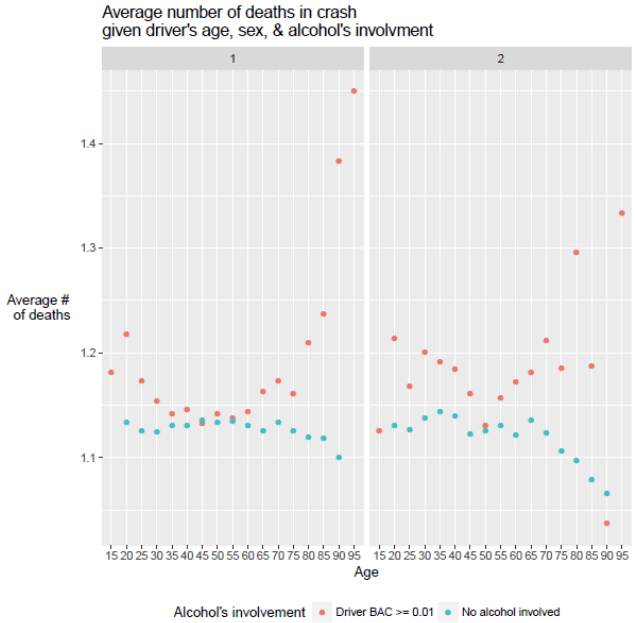


Figure 1

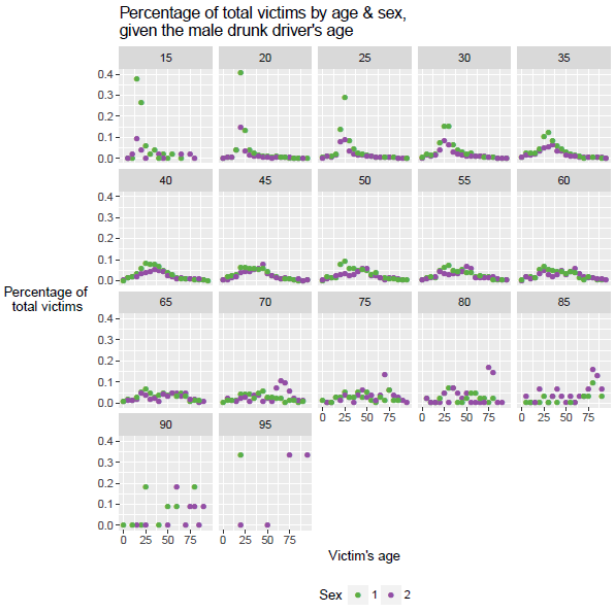

Figure 2

Population attributable fraction

For all causes, we defined PAF as:

$$PAF(x) = \frac{P_A + \int_0^{150} P(x) * RR_C(x)\, dx - 1}{P_A + \int_0^{150} P(x) * RR_C(x)\, dx} \qquad P(x) = P_C * \Gamma(\boldsymbol{p})$$

where:

P_C *is the prevalence of current drinkers,* P_a *is the prevalence of abstainers,* $RR_c(x)$ *is the relative risk function for current drinkers, and* $\boldsymbol{p}$ *are parameters determined by the mean and sd of exposure*

We performed the above equation for 1,000 draws of the exposure and relative risk models. We then used the estimated PAF draws to calculate YLL, YLDs, and DALYs, as per the other risk factors.

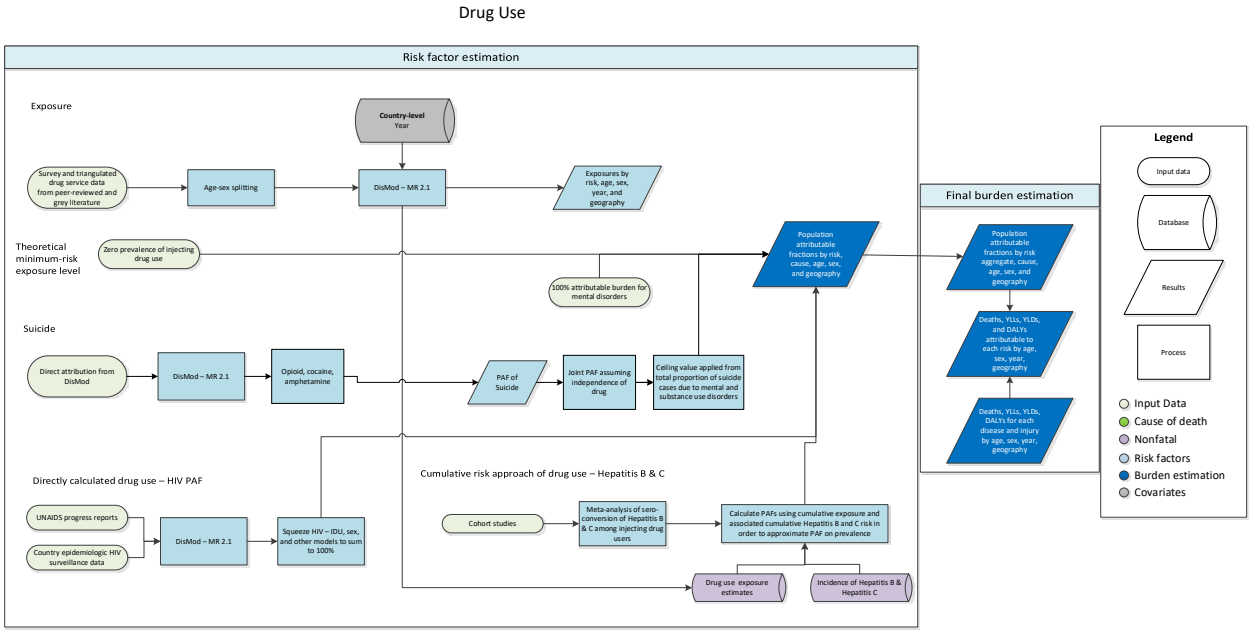
Injecting Drug Use Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Injecting drug users (IDU) are at high risk from blood-borne infections, including human immunodeficiency virus (HIV) and Hepatitis B and C viruses (HBV and HCV, respectively), through the use of shared needles and injection equipment. In GBD 2010, based on the available epidemiological literature and the availability of exposure estimates[1,2] we measure the burden of disease attributable to HIV, HBV and HCV due to injecting drug use. An injecting drug user was defined as a current or recent user aged 15-64 years old.

Input data

The major burden of mortality from viral hepatitis is due to cirrhosis and liver cancer resulting from chronic hepatitis infection. Cirrhosis mortality was modelled with vital registration data using CODEm. Etiologic proportion models, estimated using DisMod-MR 2.1, were used to split the overarching cirrhosis mortality estimates into cases of cirrhosis attributable to hepatitis B, hepatitis C, alcohol, and other causes.[1-4]

Liver cancer mortality was modelled using cancer registry data. The incidence numbers were transformed into mortality estimates using mortality to incidence ratios. The mortality estimates from cancer registries were then combined with vital registration system data as input data into CODEm, which produced the final mortality estimates for liver cancer. As with cirrhosis mortality, etiologic

proportions for liver cancer due to hepatitis B, and C, alcohol, and other causes were generated using DisMod-MR 2.1.

To estimate the burden of HIV cases attributable to IDU, we extracted data on the proportion of notified HIV cases by transmission route – sexual intercourse, injecting drug use, commercial sex work and other -- from a number of agencies that conduct surveillance of HIV across the globe.[6-13]

The prevalence of current injecting drug use was estimated using data from a 2008 review conducted by the Reference Group to the UN on HIV and injecting drug use,[15] and a new review currently being conducted by international collaborations and experts. The reviews used a multistage process of systematic review adhering to international guidelines. It involved multiple stages of peer and expert review, with searches of the peer-reviewed literature in addition to an extensive review of online grey literature databases in the drug and alcohol and HIV fields. Additional data on the age and sex distribution of injecting drug use were sourced for this modelling exercise.

In order to generate a pooled incidence rate/absolute relative risk for viral hepatitis among people who inject drugs, we conducted a meta-analysis of longitudinal epidemiological studies that reported a hepatitis B[16-20] or hepatitis C[16-31] incidence rate among PWID. We calculated confidence intervals for the incidence rate (where no CI was reported) from a Poisson distribution around the number of cases.

We excluded studies that focused on non-representative subgroups, such as recent injectors or adolescents or because hepatitis incidence is far higher in those groups than for all people who inject drugs (e.g. Larney et al.[32]) We did not vary incidence among active injectors according the availability of blood borne virus prevention strategies (e.g. NSPs, opioid substitution therapy) because too few studies have examined different levels of incidence according to variable coverage, and we were not able to estimate coverage by country over time. In any case, in most countries, coverage of virus prevention strategies remains very low among people who inject drugs,[33] and would have been negligible in most countries until recent years.

Modelling strategy

As part of the GBD 2017 study, we measured the burden of hepatitis B and hepatitis C (including attributable cirrhosis and liver cancer) and HIV at the country, regional, and global level for each age-sex group for the years 1990 to 2017. For HIV, hepatitis B and hepatitis C, disease-specific natural history models were used to estimate deaths and YLDs, because the three-state model in DisMod-MR 2.1(susceptible, cases, dead) did not capture the complexity of the disease processes.

Mortality estimation

Mortality due to overall acute hepatitis was modelled with vital registration data using the Cause of Death Ensemble Modelling tool (CODEm), an analytical tool that tests the predictive power of hundreds of models to estimate trends in causes of death.[5] Due to poor coverage of cause of death data for each of the acute hepatitis varieties, four natural history models for hepatitis B and C were used to estimate mortality by deriving incidence from measurements of seroprevalence and then multiplying incidence by case fatality to estimate the number of deaths. These four models were then squeezed so as to fit the parent cause of death model.

We estimated HIV mortality using a modified UNAIDS Spectrum model.[2] This is a compartmental HIV progression model estimates age-specific incidence, prevalence and death rates using methods

described elsewhere.[2] This modelling approach was adapted according to epidemic type, including concentrated and generalized epidemics. For concentrated epidemics, the Spectrum models were corrected for misclassification of HIV deaths and then calibrated to align with vital registration data. For generalised HIV epidemics, we minimised a loss function to select epidemic curves that were most consistent with the prevalence and all-cause mortality data.[2]

Estimation of Years Lived with Disability

For non-fatal estimation, we estimated the incidence of hepatitis B and C using seroprevalence data in DisMod-MR 2.1. For both hepatitis B and C, we use data on the seroprevalence of the hepatitis surface antigen (a marker of chronic infection in hepatitis B and a marker of ever-infection in hepatitis C), excess mortality, and remission, to estimate incidence of both hepatitis infections. Incidence of cirrhosis was also estimated in DisMod using cirrhosis hospital data and cause-specific mortality rate (CSMR) data.

Incidence of liver cancer was derived by dividing mortality by the mortality to incidence ratios, which were then used to predict liver cancer survival. Finally, we estimated prevalence as a function of incidence and survival by splitting prevalence into four phases. Each phase had different disability weights, which were used to generate YLDs for that phase.

Finally, incidence of HIV was also estimated using the UNAIDS Spectrum modelling approach described above in the mortality estimation section.

Burden of HIV attributable to injecting drug use

We then estimated the proportion of HIV cases attributable to three transmission categories (sex, IDU and other) for all country-time periods using DisMod-MR 2.1. The only covariate used in the model was one that added variance to the data points derived from data sources that attributed a portion of HIV cases to "unknown" transmission sources. We scaled the proportions from each of the three transmission models (sex, IDU and other) to ensure that they fit the total HIV transmission envelope by country, year, age and sex.

Burden of hepatitis B and hepatitis C attributable to injecting drug use

To estimate the relative contribution of IDU to hepatitis B and C disease burden at the country, regional and global level, we used a cohort method. We re-calibrated individuals according to history of injecting drug use, and their accumulated risk of incident hepatitis B and C due to IDU. We made use of data on prevalence of current injecting drug use, pooled in DisMod-MR 2.1; a meta-analysis of incidence rates of hepatitis B and hepatitis C among people who inject drugs; and estimates of population-level incidence of hepatitis B and C between 1990 and 2017. We used back extrapolations to estimate incidence before 1990. These steps are detailed below.

To estimate the lifetime risk of being infected with hepatitis B or C, we undertook a cohort analysis for each country, year, age, and sex category and estimated the probability of an individual having been infected in each preceding year. One of the main inputs to this cohort method was the probability of having injected drugs in a specific age cohort in a given calendar year. For example, for a cohort of 40-year-olds in 2015, the relevant probability in 2005 is the estimated prevalence of injecting drug use among 30-year-olds.

In addition to a global time series of estimated prevalence of injecting drug use, we also used the incidence of hepatitis B or C and the sero-conversion rate of hepatitis B and hepatitis C among people who inject drugs for each age-sex-country-year from 1960 to 2013 by 5-year age groups.

1. Incidence rate of Hepatitis B and C in the general population

We modelled the annual incidence rate of hepatitis B and hepatitis C using sero-prevalence data in DisMod-MR 2.1. We assumed a low remission (mean 0.015 and standard error 0.0075)[14] in the hepatitis B model to reflect the small proportion of cases who spontaneously clear the infection. We assumed zero remission for hepatitis C.

2. Prevalence of ever-injecting drug use

DisMod-MR 2.1 was used to estimate the prevalence of injecting drug use with year as a covariate to estimate the trends over time. DisMod makes an average estimate of the change in drug use over the time period from 1990-2017 and we took draws from a normal distribution of the coefficient to project IDU prevalence backward in time to 1960 from baseline level in 1990.

3. Pooled seroconversion hazard of hepatitis C and hepatitis B among people who ever injected drugs

This pooled sero-conversion hazard for both hepatitis C and hepatitis B was derived from a meta-analysis of longitudinal epidemiologic studies described above in the input data section.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level is defined as zero exposure to injecting drug use.

Relative risks

For drug use, there were not substantial changes made to the effect sizes from GBD 2015. We used a pooled absolute risk of Hepatitis C and Hepatitis B among those who have ever used injecting drugs.

In addition to assessing IDU as a risk factor for blood-borne infections, the broader category of mental and substance use disorders is assessed as risk factors for suicide. The suicide burden attributable to mental and substance use disorders is estimated by comparing the current health status with a theoretical-minimum-risk exposure defined as the counterfactual status of the absence of mental and substance use disorders (Ferrari, Norman et al 2014).

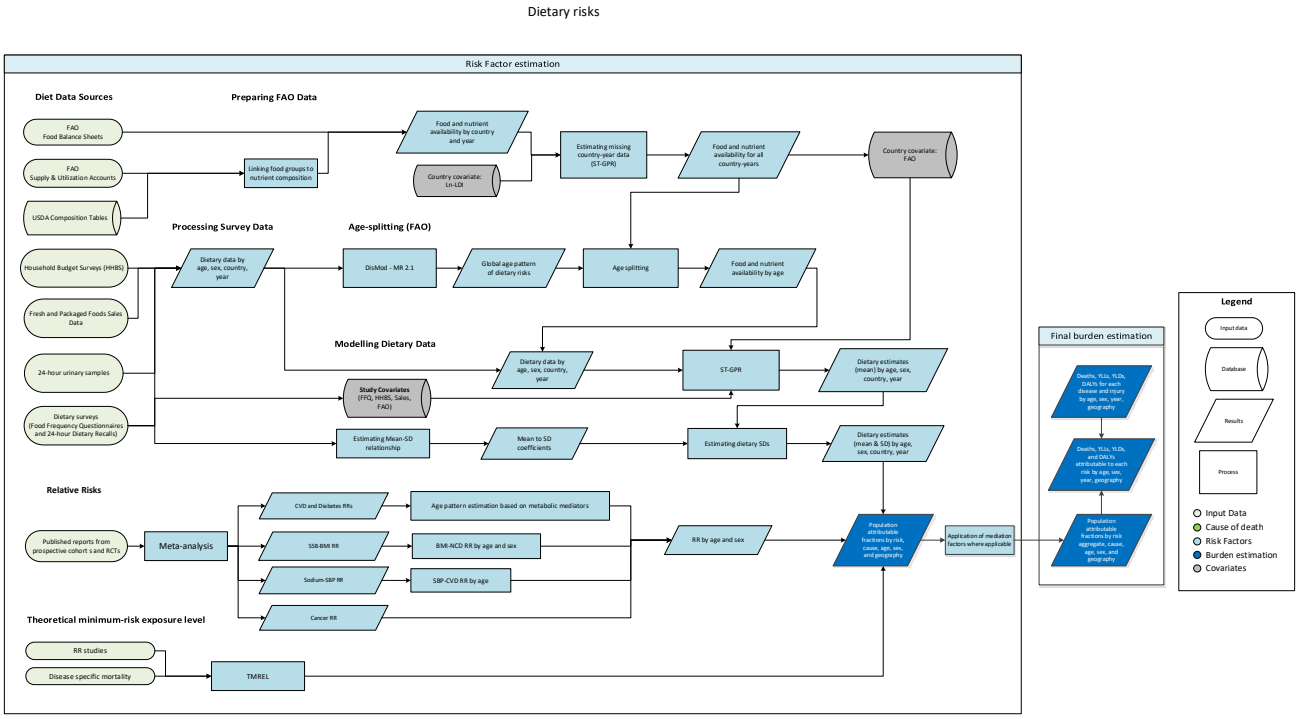
Dietary Risks Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

For GBD 2017, risk factors associated with diet include: diet low in fruits, vegetables, legumes, whole grains, nuts and seeds, fiber, seafood omega-3 fatty acids, polyunsaturated fatty acids, calcium, milk; and diet high in red meat, processed meat, sugar sweetened beverages, trans fatty acids, and sodium. Exposure to a diet low in fruits is defined as average daily consumption of less than 250 grams per day of fruits (fresh, frozen, cooked, canned, or dried, excluding fruit juices and salted or pickled fruits). Exposure to diet low in vegetables is defined as average daily consumption of less than 360 grams per day of vegetables (fresh, frozen, cooked, canned or dried vegetables excluding legumes and salted or pickled vegetables, juices, nuts and seeds, and starchy vegetables such as potatoes or corn). Exposure to a diet low in legumes is defined as average daily consumption of less than 60 grams per day of legumes. Exposure to diet low in whole grains is defined as average daily consumption of less than 125 grams per day of whole grains (bran, germ, and endosperm in their natural proportion) from breakfast cereals, bread, rice, pasta, biscuits, muffins, tortillas, pancakes and other sources. Exposure to diet low in nuts and seeds is defined as average daily consumption of less than 20.5 grams per day of nuts and seeds. Exposure to diet low in milk is defined as average daily consumption of less than 435 grams per day of milk including non-fat, low-fat, and full-fat milk, excluding soy milk and other plant derivatives. Exposure to diet low in calcium is defined as average daily consumption of less than 1.15 grams per day of calcium

from all sources, including milk, yogurt, and cheese. Exposure to diet low in fiber is defined as average daily consumption of less 23.5 grams per day of than fiber from all sources including fruits, vegetables, grains, legumes and pulses. Exposure to diet low in seafood omega-3 fatty acids is defined as average daily consumption of less than 250 milligrams per day of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Exposure to diet low in polyunsaturated fatty acids is defined as average daily consumption of less than 11% of total energy intake from polyunsaturated fatty acids. This represents a change from the last round of GBD where the burden associated with a diet low in polyunsaturated fatty acids was estimated as a replacement for consumption of saturated fatty acids. Exposure to diet high in red meat is defined as average daily consumption of greater than 22.5 grams per day of red meat (beef, pork, lamb, and goat but excluding poultry, fish, eggs, and all processed meats). Exposure to diet high in processed meat is defined as average daily consumption of greater than 2 grams of meat preserved by smoking, curing, salting, or addition of chemical preservatives. Exposure to diet high in sugar sweetened beverages is defined as average daily consumption of greater than 2.5 grams per day of beverages with ≥50 kcal per 226.8 gram serving, including carbonated beverages, sodas, energy drinks, fruit drinks, but excluding 100% fruit and vegetable juices. Exposure to diet high in trans-fatty acids is defined as average daily consumption of greater than 0.5% of trans fat from all sources, mainly partially hydrogenated vegetable oils and ruminant products. Exposure to diet high in sodium is defined as average 24 hour urinary sodium greater than 3 grams per day.

Input data

We used dietary data from multiple sources including nationally and sub-nationally representative nutrition surveys, household budget surveys, accounts of national sales, and United Nations FAO Food Balance Sheets and Supply and Utilization Accounts. A specific improvement for this round was a novel approach we developed that allows the incorporation of FAO-based data to assist with our estimation of whole grains consumption. This is a powerful development as it dramatically increases our data coverage across countries and through time. This was achieved through separate estimation of total grain and refined grain availability. With whole grains and refined grains representing the entirety of all grain available, we were then able to calculate the availability of whole grains by difference. Additionally, for sodium and trans-fatty acids, we used data on 24-hour urinary sodium and availability of hydrogenated vegetable oil in packaged foods, respectively. Polyunsaturated and trans-fatty acids were modelled as a percent of total dietary energy. We modelled missing country-year data from FAO using a space-time Gaussian process regression and lag-distributed country income as the covariate. For each dietary factor, we estimated the global age pattern of consumption based on nutrition surveys (i.e., 24-hour diet recall) and applied that age pattern to the FAO data. Substantive changes in input data compared to GBD 2015 are as follows: (a) re-extracting data from all nutrition surveys and standardising the definition of dietary components across sources; (b) incorporating data gathered through a systematic review of literature for each of our dietary risk factors; (c) using sales data for fruit, vegetables, legumes, processed meats, red meats, sugar-sweetened beverages, and milk.

Modelling strategy

We used a spatio-temporal Gaussian process regression (ST-GPR) framework to estimate the intake of each dietary factor by age, sex, country, and year. In GBD 2017, for all dietary factors other than sodium, we considered data from 24-hour diet recall as the gold standard, and cross-walked other methods of assessment to the gold standard method. For sodium, the 24-hour urinary sodium was considered as the

gold standard. To estimate the 24-hour urinary sodium based on dietary sodium, we performed a crosswalk adjustment between these two types of data.

Table 1 summarises the study-level and country-level covariates used in modelling of each dietary factor.

Table 1. Types of data sources (other than 24-hour dietary recall) and covariates used in modelling of each dietary factor.

	Data Sources				Country level covariate
	Sales	FFQ[1]	HBS[2]	FAO	
Diet low in fruits	●	●	●	●	Lag-distributed income, total available kilocalories per person per day
Diet low in vegetables	●	●	●	●	Lag-distributed income, total available kilocalories per person per day
Diet low in legumes	●	-	●	●	Lag-distributed income, total available kilocalories per person per day
Diet low in whole grains	-	●	-	●	Lag-distributed income
Diet low in nuts and seeds	-	-	●	●	Lag-distributed income, total available kilocalories per person per day
Diet low in milk	●	●	●	●	Lag-distributed income, total available kilocalories per person per day
Diet high in red meat	●	●	●	●	Lag-distributed income, total available kilocalories per person per day
Diet high in processed meat	●	●	●	-	Lag-distributed income
Diet high in sugar-sweetened beverages	●	●	●	-	National availability of sugar (grams/person/day), Lag-distributed income, total available kilocalories per person per day
Diet low in fiber	-	●	-	●	Lag-distributed income, total available kilocalories per person per day
Diet suboptimal in calcium	-	●	-	●	Lag-distributed income, total available kilocalories per person per day
Diet low in seafood omega-3 fatty acids	-	-	-	●	Lag-distributed income
Diet low in polyunsaturated fatty acids	-	●	-	●	Lag-distributed income, total available kilocalories per person per day
Diet high in trans fatty acids	●	●	-	-	-
Diet high in sodium[3]	-	-	-	-	-

[1] Food Frequency Questionnaire
[2] Household Budge Survey
[3] For sodium, we used data from the 24-hour urinary sodium and 24-hour dietary recall.

To characterise the distribution of each dietary factor at population level, we use an ensemble approach that separately fit 12 distributions for individual level microdata to specific to each data source's sampled population. The respective goodness of fit of each family was assessed and a weighting scheme was determined to optimise overall fit to the unique distribution of each risk factor. A global mean of the weights for each risk factor's data sources was created. We then determined the standard deviation of each population's consumption through a linear regression that captured the relationship between

the standard deviation and mean of intake in nationally representative nutrition surveys using 24-hour diet recalls:

$$ln\,(Standard\ deviation)\ =\ \beta_0\ +\ \beta_1\ \times\ ln\,(Mean_i)$$

Then we applied the coefficients of this regression to the outputs of our ST-GPR model to calculate the standard deviation of intake by age, sex, year, and country. We also quantified the within person variation in consumption of each dietary component and adjusted the standard deviations accordingly.

Theoretical minimum-risk exposure level

In GBD 2016, to estimate the TMREL for each dietary factor, we first calculated the level of intake associated with the lowest risk of mortality from each disease endpoint based on the studies included in the meta-analyses of the dietary relative risks. Then, we calculated the TMREL as the weighted average of these numbers using the global number of deaths from each of outcome as the weight (Table 2).

Table 2. Theoretical minimum-risk exposure level for dietary factors GBD 2017.

Dietary Factor	GBD 2017
Fruits	200-300 gr/day
Vegetables	290-430 gr/day
Legumes	50-70 gr/day
Whole grains	100-150 gr/day
Nuts	16-25 gr/day
Red meats	18-27 gr/day
Processed meats	0-4 gr/day
Milk	350-520 gr/day
Sugar sweetened beverages	0-5 gr/day
Polyunsaturated fatty acids	9-13% of total daily energy
Seafood omega-3 fatty acids	200-300 mg/day
Trans fatty acids	0-1% of total daily energy
Dietary fiber	19-28 gr/day
Dietary calcium	1.0-1.3 gr/day

Relative risk

In GBD 2016, we measured the health effects of a diet high in sugar-sweetened beverages (SSBs) through how it changes a population's body-mass index (BMI). All attributed disease burden was then solely through the health outcomes associated with a high BMI. Given the more recent publication of dose-response meta-analyses that quantifies the direct effects of SSB consumption on incidence of and mortality from disease endpoints (i.e., ischemic heart disease, and type-2 diabetes), we have updated

our approach to reflect the best available evidence. In GBD 2017, consistent with other dietary risks, we have estimated the health effects of SSBs on morbidity and mortality from disease endpoints. Considering that the relative risks included in these new meta-analyses were mostly adjusted for BMI, our estimated disease burden reflects the burden of disease attributable to SSB consumption independent of its effect on BMI.

We obtained the relative risk of each disease endpoint per serving of the dietary components from recent dose-response meta-analyses of prospective observational studies, and where available randomised controlled trials. Considering the well-established age trend of the relative risks of metabolic risk factors for cardiovascular disease and diabetes, we conducted a literature review to identify the most important metabolic mediators for each dietary factor and used the age trend of the relative risk of that mediator(s) and the disease endpoint to estimate the age-specific relative risk for each dietary factors (Table 3).

Table 3. Metabolic mediators used to determine the age trend of the effect of dietary factors on cardiometabolic outcomes.

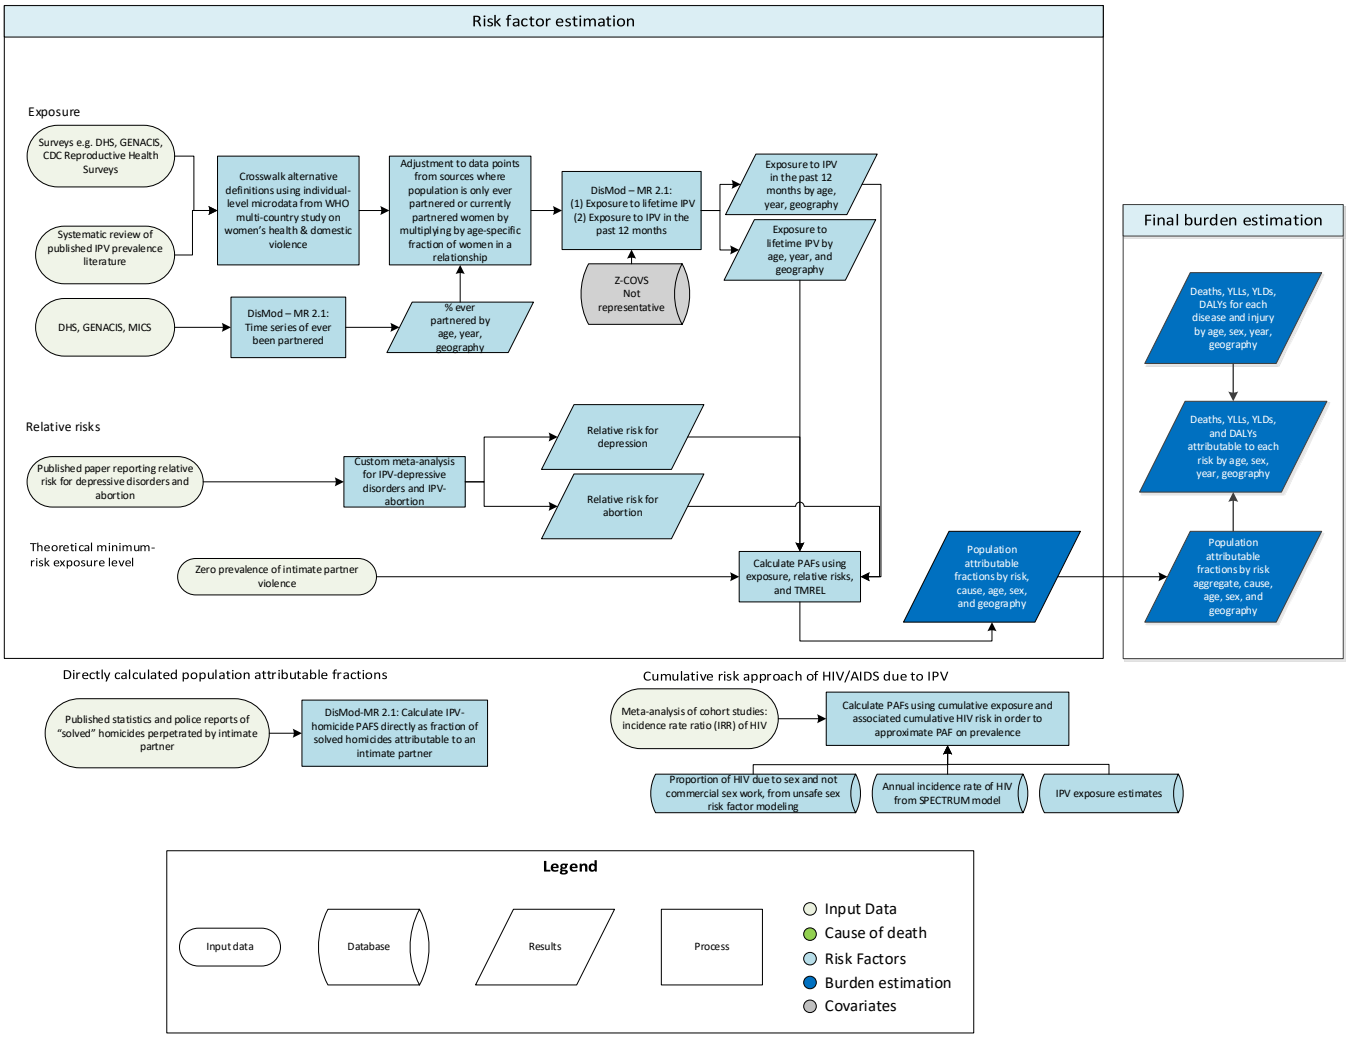
Intimate Partner Violence Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

The case definition for intimate partner violence (IPV) is ever experienced one or more acts of physical and/or sexual violence by a current or former intimate partner since the age of 15 years. Estimated in females only because evidence of risk-outcomes for males does not meet our criteria.

- Physical violence is defined as: 'being slapped or having something thrown at you that could hurt you, being pushed or shoved, being hit with a fist or something else that could hurt, being kicked, dragged, or beaten up, being choked or burnt on purpose, and/or being threatened with or actually having a gun, knife, or other weapon used on you.'

- Sexual violence is defined as: 'being physically forced to have intercourse when you did not want to, having sexual intercourse because you were afraid of what your partner might do, and/or being forced to do something that you found humiliating or degrading' (the definition of humiliating and degrading may vary across studies depending on the regional and cultural setting).
- Intimate partner is defined as: 'a partner to whom you are married or with whom you cohabit.' In countries where people date, dating partners will also be considered (a partner with whom you have an intimate (sexual) relationship with but are not married to or cohabiting).

Input data

No systematic review of the literature was completed for GBD 2017. However, a systematic review of the intimate partner violence prevalence literature was conducted in PubMed for anything published between January 2016 and January 2017 for the GBD 2016 cycle. The following search terms were used to conduct the systematic review:

((("health surveys"[MeSH Terms] AND prevalence[Title/Abstract]) OR ("sentinel surveillance"[MeSH Terms] AND prevalence[Title/Abstract]) OR ("prevalence"[Title/Abstract] AND cross sectional studies[MeSH Terms])) AND (abuse, sexual[MeSH Terms] OR domestic violence[MeSH Terms] OR abuse, partner[MeSH Terms] OR abuse, spousal[MeSH Terms] OR rape[MeSH Terms]) NOT ("comment"[Publication Type] OR "letter"[Publication Type] OR "editorial"[Publication Type]))

We get the proportion of solved homicides that were perpetrated by an intimate partner from crime statistics and police reports.

In GBD 2015, an updated systematic review was done for IPV homicide sources in PubMed through April 2016. The query used for this Pubmed search was:

((IPV[All Fields] OR ("intimate partner violence"[MeSH Terms] OR ("intimate"[All Fields] AND "partner"[All Fields] AND "violence"[All Fields]) OR "intimate partner violence"[All Fields])) AND (("homicide"[MeSH Terms] OR "homicide"[All Fields]) OR femicide[All Fields])) AND ("2013/01/01"[PDAT] : "3000/12/31"[PDAT])

These literature sources were supplemented with sources from the GHDx that were tagged with Intimate partner violence AND Homicide.

Modelling strategy

We use three distinct approaches to estimate burden attributable to IPV, including 1) the traditional exposure and relative risk (RR) to percent attributable fraction (PAF) method for depression and abortion; 2) the direct PAF approach for estimating the proportion of homicides that are perpetrated by an intimate partner; and 3) a cumulative risk approach for estimating the burden of HIV/AIDS attributable to IPV.

Estimating attributable burden to IPV for depression, suicide and abortion

We first adjusted data with variable recall periods (previous 12 months versus lifetime), type of violence (sexual, physical, or both) and severity (severe only versus all levels). To convert data to our reference definition of ever having experienced any physical or sexual IPV, we used data from the WHO Multi-country Study on Women's Health and Domestic Violence against Women to construct crosswalk

regressions. The dependent variable in each of these regressions was ever any IPV (reference), while the key independent variable was one of the 11 alternative metrics of IPV that were represented in our dataset:

1. Physical IPV in the past 12 months
2. Sexual IPV in the past 12 months
3. Severe IPV in the past 12 months
4. Severe physical IPV in the past 12 months
5. Severe sexual IPV in the past 12 months
6. Any IPV (physical and/or sexual) in the past 12 months
7. Ever any physical IPV
8. Ever any sexual IPV
9. Ever any severe IPV
10. Ever severe physical IPV
11. Ever severe sexual IPV

For alternate metrics 1-6 we included a series of age dummies:

$$logit(REF_{ait}) = \beta_0 + \beta_1 logit(ALT_{ait}) + \beta_2 I_a + \varepsilon$$

For alternate metrics 7-11, we ran the following regression:

$$logit(REF_{it}) = \beta_0 + \beta_1 logit(ALT_{it}) + \varepsilon$$

where REF is the reference metric of IPV prevalence, ALT is the alternate metric of IPV prevalence, I_a refers to the complete set of age-group indicators, *a* refers to an age-group, *i* refers to a country, and *t* refers to year. We included age-group indicators in the first six regressions because we expected the prevalence of recent IPV to vary by age. Using the intercepts, coefficients, and variance-covariance matrix from each of these eleven regressions, we were able to convert all of the alternate metrics of IPV prevalence in our dataset to estimates of "ever any IPV." We eliminated observations based on alternate metrics of IPV which came from studies that also provided estimates of IPV based on the reference definition.

After applying crosswalks to the alternate metrics of IPV in the manner described above, we made an additional adjustment to the subset of our data that was based on only ever-partnered, currently partnered women currently married women or ever married women. To adjust these values so that they reflected IPV prevalence in the entire female population, regardless of partnered status, we multiplied estimates from these studies by the age-specific fraction of women who had ever been partnered. An updated time series was generated in GBD 2015 using MICS and DHS data in a single parameter DisMod model to reflect the most recent data on proportion of women that have ever been partnered.

After these pre-DisMod crosswalks and adjustments, a single-parameter prevalence model was run in DisMod-MR 2.1 with age mesh points at 0 14 15 20 30 40 50 60 80 & 100. A study-level fixed effect on integrand variance (z-cov) to indicate whether a study was nationally representative or not was used to account for the heterogeneity introduced by studies that are not generalizable to the entire population. This covariate was first tested as an x-cov and the coefficient indicated no systematic bias.

In addition to the lifetime exposure model as described, a 12-month exposure model was also run in DisMod-MR 2.1, with data collected and processed analogously. This 12-month exposure model was used for the IPV-abortion PAF calculation to match the exposure definition in the risk evidence.

Direct PAF for female homicides

The burden of homicides attributable to intimate partner violence was modelled as a direct PAF.

Input data fed into a single-parameter proportion DisMod-MR 2.1 model, which had age mesh points at 0 10 20 45 & 100. The model had a study-level covariate for sources just including police reported homicides. We also included a study-level fixed effect on integrand variance (z-cov) to indicate whether a study was nationally representative or not. This covariate was first tested as an x-cov and the coefficient indicated no systematic bias.

In GBD 2015, we added prevalence of binge drinking to the model as a country-level covariate, but it was dropped for GBD 2016 because it produced a non-significant coefficient.

Cumulative risk approach for PAF of HIV/AIDS due to IPV

The third and final modelling approach that we used to assess burden attributable to intimate partner violence was a cumulative risk approach to measure the burden of HIV/AIDS attributable to IPV.

The approach itself remained the same in GBD 2017, but included updated intimate partner violence exposure numbers from the DisMod-MR 2.1 model described above, as well as revised HIV incidence numbers.

From two cohort studies (Jewkes et al, Lancet 2010 & Kouyoumdijian, et al AIDS 2013) we pooled incidence rate ratio (IRR) of HIV incidence with a random effects model. As we measure burden based on deaths and prevalence, we needed to quantify attributable fractions for prevalence and death rather than incidence. To get a PAF for prevalence we needed to consider the history of exposure to IPV and the accumulated associated risk of incident HIV due to IPV, relative to the overall risk of HIV at the population level. The ratio of cumulative IPV-attributable HIV incidence to total HIV incidence was an approximation of the relevant PAF for HIV prevalence and we assumed this PAF can also be applied to mortality.

$$\frac{Cumulative\ HIV\ incidence\ due\ to\ IPV}{Cumulative\ HIV\ incidence\ overall} = \frac{1-\prod_{a=o}^{a=n}\left(1-PAF_{ay}*I_{ay}\right)}{1-\prod_{a=o}^{a=n}(1-I_{ay)}}$$

Where:

I = annual incidence rate of HIV

a = age (15-95)

y = year (1980-2016)

$$PAF_{HIV\ incidence} = \frac{[Prevalence\ of\ IPV]_{ay*}\ (IRR-1)}{[Prevalence\ of\ IPV]_{ay*}\ (IRR-1)+1}$$

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level is zero exposure to intimate partner violence, as defined above.

Relative risks

We estimate burden attributable to IPV for abortion, depressive disorders, interpersonal violence (i.e. homicide) and HIV incidence. For GBD 2016, we completed a systematic review of the literature for papers reporting relative risk of IPV and our outcomes. Suicide, which was modelled as an outcome of IPV for GBD 2015, was removed from the analysis based on the availability of relative risk literature using suicide and not attempted suicide as the outcome definition. For GBD 2017, we used the same causal evidence for relative risk as was used for GBD 2016.

For HIV, we use a pooled IRR of 1.59 (95% CI 1.3-1.94) from a random effects inverse variance weighted meta-analysis of the two available prospective studies as of date.

The relative risks for depressive disorders and suicide come came from a systematic review of longitudinal studies assessing intimate partner violence and incident diagnosed major depression. A random effects inverse variance weighted meta-analysis produced a pooled relative risk and 95% confidence interval of 1.44 (1.09, 1.92).

For the relative risk for IPV-abortion, we also performed a random effects, inverse variance meta-analysis, which produced a pooled relative risk and 95% confidence interval of 1.91 (1.15, 3.16). An important methodological note with IPV-abortion is that we must apply the pooled relative risk for abortion to the current prevalence of IPV (in the previous 12 months), rather than lifetime prevalence. This is because the case definition for the relative risk component studies was physical or sexual IPV in the past year.

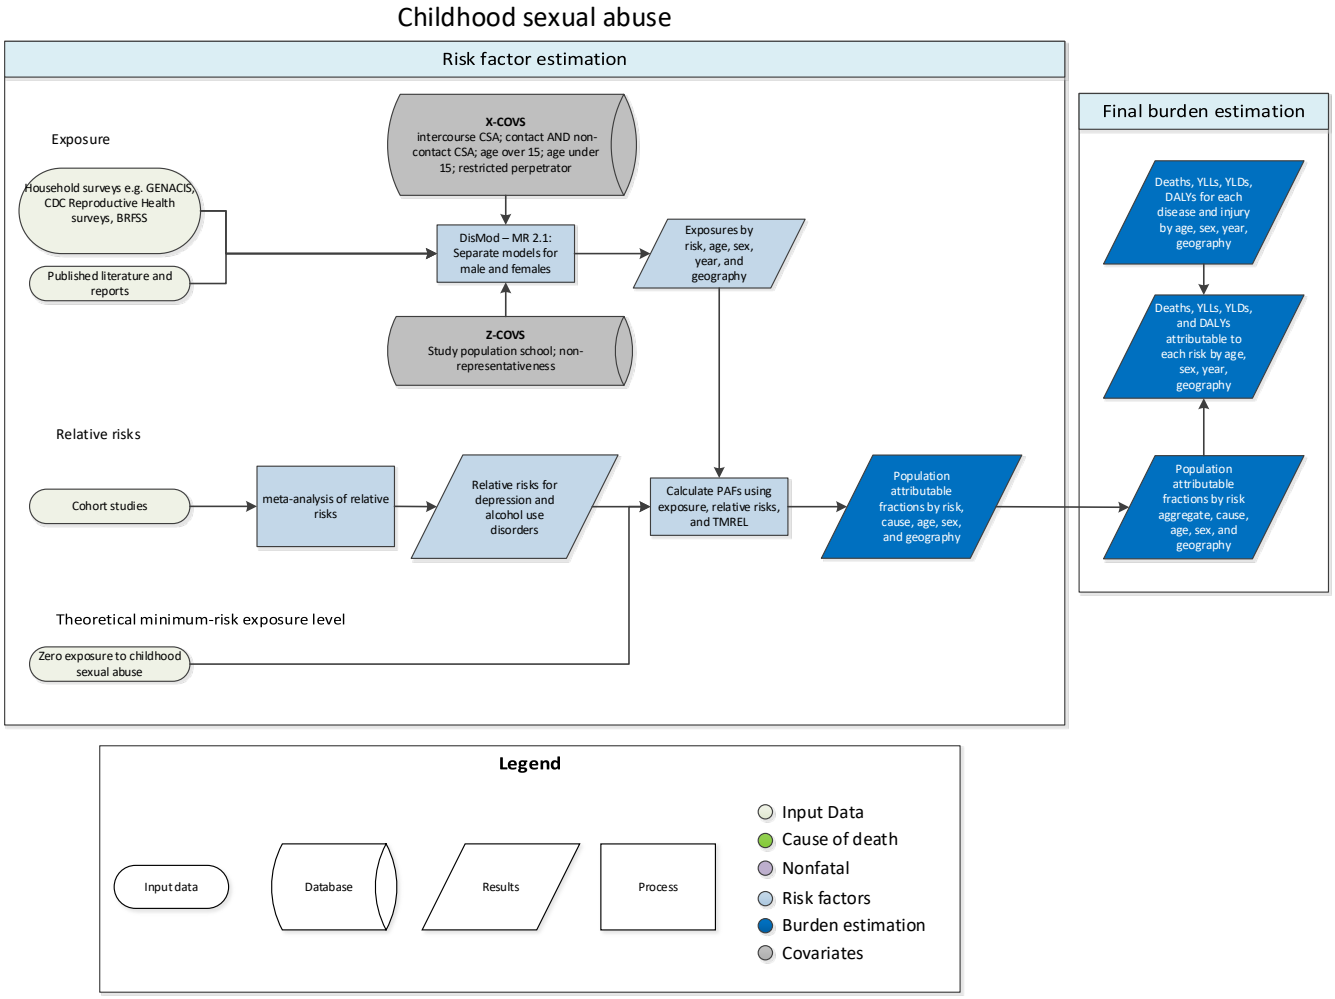
Childhood Sexual Abuse Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

The case definition for childhood sexual abuse (CSA) is ever having had the experience of intercourse or other contact abuse (i.e. fondling and other sexual touching) when aged 15 years or younger, and the perpetrator or partner was greater than five years older than the victim.

Input data

Currently, we use self-reported survey data to measure CSA prevalence, not data from Child Protection Services (CPS) or other crime data. The reliability and comprehensiveness of CPS and crime statistics varies too much geographically to warrant inclusion.

Although no systematic review of the literature was completed for GBD 2017, an updated systematic review of CSA prevalence literature was conducted for sources published between August 2015 and January 2017 during the GBD 2016 cycle. The following search terms were used:

((((("health surveys"[MeSH Terms] AND prevalence[Title/Abstract]) OR ("sentinel surveillance"[MeSH Terms] AND prevalence[Title/Abstract]) OR ("prevalence"[Title/Abstract] AND cross sectional studies[MeSH Terms])) AND (("child abuse"[MeSH Terms] OR "child abuse, sexual"[MeSH Terms]) OR ("sex offenses"[MeSH Terms] OR "child abuse, sexual"[MeSH Terms]) OR (child*[Title/Abstract] AND sexual[Title/Abstract] AND abuse[Title/Abstract]))) NOT ("comment"[Publication Type] OR "letter"[Publication Type] OR "editorial"[Publication Type]))

We supplemented with data from relevant national health surveys and violence-specific surveys. Several survey series used include the United States Behavioral Risk Factor Surveillance System, the CDC Reproductive Health Surveys, Brazil National Alcohol and Drug Survey, and the Gender, Alcohol, and Culture International Study (GENACIS).

A number of study level covariates were also extracted that were used in the modelling process to adjust for heterogeneous definitions across sources. All crosswalks and adjustments were done in DisMod-MR 2.1.

Modelling strategy

CSA prevalence was modeled as a single parameter prevalence model in DisMod-MR 2.1. CSA exposure is modeled separately for males and females because we observe little correlation between the prevalence of child abuse among females and males, and modeling both sexes together causes unreasonable estimates in countries where we only have data for one sex.

Three study-level covariates were used for alternate definitions of the violence.

- Study asked only about intercourse CSA
- Study asked about contact and non-contact CSA
- Study placed restrictions on the relationship between the perpetrator and the victim (e.g. only asked about CSA committed by a father)

We also included study-level fixed effects for varying age thresholds across studies.

- Study asked about recall for events before ages above 15 years (versus reference age threshold of 15)
- Study asked about recall for events before ages less than 15 years (versus reference age threshold of 15)

Two study-level covariate fixed effects on variance (z-cov) were also included in both the male and female models, including an indicator that the survey was not nationally representative, as well as whether the survey was administered in schools. These study-level covariates were tested as x-covs first, but we did not find coefficients which would indicate systematic bias. We have not included any national-level covariates to date due to lack of knowledge about a covariate (for which we have a time series for all GBD locations) that predicts CSA prevalence.

Theoretical minimum-risk exposure level

The theoretical minimum risk exposure level is zero exposure to contact childhood sexual abuse.

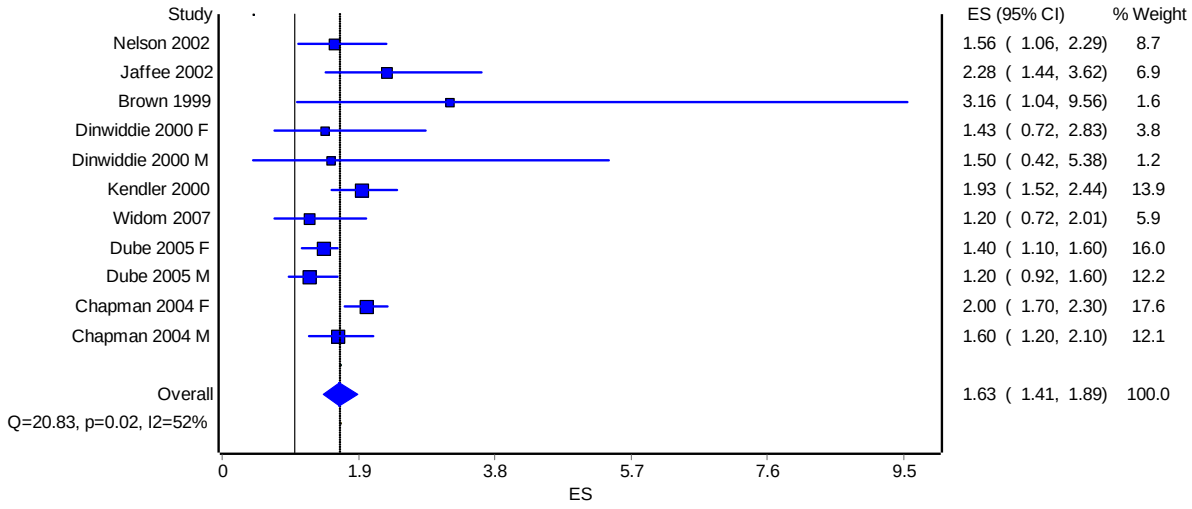
Relative risks

We estimate burden attributable to CSA for the following health outcomes: unipolar depressive disorders (major depressive disorder and dysthymia) and alcohol use disorders.

In GBD 2015, we used one twin study that compared adverse outcome risks in same-sex discordant pairs.[1] This study was deemed reliable given that environmental and contextual factors are inherently controlled for when comparing between twins, avoiding potential confounding. However, to add to the strength of the evidence for GBD 2016, we performed a systematic review and a random effects meta-analysis to produce relative risks for depressive disorders and alcohol use disorders. In a departure from GBD 2015, suicide was not used as an outcome for CSA. This decision was based on the evidence available for the relative risk of suicide given exposure to CSA – not enough studies used suicide as an outcome, but instead used attempted suicide. For GBD 2017, we used the same causal evidence as was used for GBD 2016.

The pooled relative risk figures and 95% confidence intervals were 1.63 (1.41, 1.89) for depressive disorders and 1.54 (1.19, 1.99) for alcohol use disorders. The resulting forest plots are as follows:

CSA and depressive disorders meta-analysis



CSA and alcohol use disorders meta-analysis

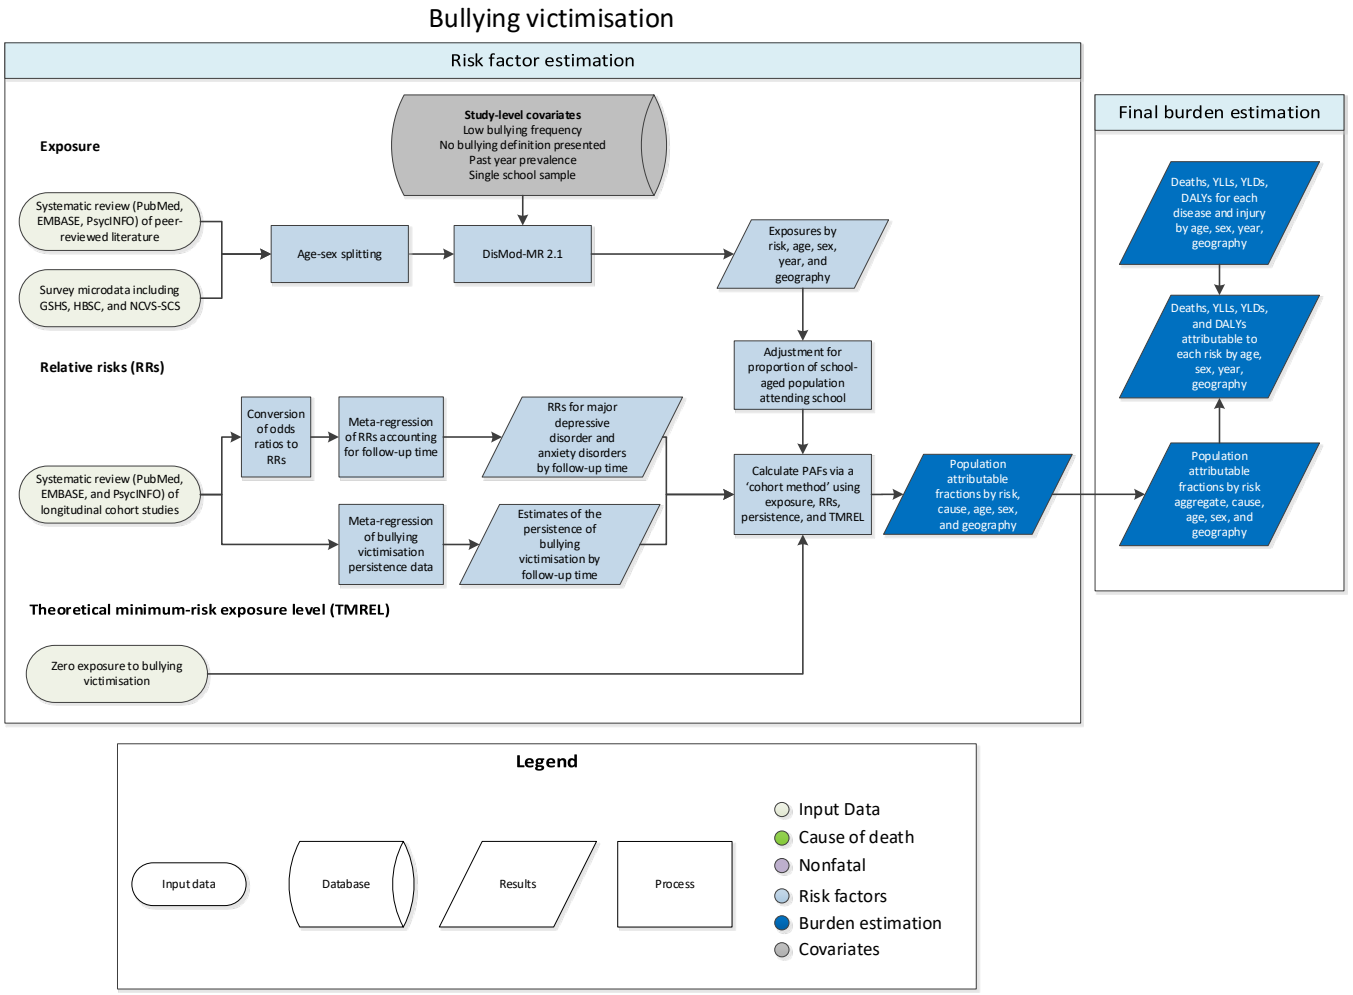
Bullying Victimisation Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Bullying victimisation is commonly conceptualised as the intentional and repeated harm of a less powerful individual by peers.[1] This differentiates bullying victimisation from disagreements, conflicts, or playful teasing. The case definition of bullying victimisation in the GBD context is 'bullying victimisation of children and adolescents attending school by peers.' This definition includes the global concept of bullying victimisation which incorporates combined estimates of subtypes such as physical, verbal, relational, and cyberbullying victimisation. It excludes abuse/harassment by siblings, intimate partners, and adults (e.g. teachers). While bullying can be experienced as either a victim or perpetrator,

perpetration (i.e. those who bully others) is not included in this definition although some victims will also be perpetrators.

Input data

In order for a study to be included, it must report the prevalence of bullying victimisation and 1) have been published since 1980, 2) ask participants about bullying victimisation in the previous year or more recently, 3) use an appropriate frequency threshold to define bullying victimisation (approximating at least once a week or greater than 'occasionally'), 4) be representative of the general population rather than a special population (e.g. ethnic minorities), and 5) report prevalence for bullying victimisation overall rather than a subtype e.g. physical bullying victimisation.

Included studies were sourced from a systematic review of three electronic databases (PubMed, EMBASE, and PsycINFO), covering the period 1980 to 2017. No restriction was set on the language of publication. GhDx was also used to source microdata from survey series meeting the above inclusion criteria. Estimates from the Global School-based Student Health Survey (GSHS), the Health Behavior in School-aged Children (HBSC), and the National Crime Victimization Survey – School Crime Supplement (NCVS-SCS) were extracted and included in the dataset.

Modelling strategy

Bullying victimisation prevalence was modelled as a single parameter prevalence model in DisMod-MR 2.1. We assumed no prevalence prior to 5 years or after 20 years of age. Four study-level covariates were included and are shown in the table below, along with their respective levels. Crosswalks for two of the covariates (low bullying frequency and no bullying definition presented) were calculated using within-study pairs of reference and non-reference estimates (n = 9 pairs and n = 3 pairs, respectively).

Covariate name	**Reference**	**Non-reference**	**Exponentiated beta**
Low bullying frequency	Optimal frequency threshold used e.g. 'frequently'	Sub-optimal frequency threshold used e.g. 'sometimes + frequently'	3.35 (3.35 – 3.35) *(n = 9 pairs)*
No bullying definition presented	Definition of bullying victimisation presented to participants	No definition of bullying victimisation presented to participants or not specified	1.12 (1.12 – 1.12) *(n = 3 pairs)*
Recall 1 year	Asked about bullying victimisation more recently than in the past year	Asked about bullying victimisation in the past year	1.47 (1.30 – 1.68)
Single school sample	Sample was a household survey or multi-school survey	Sample was from a single school	1.21 (1.01 – 2.12)

Adjustment for years of schooling

In order to better represent the prevalence of bullying victimisation, prevalence estimates were adjusted for the proportion of children and adolescents attending school by ages 5-9, 10-14, and 15-19 years by sex, location, and year. Data on the proportion of children and adolescents attending school was sourced from the online database (http://data.uis.unesco.org/) published by the United Nations Educational, Scientific, and Culture Organization (UNESCO). The data covered 18,441 country-years for

age groups 6-11, 12-14, and 15-17 years by sex. This data was modelled in ST-GPR, with average years of education as a country-level covariate, to predict the proportion of children and adolescents attending school by these age groups. This gave estimates of the proportion of children and adolescents attending school by age, sex, year, and location.

Theoretical minimum-risk exposure level

The theoretical minimum risk exposure level was assumed to be zero exposure to bullying victimisation.

Relative risks (RRs)

We estimate burden attributable to bullying victimisation for major depressive disorder and anxiety disorders. Data on the association between bullying victimisation and self-harm was also reviewed but not included due to variation in the definition of 'self-harm' and only one study looking at suicide.

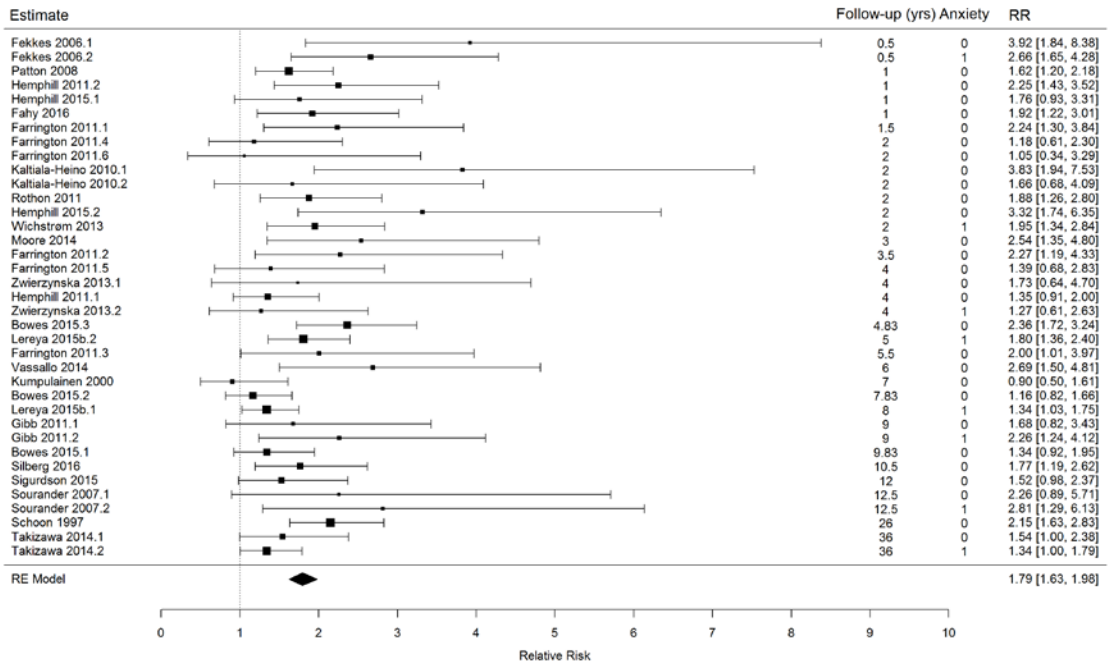
Input data for RRs

Studies reporting the prospective longitudinal association between these outcomes and bullying victimisation were sourced from a systematic review of three electronic databases (PubMed, EMBASE, and PsycINFO), covering the period 1980 to 2017. No restriction was set on the language of publication. Studies had to report RRs, ORs, or sufficient data to calculate RRs (i.e. exposed/non-exposed cases/non-cases).

Meta-analysis

The smaller number of estimates for anxiety disorders (n = 6) led to the decision to combine the major depressive disorder and anxiety disorders RR data into a single dataset. This was considered reasonable as the pooled RRs for major depressive disorder and anxiety disorders were effectively equal following an adjustment for low frequency bullying threshold studies (1.82, 95% CI: 1.62-2.04 vs 1.74, 95% CI: 1.43-2.11, respectively).

Meta-analysis of bullying victimisation and major depressive disorder/anxiety disorders



Meta-regression

A meta-regression was conducted to determine the impact of follow-up time on the relationship between bullying victimisation and major depressive disorder/anxiety disorders.

Prior to this, an initial meta-regression revealed studies with a low bullying frequency threshold reported significantly lower RRs than studies utilising the optimal threshold. Six studies reported RRs for both low and optimal bullying frequency threshold and we determined that the within-study ratios from these studies would better inform an adjustment than between-study comparisons estimated as a covariate. These ratios were pooled and then applied to the low bullying frequency threshold estimates (i.e. suboptimal estimates) prior to analysis. This process could not be done for the other characteristics (i.e. symptoms vs diagnosis or no control vs control for outcome as baseline) as there were no within-study comparisons available. In the final meta-regression, these were instead controlled for using covariates.

In the final meta-regression, estimates with a follow-up time of 25 years or more were excluded due to only data from a single cohort being available to inform the effect of follow-up time after this period. In total, 19 studies were included in the analyses.[2-20] While the meta-regression demonstrated a waning effect of time, this was not statistically significant (p = 0.093). However, the model still predicted plausible estimates of RR over time that matched our strong prior that the effect size would have to diminish over time. Time was also significant in a parsimonious model that did not include the non-significant covariates (p = 0.042).

PAF calculations

For bullying victimisation, the PAF calculations could not be determined by current prevalence and a single value for RR. This is due to the waning effect on outcomes over time (as demonstrated in the meta-regression) and because prevalence estimates were from surveys of young people reporting current bullying victimisation rather than estimates of past exposure at the time the outcomes occur (i.e. retrospective estimates).

A cohort method was subsequently developed to address this issue. The following steps are conducted for each point of estimation (i.e. by age, sex, location, and year), hereafter referred to as a 'cohort':

1. Pull current and past bullying victimisation prevalence for the cohort from the DisMod-MR 2.1 exposure model.
2. Adjust each bullying victimisation prevalence estimate for the proportion of the cohort attending school in that year.
3. Divide the cohort into proportions based on time since first exposed to bullying victimisation. This equates to the incidence of bullying victimisation and is estimated using the following formula:

$$\boldsymbol{I_k = P_k - \sum_{n=0}^{k-1} (I_n \times r_{k-n})}$$

where I represents incidence, P represents prevalence, r represents the estimate of persistence, and k represents the time between the incidence estimate and the earliest possible time of exposure in the cohort. I_k requires I_0 through to I_{k-1} to first be calculated and so we complete this process by first estimating I_0, then I_1, and so on until we have estimated incidence for the latest possible year of exposure for this cohort. The persistence estimate is based on a separate meta-regression of seven studies.[11,21-26]

4. We Map RRs to the proportions of the cohort based on the time between the point of estimation and when they were first exposed to bullying victimisation and estimate PAFs via the following formula:

$$PAF = \frac{\sum(p_t \times RR_t) + \sum p_{no\ exposure} - 1}{\sum(p_t \times RR_t) + \sum p_{no\ exposure}}$$

where *t* is the time since first exposed to bullying victimisation, *p* is the proportion of the cohort first exposed to bullying victimisation at time *t* or the proportion not exposed to bullying victimisation, and *RR* is the relative risk for depressive and anxiety disorders given *t*.

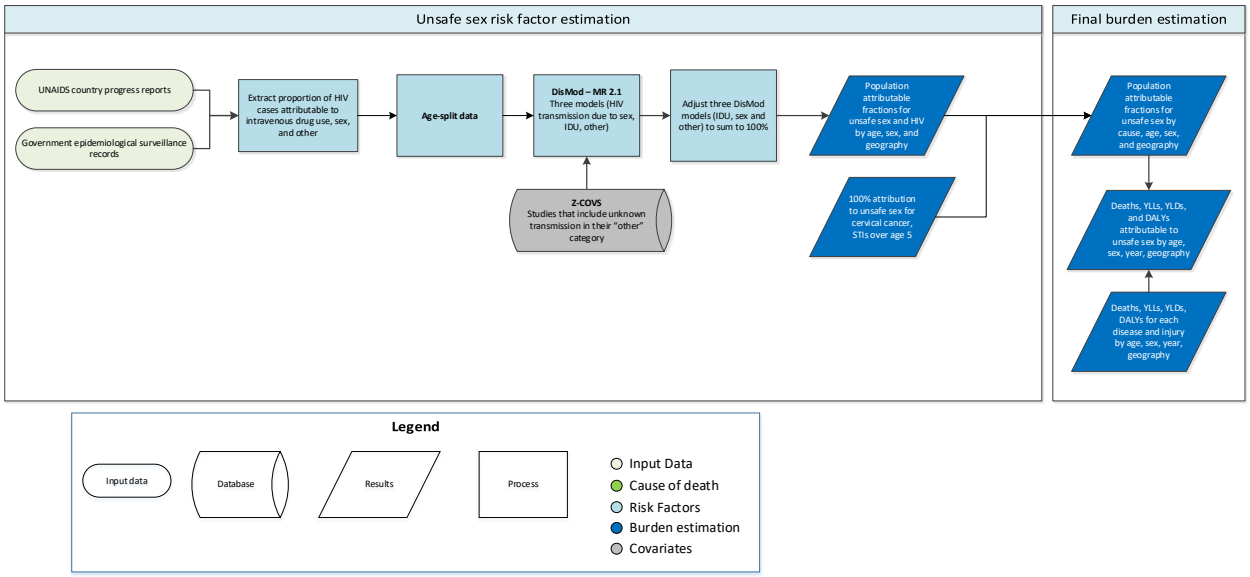
Unsafe Sex Capstone Appendix

Flowchart



Input data & methodological summary

Case definition and summary of GBD approach

Unsafe sex is defined as the risk of disease due to sexual transmission. The outcomes associated with unsafe sex that we estimate for GBD include HIV, cervical cancer, and all sexually transmitted diseases (STDs) except for those in neonates from vertical transmission, including HIV, opthalmia neonatorum and neonatal syphilis. We assume 100% of cervical cancer and STDs are attributable to unsafe sex and model the proportion of HIV incidence occurring through sexual transmission to estimate the attributable burden for HIV due to unsafe sex.

Input data

To be used in our models, sources must report HIV cases attributable to various modes of transmission. We screened all UNAIDS country progress reports and searched government epidemiological surveillance records for these data. The primary data sources we used were UNAIDS, the European CDC, and the US CDC.

We excluded all extractions where the "other" category for HIV transmissions accounted for greater than 25 percent of all cases. We believe that such high proportions raise concerns about the quality of reporting.

Modelling strategy

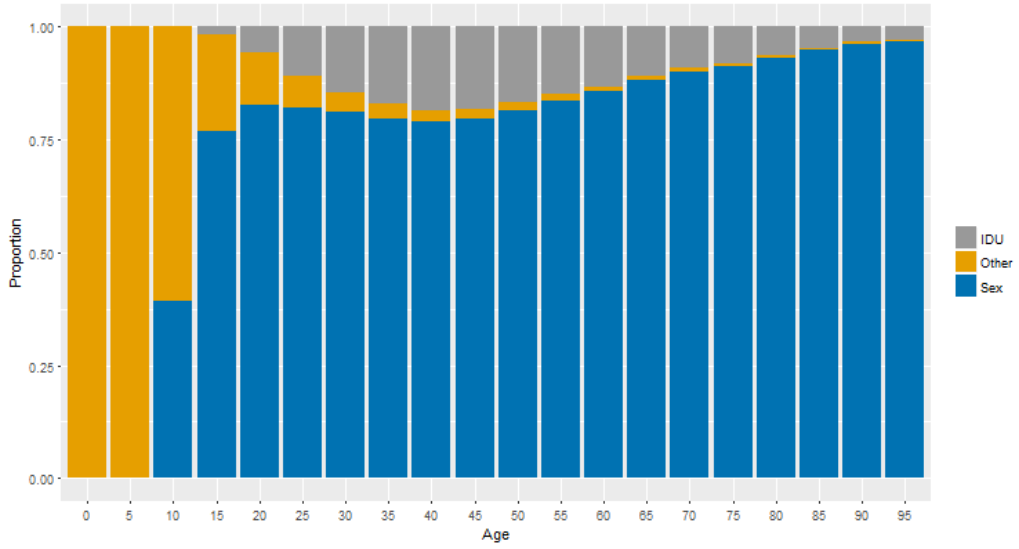
We model the proportion of HIV cases attributable to unsafe sex. To do this we collect and clean data, run three DisMod models (HIV attributable to sex, HIV attributable to injection drug use, HIV

attributable to other routes of transmission), adjust results of the three DisMod models to sum to one, and prepare PAFs.

All of the DisMod models included a study-level covariate fixed effect on integrand variance (z-cov) for sources that include cases of unknown transmission in their "other" category. We assumed that the inclusion of unknown cases in the other category would impact the uncertainty around the point estimates. No country level covariates were included in the models. We tested an injection drug use covariate, an opioid use covariate in the proportion HIV due to drug use model, but found no significant coefficients so excluded them from the final model.

A new approach was introduced for GBD 2016, and used again for GBD 2017, to inform an age-pattern in these HIV transmission models. All-age data points represent the majority of the available data, so we derived an age-pattern for the HIV-IDU transmission model from the age-pattern present in the GBD 2017 population attributable fraction for hepatitis B attributable to intravenous drug use. Assuming the proportion of HIV due to other is constant over time, the age-pattern for the proportion of HIV due to sex was set to be the complement to 1 of the age-pattern for the proportion of HIV due to IDU. The all-age data were split according to these age-patterns, and the three HIV transmission DisMod models were run on the age-split data. Additional priors were set to inform an age-pattern: zero proportion HIV transmission due to IDU before age 15, zero proportion HIV transmission due to sex before age 10, and 100% transmission due to other before age 10. The results from these HIV transmission models were adjusted to sum to 100% for a given country-year-age-sex group at each of 1,000 draws.

Squeezed global HIV transmission models by age (females, 2016):



Theoretical minimum-risk exposure level

The theoretical minimum level used for unsafe sex is the absence of disease transmission due to sexual contact.

Population attributable fraction calculations

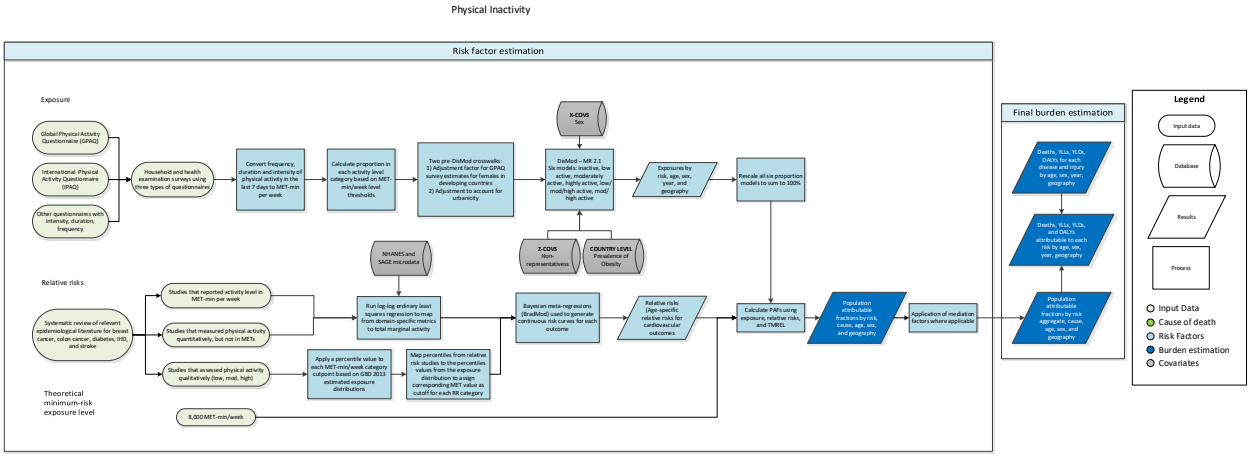
The outcomes associated with unsafe sex that we report on include HIV, cervical cancer, and all sexually transmitted diseases (STDs) except for those in neonates from vertical transmission, including HIV, opthalmia neonatorum and neonatal syphilis.

Based on evidence in the literature, we attribute 100% of cervical cancer to unsafe sex. These sources state that HPV infection is necessary for cervical cancer to develop and that HPV is only spread through sexual contact. The proportion of STDs attributable to unsafe sex is also 100%.

For HIV, the results from the single parameter proportion DisMod model for HIV transmission due to sex were used directly as the population attributable fraction.

Low Physical Activity Capstone Appendix

Flowchart



Input data and methodological summary

Exposure

Case definition

We measure physical activity performed by adults greater than or equal to 25 years of age, for durations of at least ten minutes at a time, across all domains of life (leisure/recreation, work/household and transport). We use frequency, duration and intensity of activity to calculate total metabolic equivalent-minutes per week. MET (Metabolic Equivalent) is the ratio of the working metabolic rate to the resting metabolic rate. One MET is equivalent to 1 kcal/kg/hour and is equal to the energy cost of sitting quietly. A MET is also defined as the oxygen uptake in ml/kg/min with one MET equal to the oxygen cost of sitting quietly, around 3.5 ml/kl/min.

Input data

We included surveys of the general adult population that captured self-reported physical activity in all domains of life (leisure/recreation, work/household and transport), where random sampling was used.

Data were primarily derived from two standardised questionnaires: The Global Physical Activity Questionnaire (GPAQ) and the International Physical Activity Questionnaire (IPAQ), although we included other survey instruments that asked about intensity, frequency and duration of physical activities performed across all activity domains.

Due to a lack of a consistent relationship on the individual level between activity performed in each domain and total activity, we were not able to use studies that included only recreational/leisure activities.

Physical activity level is categorised by total MET-minutes per week using four categories based on rounded values closest to the quartiles of the global distribution of total MET-minutes/week. The lower limit for the Level 1 category (600 MET-min/week) is the recommended minimum amount of physical activity to get any health benefit. We used four categories with higher thresholds rather than the GPAQ

and IPAQ recommended 3 categories to better capture any additional protective effects from higher activity levels.

- Level 0: < 600 MET-min/week (inactive)
- Level 1: 600-3999 MET-min/week (low-active)
- Level 2: 4000-7,999 MET-min/week (moderately-active)
- Level 3: ≥ 8,000 MET-min/week (highly active)

The GHDx was used to locate all surveys that use the GPAQ or IPAQ questionnaire. Although there were many other surveys that focused specifically on leisure activity, we were unable to use these sources because they did not comprise all three domains (work, transport and leisure). In addition, we excluded any surveys that did not report frequency, duration, and intensity of activity.

Modelling strategy

DisMod modelling

For this round of the GBD, we have chosen to separately model all of the GPAQ data separately from the IPAQ data. We then estimated the proportion of each country/year/age/sex subpopulation in each of the above four activity levels using 12 separate Dismod models (one for each data source). We use six categories of physical activity prevalence rather than four to accommodate the different MET-minute/week cutoffs presented in tabulated data sources where individual unit record data was not available. Since the accepted threshold/definition for inactivity is consistently <600 MET-minutes/week, the vast majority of tabulated data was broken down into proportion inactive (model A) and proportion low, moderate or highly active (model B).

	Label	MET-min/week	Name of sequelae in online visualisation tool
A	inactive	<600	Physical inactivity and low physical activity, inactive
B	low/moderately/highly active	≥600	Physical inactivity and low physical activity, low/moderately/highly active
C	low active	600-3999	Physical inactivity and low physical activity, low active
D	moderately/highly active	>4000	Physical inactivity and low physical activity, moderately/highly active
E	moderately active	4000-7999	Physical inactivity and low physical activity, moderately active
F	highly active	≥8,000	Physical inactivity and low physical activity, highly active

These models have mesh points at 0 15 25 35 45 55 65 75 85 100, and a study-level fixed effect on integrand variance (Z-cov) for whether a study was nationally representative or not, to account for the heterogeneity introduced boy studies that are not generalizable to the entire population. They also have national level fixed effects on prevalence of obesity.

After DisMod, we rescale each of the 6 models specific to each data source so that the proportions sum to one. Since we have the most data for models A and B, we rescale the sum of the proportion in each category to be equal to one. Next we rescale the sum of model C and D to be equal to the rescaled value from model B. Then we rescale the sum of models E and F to be equal to the rescaled value from model D. After these three rescales we are left with a proportion for each of the four categories that all sum to

1. Scaled results for each data source are then hybridised to produce only one set of results for the prevalence of the four categories of physical activity.

Similar to the previous round, we have directly estimated total MET-minutes per week globally. Although, this year we made use of two specific machine learning algorithms (Random Forest & XGBoost) that were trained using data that could characterise the relationship between total MET-mins/week and each of the categorical prevalences of physical activity. This resulted in country-year-age-sex specific estimates of total physical activity in the form of MET-minutes per week.

Utilising microdata on total MET-mins per week from individual-level surveys, we characterised the distribution of activity level at the population level. We then used an ensemble approach to distribution fitting, borrowing characteristics from individual distributions to tailor a unique distribution to fit the data using a weighting scheme. We characterised the standard deviation of each population's activity through a linear regression that captured the relationship between standard deviation and mean activity levels in nationally representative IPAQ surveys:

$$ln\,(Standard\ deviation) = \beta_0 + \beta_1 \times ln\,(Mean_i)$$

We then applied the coefficients of this regression to the outputs of our estimate of total MET-minutes per week regression outputs to calculate the standard deviation by country, year, age, and sex.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level for physical inactivity is 3000-4500 MET-min per week, which was calculated as the exposure at which minimal deaths across outcomes occurred.[3]

Relative risks

We used a recently published dose-response meta-analysis of prospective cohort studies to estimate the effect size of the change in physical activity level on breast cancer, colon cancer, diabetes, ischemic heart disease and ischemic stroke.[3]

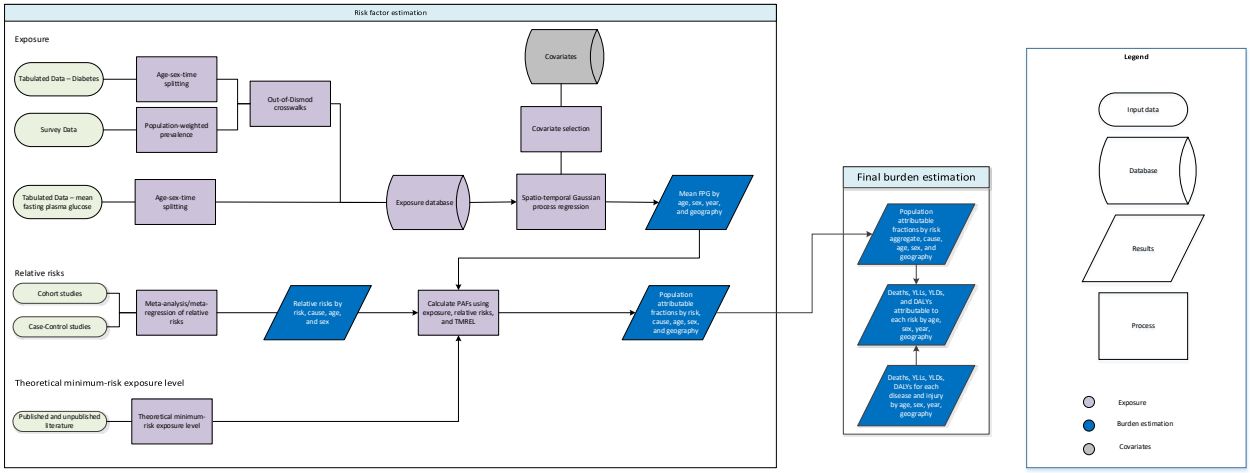
High Fasting Plasma Glucose Capstone Appendix

Flowchart



Case definition

High fasting plasma glucose (FPG) is measured as the mean FPG in a population, where FPG is a continuous exposure in units of mmol/L.

Data seeking

Exposure

We did not conduct a systematic review for FPG in GBD 2017. However, we included data sources found in the systematic review for diabetes. Please see the diabetes mellitus appendix in *Global, regional, and national incidence, prevalence, and years lived with disability for 354 diseases and injuries for 195 countries, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017* for more information on data sources found through those efforts.

Data inputs

Data inputs come from 3 sources:

- Estimates of mean FPG in a representative population
- Individual-level data of fasting plasma glucose measured from surveys
- Estimates of diabetes prevalence in a representative population

Data sources that did not report mean FPG or prevalence of diabetes are excluded from analysis. When a study reported both mean fasting plasma glucose (FPG) and prevalence of diabetes, we use the mean FPG for exposure estimates. Where possible, individual-level data supersede any data described in a study. Individual-level data are aggregated to produce estimates for each 5-year age group, sex, location, and year of a survey.

Data processing

We perform several processing steps to the data in order to address sampling and measurement inconsistencies that will ensure the data are comparable.

1. *Small sample size*
   Estimates in a sex and age group with a sample size <30 persons is considered a small sample size. In order to avoid small sample size problems that may bias estimates, data are collapsed into the next age group in the same study till the sample size reach at least 30 persons. The intent of collapsing the data is to preserve as much granularity between age groups as possible. If the entire study sample consists of <30 persons and did not include a population-weight, the study is excluded from the modelling process.

2. *Time, Age, and Sex Splitting*
   For more details on how datapoints on mean FPG was processed, please see the diabetes mellitus appendix in *Global, regional, and national incidence, prevalence, and years lived with disability for 354 diseases and injuries for 195 countries, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017*.

3. *Crosswalks*
   We predicted mean FPG from diabetes prevalence using an ensemble distribution. We characterized the distribution of FPG using individual-level data. Details on the ensemble distribution can be found elsewhere in the Appendix. Before predicting mean FPG from prevalence of diabetes, we ensured that the prevalence of diabetes was based on the reference case definition: fasting plasma glucose (FPG) >126 mg/dL (7 mmol/L) or on treatment. For more details on how the case-definition crosswalk is conducted, please see the diabetes mellitus appendix in *Global, regional, and national incidence, prevalence, and years lived with disability for 354 diseases and injuries for 195 countries, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017*.

Exposure modelling

Exposure estimates are produced for every year between 1980 to 2017 for each national and subnational location, sex, and for each 5-year age group starting from 25 years. As in GBD 2016, we used a Spatio-Temporal Gaussian Process Regression (ST-GPR) framework to model the mean fasting plasma glucose at the location-, year-, age-, and sex- level. Updates to the ST-GR modelling framework for GBD 2017 are detailed elsewhere in the Appendix.

Fasting plasma glucose is frequently tested or reported in surveys aiming at assessing the prevalence of diabetes mellitus. In these surveys, the case definition of diabetes may include both a glucose test and questions about treatment for diabetes. People with positive history of diabetes treatment may be excluded from the FPG test. Thus, the mean FPG in these surveys would not represent the mean FPG in the entire population. To address this limitation, using the data from the surveys reporting mean FPG in the entire population, we estimated a regression-based correction factor and adjusted the mean FPG to account for diabetics in the population. We also use an ensemble distribution to characterize the distribution of FPG in the population and estimate the standard deviation based on mean FPG and prevalence of diabetics from the non-fatal diabetes mellitus model.

To inform our estimates in data-sparse countries, we systematically tested a range of covariates and selected two covariates based on AIC and adjusted R^2. These included prevalence of obesity and lag-distributed income per capita (LDI).

Mean FPG iss estimated using a mixed-effects linear regression, run separately by sex:

$$\text{logit}\left(\text{FPG}_{c,a,t}\right) = \beta_0 + \beta_1 \log(\text{LDI})_{c,t} + \beta_2 p_{\text{overweight}_{c,a,t}} + \sum_{k=2}^{16} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_c + \epsilon_{c,a,t}$$

where $\log(\text{LDI})_{c,t}$ is the log of the lag-distributed income, $p_{\text{overweight}_{c,a,t}}$ is the prevalence of overweight, $I_{A[a]}$ is an indicator variable for a fixed effect on a given 5-year age group, and α_s α_r α_c are random effects at the super-region, region, and country level, respectively. The estimates were then propagated through the ST-GPR framework to obtain 1000 draws for each location, year, age, and sex.

Theoretical minimum-risk exposure level

The theoretical minimum-risk exposure level (TMREL) for FPG is 4.5-5.4 mmol/L. This was calculated by taking the person-year weighted average of the levels of FPG that were associated with the lowest risk of mortality in the pooled analyses of prospective cohort studies.[1]

Relative risks

We estimate 15 outcomes due to high fasting plasma glucose (continuous risk) or diabetes (categorical risk).

Risk	Outcome
Fasting plasma glucose	Ischemic heart disease
Fasting plasma glucose	Ischemic stroke
Fasting plasma glucose	Subarachnoid hemorrhage
Fasting plasma glucose	Intracerebral hemorrhage
Fasting plasma glucose	Peripheral vascular disease
Fasting plasma glucose	Type 1 diabetes
Fasting plasma glucose	Type 2 diabetes
Diabetes mellitus	Drug-resistant tuberculosis
Diabetes mellitus	Drug-susceptible tuberculosis
Diabetes mellitus	Multidrug-resistant tuberculosis without extensive drug resistance
Diabetes mellitus	Extensively drug-resistant tuberculosis

Relative risks for High Fasting Plasma Glucose (continuous risk)

In GBD 2017, diabetes was further split into diabetes type 1 and diabetes type 2, and hemorrhagic stroke was further split into subarachnoid hemorrhage and intracerebral hemorrhage.

Relative risks (RR) were obtained from dose-response meta-analysis of prospective cohort studies. Please see the citation list for a full list of studies that are utilized. For cardiovascular outcomes, we estimated age-specific RRs using DisMod-MR 2.1 with log (RR) as the dependent variable and median age at event as the independent variable with an intercept at age 110. Morbidity and mortality directly caused by diabetes type 1 and diabetes type 2 is considered directly attributable to FPG.

Relative risks for Diabetes mellitus (Categorical risk)

Relative risks were obtained from meta-analysis of cohort studies. Please see the citation list for a full list of studies that are utilized.

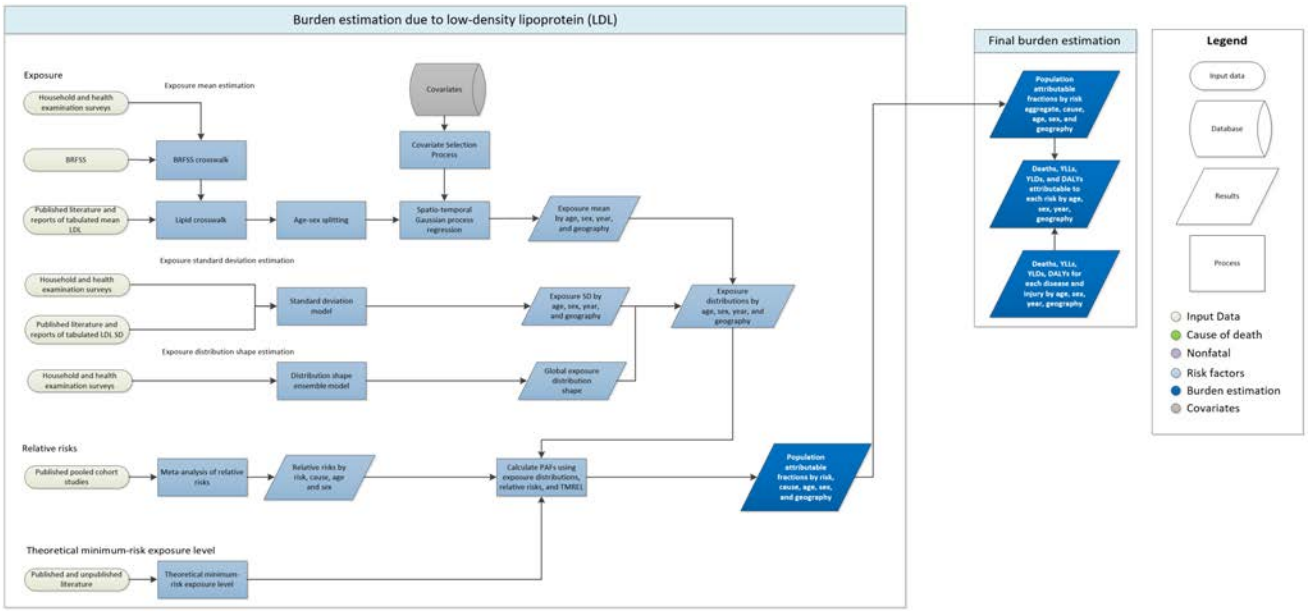
High LDL Cholesterol Capstone Appendix

Flowchart



Input Data & Methodological Summary

Exposure

Case Definition

In the GBD 2016 study, we estimated burden attributable to total cholesterol. For GBD 2017, we modelled blood concentration of low-density lipoprotein (LDL) in units of mmol/L.

Input Data

We utilized data on blood low-density lipoprotein from literature and from household survey microdata and reports. Please see the appendix for a full list of included sources. For the GBD 2016 study, we carried out an updated systematic review for total cholesterol (TC), drawing from the GHDx and Medline via PubMed. For GBD 2017, we reviewed all data sources in our database that reported data on total cholesterol and re-extracted LDL data when it was available. Data on high-density lipoprotein (HDL) and triglycerides (TGL) were also extracted when available.

Inclusion Criteria

Studies were included if they were population-based and measured total low-density lipoprotein using a blood test or calculated using the Friedewald equation. We assumed the data is representative of the location if the geography was not related to the diseases and if it is not an outlier compared to other data in the country or region.

Outliers

Data was utilized in the modeling process unless an assessment of data strongly suggested that the data

was biased. A candidate source was excluded if the quality of study did not warrant a valid estimate because of selection (non-representative populations) or if the study did not provide methodological details for evaluation. In a small number of cases, data point was considered to be an outlier candidate if the level was implausibly low or high based on expert judgement and other country data.

Data Extraction

Where possible, individual level data on LDL estimates were extracted from survey microdata and these were collapsed across demographic groupings to produce mean estimates in the standard GBD 5-year age-sex groups. If microdata were unavailable, information from survey reports or from literature were extracted along with any available measure of uncertainty including standard error, uncertainty intervals, and sample size. Standard deviations were also extracted. Where LDL was reported split out by groups other than age, sex, location, and year (eg, by diabetes status), a weighted mean was calculated.

Lipid crosswalk

Total cholesterol consists of three major components: LDL, HDL, and triglycerides. LDL is often calculated for an individual using the Friedewald equation, shown below:

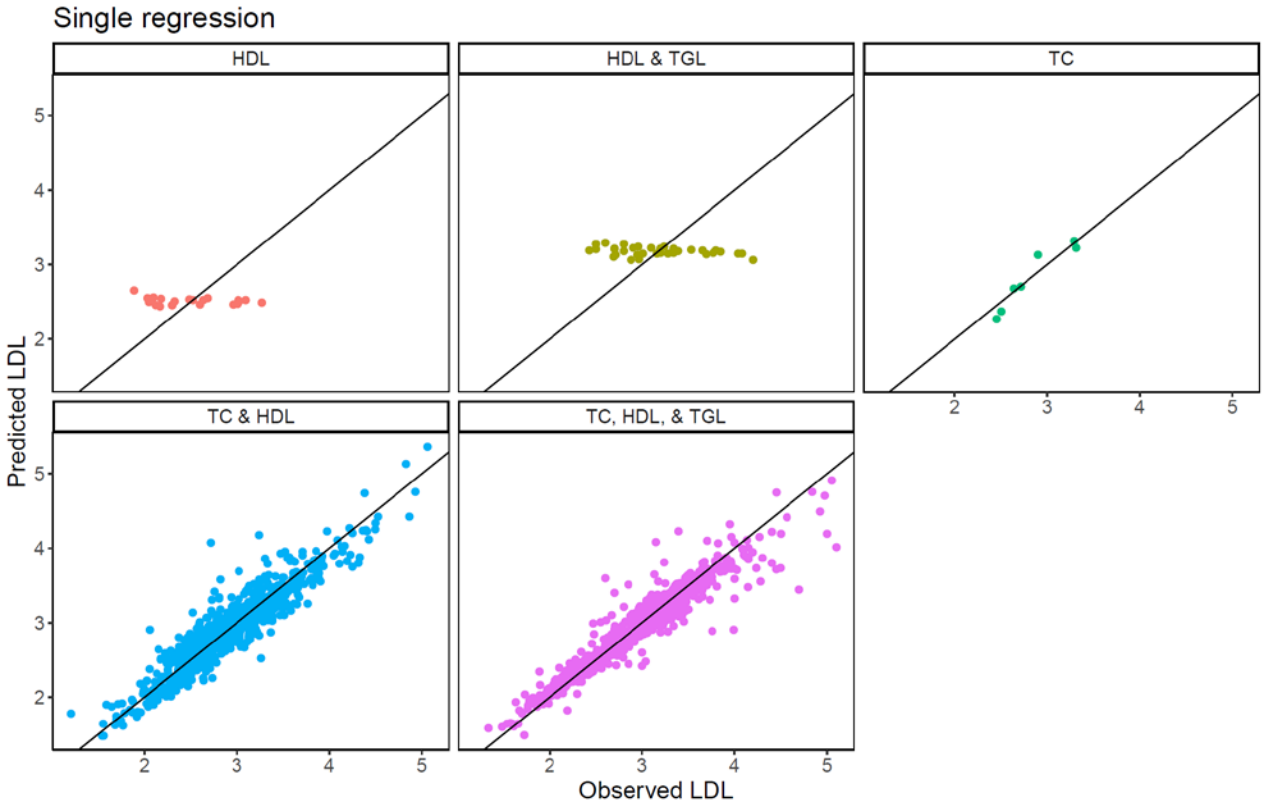
$$LDL = TC - \left(HDL + \frac{TGL}{2.2}\right)$$

We utilized this relationship at the individual level to impute the mean LDL for a study population when only data on total cholesterol, HDL, and TGL were available. Because studies report different combinations of TC, HDL, and TGL, we constructed a single regression to utilize al available data to evaluate the relationship between each lipid and LDL at the population level. We used the following regression:

$$LDL = ind_{tc}\beta_1 TC - \left(ind_{hdl}\beta_2 HDL + ind_{tgl}\beta_3 TGL\right) + \sum \alpha_l I_l$$

Where ind_{tc}, ind_{hdl}, and ind_{tgl} are indicator variables for whether data is available for a given lipid, I_l is an indicator variable a given set of available lipids l. α_l is a unique intercept for each set of available lipids. For example, for sources that only reported TC and HDL, $\alpha_{l=TC,HDL}$ should account for the missing lipid data, ie, TGL. The form of this regression allows us to estimate the betas for each lipid using all available data. As a sensitivity analysis, we also ran separate regressions for each set of available lipids and found that the single regression method had much lower root-mean squared error. A comparison of the observed vs predicted LDL for each set of available lipids is shown in Figure 1. We found almost no relationship between LDL and HDL or TGL when TC was not available, so only studies that reported TC were crosswalked to LDL.

Figure 1. Results of the lipid crosswalk using a single regression method



Incorporating United States prevalence data

Survey reports and literature often report information only about the prevalence, but not the level, of hypercholesterolemia in the population studied. These sources were not used to model LDL, with the exception of data from the Behavioral Risk Factors Surveillance System (BRFSS) because of the availability of a similarly structured exam survey covering the identical population (NHANES). BRFSS is a telephone survey conducted in the United States for all counties. It collects self-reported diagnosis of hypercholesterolemia. These self-reported values of prevalence of raised total cholesterol in each age group, sex, US state, and year were used to predict a mean total cholesterol for the same strata with a regression using data from the National Health and Nutrition Examination Survey, a nationally representative health examination survey of the US adult population. The regression was:

$$\mathrm{TC}_{\mathrm{l,a,t,s}} = \beta_0 + \beta_1 \mathrm{prev}_{\mathrm{l,a,t,s}}$$

where $\mathrm{TC}_{\mathrm{l,a,t,s}}$ is the location, age, time, and sex specific mean total cholesterol and $\mathrm{prev}_{\mathrm{l,a,t,s}}$ is the location, age, time, and sex specific prevalence of raised total cholesterol. The coefficients for both models are reported in Table 1.

Table 2. Coefficients in the sex-specific US states TC prediction models

Term	Male model	Female model
Intercept	4.23	4.36
Prevalence	6.25	5.22

Out of sample RMSE was used to quantify the predictive validity of the model. The regression was repeated 10 times for each sex, each time randomly holding out 20% of the data. The RMSEs from each holdout analysis were averaged to get the average out of sample RMSE. The results of this holdout analysis are reported in Table 2. Total cholesterol estimates were crosswalked to LDL using the lipid crosswalk reported above.

Table 3. Out of sample RMSEs of the sex-specific US states TC prediction models

	Male model	Female model
Out of sample RMSE	0.21 mmol/L	0.20 mmol/L

Age and Sex Splitting

Prior to modeling, data provided in age groups wider than the GBD 5-year age groups were processed using the approach outlined in Ng et al.[2] Briefly, age-sex patterns were identified using person-level microdata (58 sources), and estimate age-sex specific levels of total cholesterol from aggregated results reported in published literature or survey reports. In order to incorporate uncertainty into this process and borrow strength across age groups when constructing the age-sex pattern, we used a model with auto-regression on the change in mean LDL over age groups:

$$\mu_a = \mu_{a-1} + \omega_a$$
$$\omega_a \sim N(\omega_{a-1}, \tau)$$

Where μ_a is the mean predicted value for age group *a*, μ_{a-1} is the mean predicted value for the age group previous to age group *a*, ω_a is the difference in mean between age group *a* and age group *a-1*, ω_{a-1} is the difference between age group *a-1* and age group *a-2*, and τ is a user-input prior on how quickly the mean LDL changes for each unit increase in age. We used a τ of 0.09 mmol/L for this model. Draws of the age-sex pattern were combined with draws of the input data needing to be split in order to calculate the new variance of age-sex split data points.

Modeling

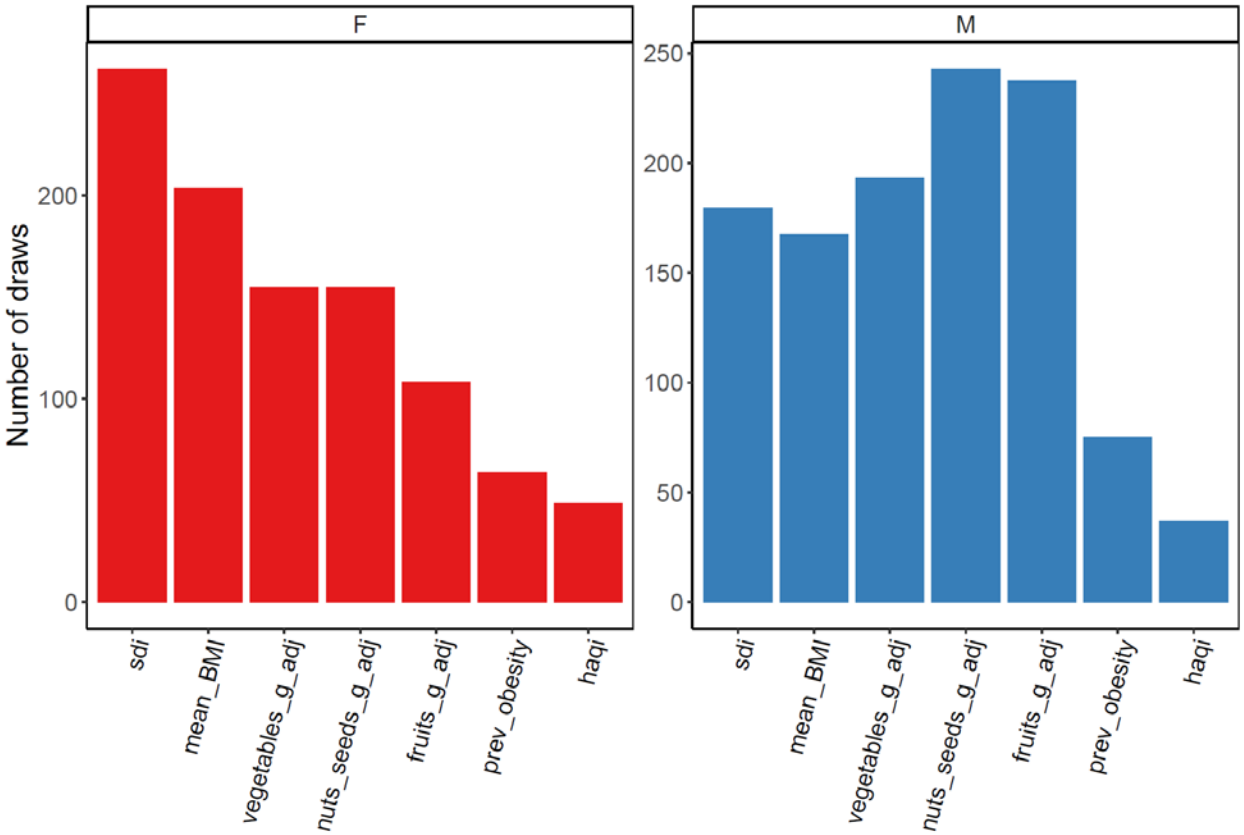
Exposure estimates were produced from 1980 to 2017 for each national and subnational location, sex, and for each 5-year age group starting from 25+. As in GBD 2016, we used a Spatio-Temporal Gaussian Process Regression (ST-GPR) framework to model the mean LDL at the location-, year-, age-, sex- level. Updates to the ST-GR modeling framework for GBD 2017 are detailed in the appendix.

Covariate selection

The first step of the ST-GPR framework requires the creation of a linear model for predicting LDL the location-, year-, age-, sex- level. Covariates for this model were selected in two stages. First a list of

variables with an expected causal relationship with LDL was created based on significant association found within high-quality prospective cohort studies reported in the published scientific literature. The second stage in covariate selection was to test the predictive validity of every possible combination of covariates in the linear model, given the covariates selected above. This was done separately for each sex. Predictive validity was measured with out of sample root-mean-squared error.
In GBD 2016, the linear model with the lowest root-mean squared error for each sex was then used in the ST-GPR model. In GBD 2017, we used an ensemble model of the 50 models with the lowest root-mean squared error for each sex. This allows us to utilize covariate information from many plausible linear mixed-effects models. The 50 models were each used to predict the mean LDL for every age, sex, location, and year, and the inverse-RMSE-weighted average of this set of 50 predictions was used as the linear prior. The relative weight in 'draws' contributed by each covariate is plotted by sex in Figure 2.

Figure 2. Results of the ensemble linear model covariate selection



Methodological updates to ST-GPR are reported above. The result of the ST-GPR model are estimates of the mean LDL for each age, sex, location, and year.

Estimate of standard deviation

The standard deviation of LDL within a population was estimated for each national and subnational location, sex, and 5-year age group starting from age 25 using the standard deviation from person-level and some tabulated data sources. Person-level microdata accounted for 3009 of the total 4001 rows of data on standard deviation. The remaining 992 rows came from tabulated data. Tabulated data was only used to model standard deviation if it was sex and 5-year age group specific and reported a population standard deviation LDL. The LDL standard deviation function was estimated using a linear regression:

$$\log(\mathrm{SD}_{c,a,t,s}) = \beta_0 + \beta_1 \log(\mathrm{mean\_LDL}_{c,a,t,s}) + \beta_4 \mathrm{sex} + \sum_{k=2}^{16} \beta_k \mathrm{I}_{A[a]}$$

where $\mathrm{mean\_LDL}_{c,a,t,s}$ is the country, age, time, and sex specific mean LDL estimate from ST-GPR, and $\mathrm{I}_{A[a]}$ is a dummy variable for a fixed effect on a given 5-year age group,.

Distribution shape modelling

The shape of the distribution of LDL was estimated using all available person-level microdata sources, which was a subset of the input data into the modelling process. The distribution shape modelling framework for GBD 2017 is detailed in the appendix. Briefly, an ensemble distribution created from a weighted average of distribution families was fit for each individual microdata source, separately by sex. The weights for the distribution families for each individual source were then averaged and weighted to create a global ensemble distribution for each sex.

Theoretical minimum-risk exposure level

A Meta-analysis of randomized trials has shown that outcomes can be improved even at low levels of LDL-cholesterol, below 1.3 mmol/l.[3] Recent studies of PCSK-9 inhibitors support these results.[4] We therefore used a TMREL with a uniform distribution between 0.7-1.3 mmol/l.

Relative risks

After a systematic search, we were unable to find relative risks for LDL that were reported by age and level of LDL. Given this evidence that the relative risks for LDL and TC are very similar[5] and the strong linear correlation between TC and LDL at the individual level, we used relative risks reported for TC to approximate the relative risks for LDL. We used Dismod-MR 2.1 to pool effect sizes from included studies and generate a dose-response curve for each of the outcomes associated with LDL. The tool enabled us to incorporate random effects across studies and include data with different age ranges. RRs were used universally for all countries and produce RRs with uncertainty and covariance across ages, taking into account the uncertainty of the data points. As in GBD 2016, RRs for IHD and ischemic stroke are obtained from meta-regressions of pooled epidemiological studies: the Asia Pacific Cohort Studies Collaboration (APCSC) and the Prospective Studies Collaboration (PSC).[6] RRs for IHD were modeled with log (RR) as the dependent variable and median age at event as the independent variable with an age intercept (RR equals 1) at age 110. For LDL and ischemic stroke, a similar approach was used, except that there was no age intercept at age 110, due to the fact that there was no statistically significant

relationship between LDL and stroke after age 70 with a mean RR less than one. We assumed that there is not a protective effect of LDL and therefore did not include an RR for ages 80+.

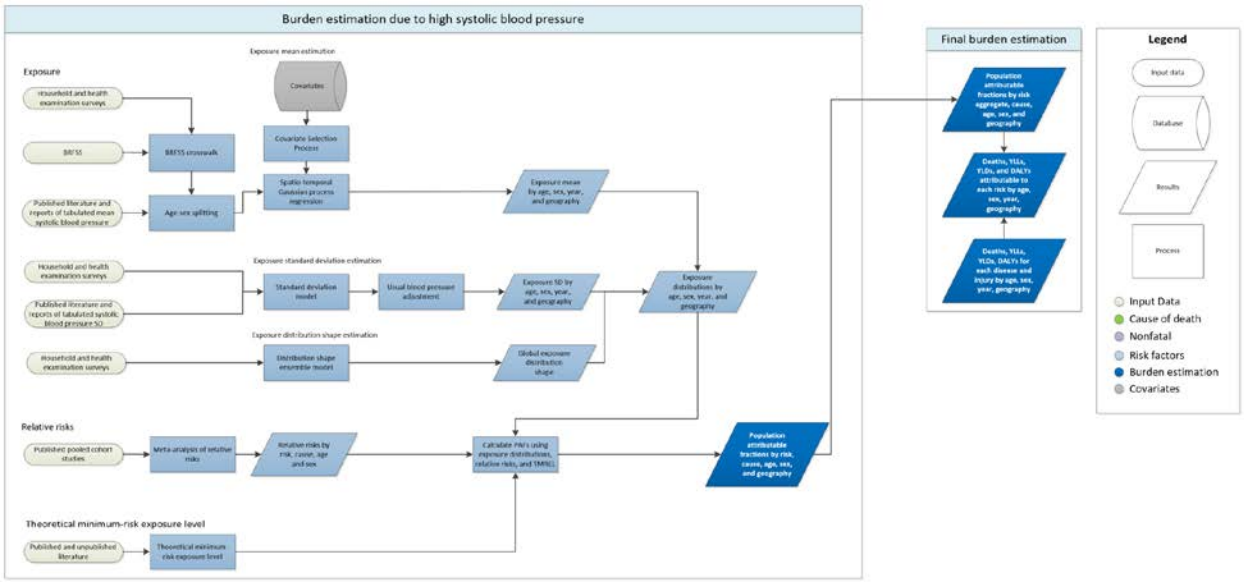
High Systolic Blood Pressure Capstone Appendix

Flowchart



Input Data & Methodological Summary

Exposure

Case Definition

Brachial systolic blood pressure in mmHg.

Input Data

We utilised data on mean systolic blood pressure from literature and from household survey microdata and reports (e.g. STEPS, NHANES). Please see the appendix for a full list of included sources. For GBD 2017, we did not carry out a systematic review of the literature for new data. In total, we have utilised 934 sources corresponding to 49,690 unique data points.

Inclusion Criteria

Studies were included if they were population-based and measured systolic blood pressure using a blood test. We assumed the data is representative of the location if the geography was not selected because it was related to the diseases.

Outliers

Data was utilised in the modelling process unless an assessment of data strongly suggested that the data was biased. A candidate source was excluded if the quality of study did not warrant a valid estimate because of selection (non-representative populations) or if the study did not provide methodological details for evaluation. In a small number of cases, a data point was considered to be an outlier candidate if the level was implausibly low or high based on expert judgement and data from other country data.

Data Extraction

Where possible, individual level data on blood pressure estimates were extracted from survey microdata and these were collapsed across individuals and collapsed across demographic groupings to produce mean estimates in the standard GBD 5-year age-sex groups. If microdata were unavailable, information from survey reports or from literature were extracted along with any available measure of uncertainty including standard error, uncertainty intervals, and sample size. Standard deviations were also extracted. Where mean systolic blood pressure was reported split out by groups other than age, sex, location, and year (eg, by hypertensive status), a weighted mean was calculated.

Incorporating United States prevalence data

Survey reports and literature often report information only about the prevalence, but not the level, of hypertension in the population studied. These sources were not used to model systolic blood pressure, with the exception of data from the Behavioral Risk Factors Surveillance System (BRFSS) because of the availability of a similarly structured exam survey that is representative of the same population (NHANES). BRFSS is a telephone survey conducted in the United States for all US counties. It collects self-reported diagnosis of hypertension. These self-reported values of prevalence of raised blood pressure were adjusted for self-report bias and tabulated by age group, sex, US state, and year. These prevalences were used to predict a mean systolic blood pressure for the same strata with a regression using data from the National Health and Nutrition Examination Survey, a nationally representative health examination survey of the US adult population. The regression was run separately by sex, and was specified as:

$$\mathrm{SBP}_{\mathrm{l,a,t,s}} = \beta_0 + \beta_1 \mathrm{prev}_{\mathrm{l,a,t,s}}$$

where $\mathrm{SBP}_{\mathrm{l,a,t,s}}$ is the location, age, time, and sex specific mean systolic blood pressure and $\mathrm{prev}_{\mathrm{l,a,t,s}}$ is the location, age, time, and sex specific prevalence of raised blood pressure. The coefficients for both models are reported in Table 1.

Table 1. Coefficients in the sex-specific US states blood pressure prediction models

Term	Male model	Female model
Intercept (β_0)	114.65	108.28
Prevalence (β_1)	51.86	68.87

Out of sample RMSE was used to quantify the predictive validity of the model. The regression was repeated 10 times for each sex, each time randomly holding out 20% of the data. The RMSEs from each holdout analysis were averaged to get the average out of sample RMSE. The results of this holdout analysis are reported in Table 2.

Table 2. Out of sample RMSEs of the sex-specific US states blood pressure prediction models

	Male model	Female model
Out of sample RMSE	2.37 mmHg	3.27 mmHg

Age and Sex Splitting

Prior to modelling, data provided in age groups wider than the GBD 5-year age groups were processed using the approach outlined in Ng et al.[2] Briefly, an age-sex pattern were identified using 115 sources of microdata with multiple age-sex groups, and these patterns were applied to estimate age-sex specific levels of mean systolic blood pressure from aggregated results reported in published literature or survey reports. In order to incorporate uncertainty into this process and borrow strength across age groups when constructing the age-sex pattern, we used a model with auto-regression on the change in mean SBP over age groups:

$$\mu_a = \mu_{a-1} + \omega_a$$
$$\omega_a \sim N(\omega_{a-1}, \tau)$$

Where μ_a is the mean predicted value for age group *a*, μ_{a-1} is the mean predicted value for the age group previous to age group *a*, ω_a is the difference in mean between age group *a* and age group *a-1*, ω_{a-1} is the difference between age group *a-1* and age group *a-2*, and τ is a user-input prior on how quickly the mean SBP changes for each unit increase in age. We used a τ of 1.5 mmHg for this model. Draws of the age-sex pattern were combined with draws of the input data needing to be split in order to calculate the new variance of age-sex split data points.

Modelling

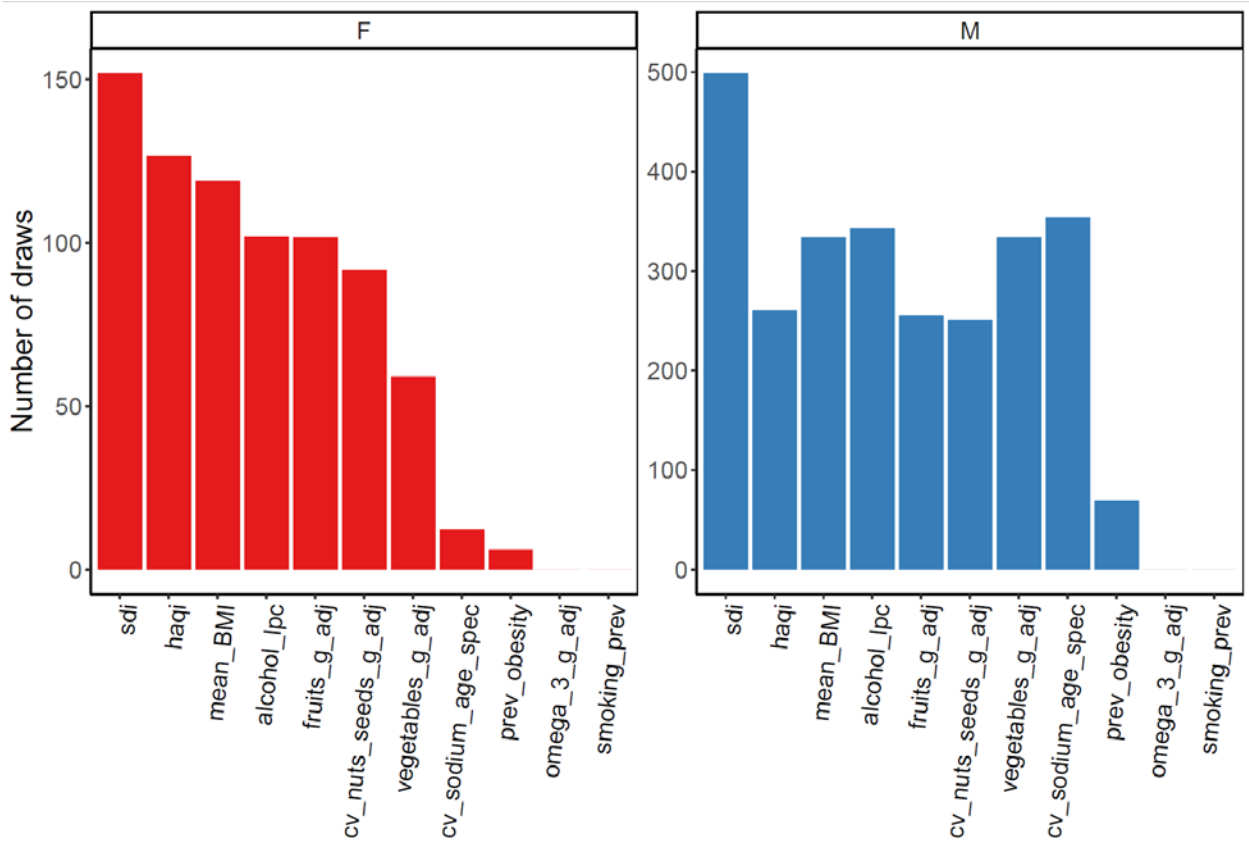
Exposure estimates were produced from 1980 to 2016 for each national and subnational location, sex, and for each 5-year age group starting from 25+. As in GBD 2016, we used a Spatio-Temporal Gaussian Process Regression (ST-GPR) framework to model the mean systolic blood pressure at the location-, year-, age-, sex- level.

Covariate selection

The first step of the ST-GPR framework requires the creation of a linear model for predicting SBP at the location-, year-, age-, sex- level. Covariates for this model were selected in two stages. First a list of variables with an expected causal relationship with SBP was created based on significant association found within high-quality prospective cohort studies reported in the published scientific literature. The second stage in covariate selection was to test the predictive validity of every possible combination of covariates in the linear model, given the covariates selected above. This was done separately for each sex. Predictive validity was measured with out of sample root-mean-squared error.

In GBD 2016, the linear model with the lowest root-mean squared error for each sex was then used in the ST-GPR model. In GBD 2017, we used an ensemble model of the 50 models with the lowest root-mean squared error for each sex. This allows us to utilise covariate information from many plausible linear mixed-effects models. The 50 models were each used to predict the mean SBP for every age, sex, location, and year, and the inverse-RMSE-weighted average of this set of 50 predictions was used as the linear prior. The relative weight in 'draws' contributed by each covariate is plotted by sex in Figure 2.

Figure 2. Results of the ensemble linear model covariate selection



The results of the ensemble linear model were used for the first stage in an ST-GPR model. Methodological updates to ST-GPR are reported above. The result of the ST-GPR model are estimates of the mean SBP for each age, sex, location, and year.

Estimate of Standard Deviation

Currently, the ST-GPR model only produces an estimate of mean exposure level without standard deviation. Therefore, the standard deviation of systolic blood pressure within a population was estimated for each national and subnational location, sex, and 5-year age group starting from age 25 using the standard deviation from person-level and some tabulated data sources. Person-level microdata accounted for 10375 of the total 12570 rows of data on standard deviation. The remaining 2195 rows came from tabulated data. Tabulated data was only used to model standard deviation if it was sex and 5-year age group specific and reported a population standard deviation of systolic blood pressure. The systolic blood pressure standard deviation function was estimated using a linear regression:

$$\log(\mathrm{SD}_{l,a,t,s}) = \beta_0 + \beta_1 \log(\mathrm{mean\_SBP}_{l,a,t,s}) + \beta_4 \mathrm{sex} + \sum_{k=2}^{16} \beta_k I_A$$

where $\mathrm{mean\_SBP}_{l,a,t,s}$ is the location, age, time, and sex specific mean SBP estimate from ST-GPR, and I_A is a dummy variable for a fixed effect on a given 5-year age group.

Adjustment for Usual Levels of Blood Pressure

To account for in-person variation in systolic blood pressure, a 'usual blood pressure' adjustment was done. The need for this adjustment has been described elsewhere.5 Briefly, measurements of a risk factor taken at a single time point may not accurately capture an individual's true long-term exposure to that risk. Blood pressure readings are highly variable over time due to measurement error as well as diurnal, seasonal, or biological variation. These sources of variation result in an over-estimation of the variation in cross-sectional studies of the distribution of SBP.

To adjust for this overestimation, we applied a correction factor to each location-, age-, time-, and sex-specific standard deviation. These correction factors were age-specific, and represented the proportion of the variation in blood pressure within a population that would be observed if there were no within-person variation across time. Four longitudinal surveys were used to estimate these factors: the China Health and Retirement Longitudinal Survey (CHRLS), the Indonesia Family Life Survey (IFLS), the National Health and Nutrition Examination Survey I Epidemiological Follow-up Study (NHANES I/EFS), and the South Africa National Income Dynamics Survey (NIDS). The sample size and number of blood pressure measurements at each measurement period for each survey is reported in Table 5.

Table 3. Characteristics of longitudinal surveys used for the usual blood pressure adjustment

Source	Measurement periods	Number of measurements	Sample size
CHRLS	2008	3	1967
	2012	3	1419
IFLS	1997	1	19418
	2000	1	16626
	2007	3	14136
NIDS	1997	2	14084
	2000	2	9612
	2007	2	9098
NHANES I/EFS	1971-1976	2	20716
	1982-1984	3	9932

For each survey, the following regression was created for each age group:

$$\mathrm{SBP}_{i,a} = \beta_0 + \beta_1 \mathrm{sex} + \beta_3 \mathrm{age} + + \upsilon_i$$

where $\mathrm{SBP}_{i,a}$ is the systolic blood pressure of an individual i at age a, sex is a dummy variable for the sex of an individual, age is a continuous variable for the age of an individual, and υ_i is a random intercept for each individual. Then, a blood pressure value $\widehat{\mathrm{SBP}}_{i,b}$ was predicted for each individual i for his/her age at baseline b. The correction factor cf for each age group within each survey was calculated as variation in these predicted blood pressures was divided by the variation in the observed blood pressures at baseline, $\mathrm{SBP}_{i,b}$:

$$\mathrm{cf} = \sqrt{\frac{\mathrm{var}\left(\widehat{\mathrm{SBP}}_b\right)}{\mathrm{var}\left(\mathrm{SBP}_b\right)}}$$

The average of the correction factors was taken over the three surveys to get one set of age-specific correction factors, which were then multiplied by the square of the modelled standard deviations to estimate standard deviation of the 'usual blood pressure' of each age, sex, location, and year. Because of low sample sizes, the correction factors for the 75-79 age group was used for all terminal age groups. The final correction factors for each age group are reported in Table 6. Figure 1 shows the correction factors by survey and age group ID.

Table 4. Age-specific usual blood pressure correction factors

Age group	Correction factor
25-29	.665
30-34	.713
35-39	.737
40-44	.733
45-49	.798
50-54	.771
55-59	.764
60-64	.753
65-69	.719
70-74	.689
75+	.678

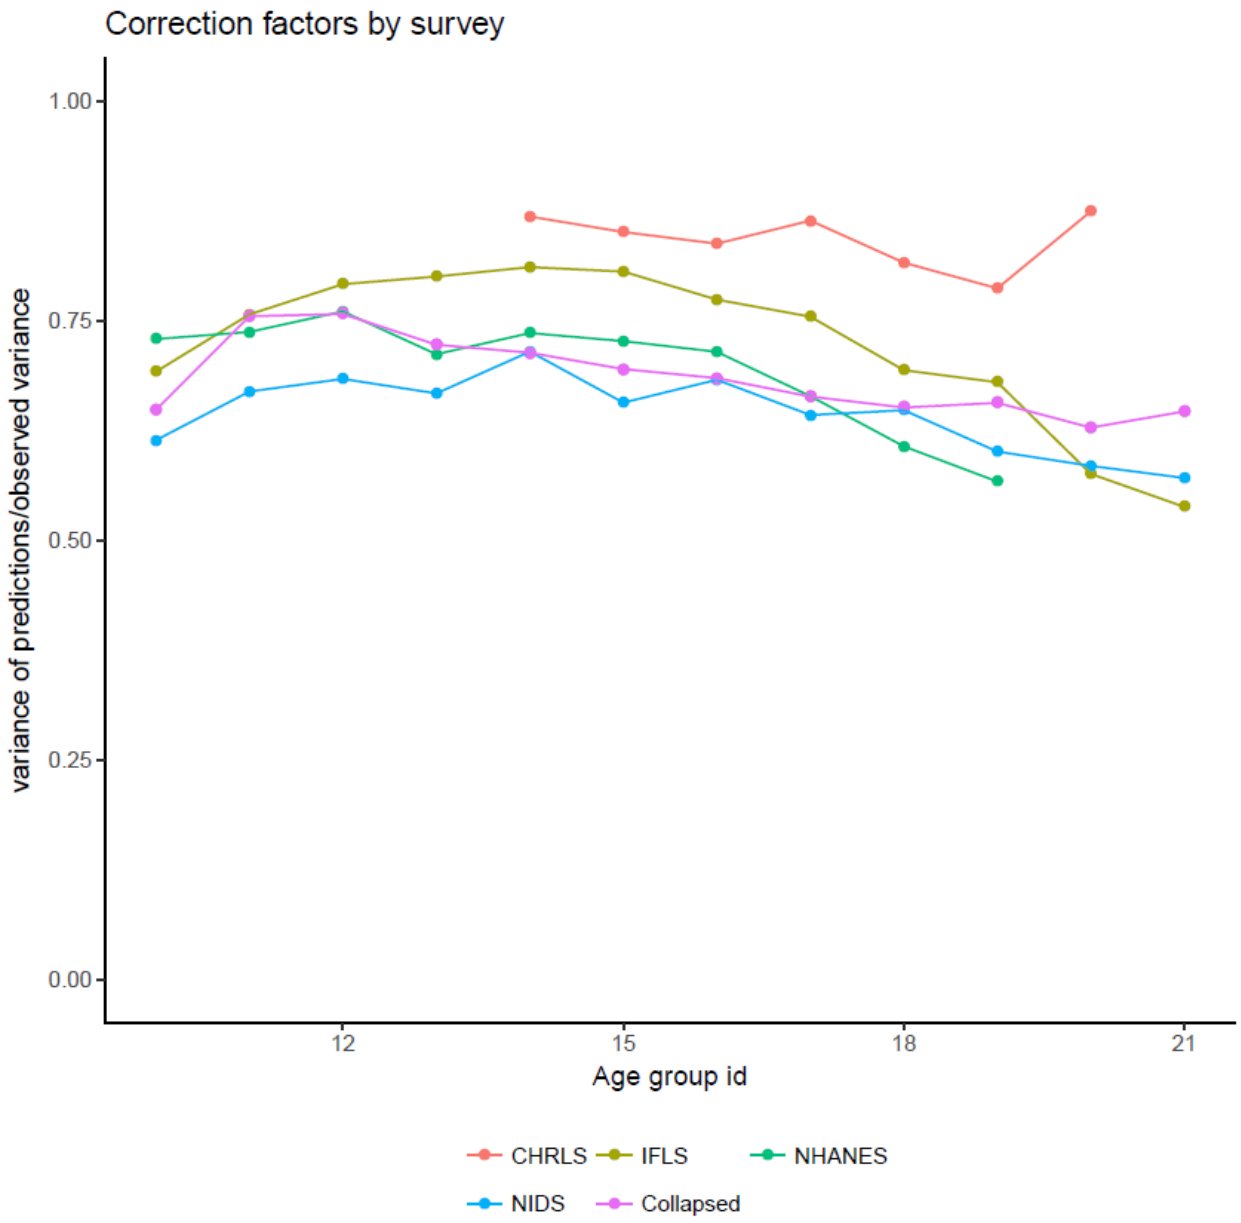


Figure 1: Correction factor by survey and age group id. The correction factor is equal to the variance of the predictions divided by the variance of the raw dataset. In pink is the average correction factor for each age group, summarised in Table 6.

A visualisation of how the uncorrected blood pressure measurements overestimate the 'usual' blood pressure variation is shown in Figure 1. This image shows the density of the distribution of the observed blood pressure values $SBP_{i,b}$ in participants in the Indonesian Family Life Study survey in red, and the density of the predicted blood pressure values $\widehat{SBP}_{i,b}$ in blue. The ratio of the variance of the blue distribution to the variance of the red distribution is an example of the scalar adjustment factor being applied to the modelled standard deviations.

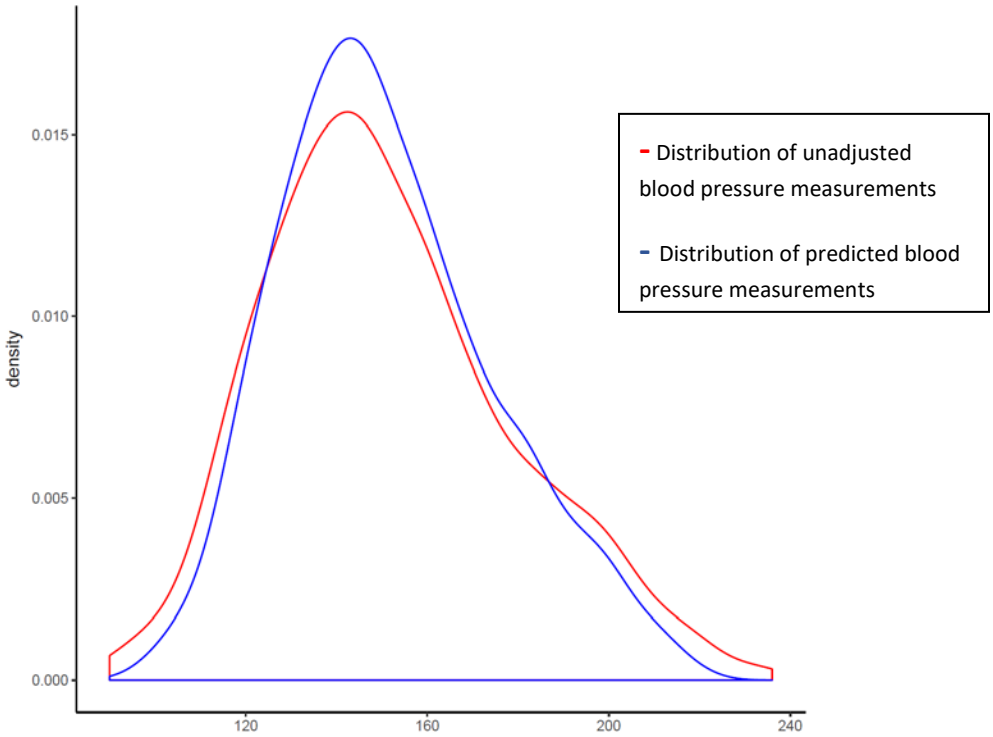

Figure 2: Raw and predicted distributions of blood pressure in the Indonesia Family Life Survey

Estimating the exposure distribution shape

The shape of the distribution of systolic blood pressure was estimated using all available person-level microdata sources, which was a subset of the input data into the modelling process. The distribution shape modelling framework for GBD 2017 is detailed in the appendix. Briefly, an ensemble distribution created from a weighted average of distribution families was fit for each individual microdata source, separately by sex. The weights for the distribution families for each individual source were then averaged and weighted to create a global ensemble distribution for each sex.

Theoretical minimum-risk exposure level

No changes were made to TMREL used in the GBD2015 study. We estimated that the TMREL of SBP ranges from 110 to 115 mm Hg based on pooled prospective cohort studies that show risk of mortality increases for SBP above that level.[3,4] Our selection of a TMREL of 110-115 mmHg is consistent with the GBD study approach of estimating all attributable health loss that could be prevented even if current interventions do not exist that can achieve such a change in exposure level, for example a tobacco smoking prevalence of zero percent. To include the uncertainty in the TMREL, we took a random draw from the uniform distribution of the interval between 110 mm and 115 mm Hg each time the population attributable burden was calculated.

Relative risks

No change was made to RR for blood pressure outcomes used in the GBD2016 study. RRs for chronic kidney disease are from the Renal Risk Collaboration meta-analysis of 2.7 million individuals in 106 cohorts. For other outcomes, we used data from two pooled epidemiological studies: the Asia Pacific Cohort Studies Collaboration (APCSC) and the Prospective Studies Collaboration (PSC).[4,5] Additional estimates of RR for cardiovascular outcomes were used from the CALIBER study, a health-record linkage cohort study from the UK.[6]

For cardiovascular disease, epidemiological studies have shown that the RR associated with SBP declines with age, with the log (RR) having an approximately linear relationship with age and reaching a value of 1 between the ages of 100 and 120. RRs were reported per 10 mm Hg increase in SBP above the TMREL value (115 mm Hg), calculated as in the equation below:

$$RR(x) = RR_0^{\frac{(x-TMREL)}{10\ mmHg}}$$

Where $RR(x)$ is the RR at exposure level x and RR_0 is the increase in RR for each 10 mmHg above the TMREL. We used Dismod-MR 2.1 to pool effect sizes from included studies and generate a dose-response curve for each of the outcomes associated with high SBP. The tool enabled us to incorporate random effects across studies and include data with different age ranges. RRs were used universally for all countries and the meta-regression only helped to pool the three major sources and produce RRs with uncertainty and covariance across ages taking into account the uncertainty of the data points.

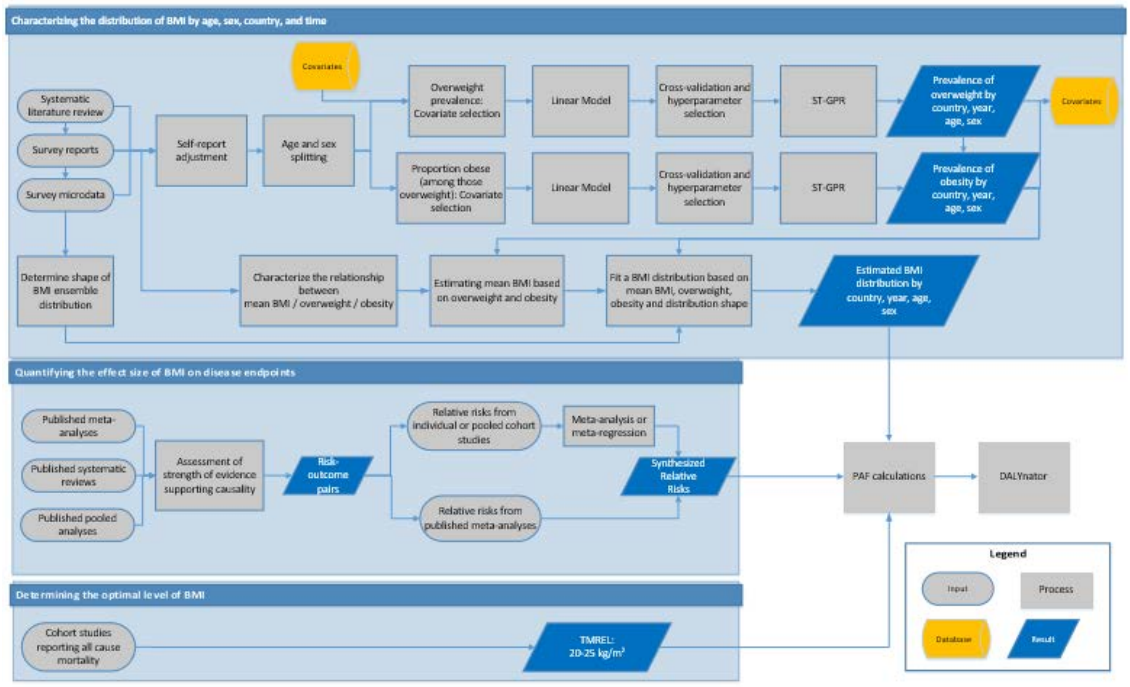
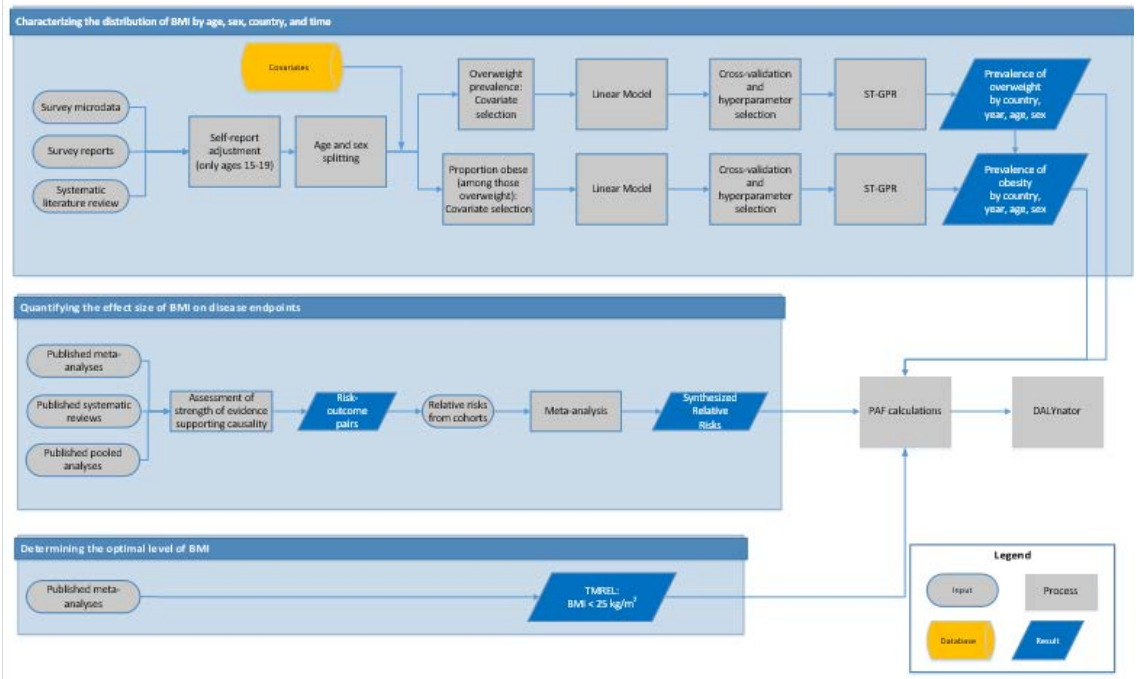
High Body-Mass Index Capstone Appendix

Flowchart

Adult (Ages 20+) High Body-Mass Index: Data and Model Flow Chart



Childhood (Ages 2-19) High Body-Mass Index: Data and Model Flow Chart



Case definitions

High body-mass index (BMI) for adults (ages 20+) is defined as BMI greater than 20 to 25 kg/m^2. High BMI for children (ages 1-19) is defined as being overweight or obese based on International Obesity Task Force standards.

Input data and methodological summary

Data sources

We systematically searched Medline to identify studies providing nationally or subnationally representative estimates of overweight prevalence, obesity prevalence or mean body-mass index (BMI). We limited the search to literature published between January 1, 2016 and December 31, 2016 to update the systematic literature search previously performed as part of GBD 2015.

The search for adults was conducted on 4 January 2017 using the following terms:

((("Body Mass Index"[Mesh] OR "Overweight"[Mesh] OR "Obesity"[Mesh]) AND ("Geographic Locations"[Mesh] NOT "United States"[Mesh]) AND ("humans"[Mesh] AND "adult"[MeSH]) AND ("Data Collection"[Mesh] OR "Health Services Research"[Mesh] OR "Population Surveillance"[Mesh] OR "Vital statistics"[Mesh] OR "Population"[Mesh] OR "Epidemiology"[Mesh] OR "surve*"[TiAb]) NOT (Comment[ptyp] OR Case Reports[ptyp] OR "hospital"[TiAb])) AND ("2016/01/01"[Date - Publication] : "2016/12/31"[Date - Publication]))

The search for children was conducted on 4 August 2016 using the following terms:
((("Body Mass Index"[Mesh] OR "Overweight"[Mesh] OR "Obesity"[Mesh]) AND ("Geographic Locations"[Mesh] NOT "United States"[Mesh]) AND ("humans"[Mesh] AND "child"[MeSH]) AND ("Data Collection"[Mesh] OR "Health Services Research"[Mesh] OR "Population Surveillance"[Mesh] OR "Vital statistics"[Mesh] OR "Population"[Mesh] OR "Epidemiology"[Mesh] OR "surve*"[TiAb]) NOT (Comment[ptyp] OR Case Reports[ptyp] OR "hospital"[TiAb])) AND ("2016/01/01"[Date - Publication] : "2016/12/31"[Date - Publication]))

Our search for adult estimates identified 456 abstracts, of which 25 met inclusion criteria and were extracted. The search for childhood estimates identified 137 articles, of which 4 were extracted. Including sources from the previous GBD systematic literature searches, a total of 11,220 articles were identified, of which 845 were included. Additionally, we searched the Global Health Data Exchange (GHDx) database for individual-level data from major multinational survey series or country-specific surveys and identified 5,385 location-year sources meeting the inclusion criteria.

Eligibility criteria

We included representative studies providing data on mean BMI or prevalence of overweight or obesity among adults or children. For adults, studies were included if they defined overweight as BMI≥25 kg/m^2 and obesity as BMI≥30 kg/m^2, or if estimates using those cutoffs could be back-calculated from reported categories. For children (children ages 2-18), studies were included if they used International Obesity Task Force (IOTF) standards to define overweight and obesity thresholds. We only included studies reporting data collected between January 1, 1980 and December 31, 2016. Studies were excluded if they used non-random samples (e.g. case-control studies or convenience samples), conducted among specific subpopulations (e.g. pregnant women, racial or ethnic minorities, immigrants, or individuals with specific diseases), used alternative methods to assess adiposity (e.g. waist-circumference, skin-fold thickness, or hydrodensitometry), had sample sizes of less than 20 per age-sex group, or provided inadequate

information on any of the inclusion criteria. We also excluded review articles and non-English language articles.

Data collection process

Where individual-level survey data were available, we computed mean BMI using weight and height. We then used BMI to determine the prevalence of overweight and obesity. For individuals aged over 18 years, we considered them to be overweight if their BMI was greater than or equal to 25 kg/m^2, and obese if their BMI was greater than or equal to 30 kg/m^2. For individuals aged 2 to 18 years, we used monthly IOTF cutoffs[2] to determine overweight and obese status when age in months was available. When only age in years was available, we used the cutoff for the midpoint of that year. Obese individuals were also considered to be overweight. We excluded studies using the World Health Organization (WHO) standards or country-specific cutoffs to define childhood overweight and obesity. At the individual-level, we considered BMI<10 kg/m^2 and BMI>70 kg/m^2 to be biologically implausible and excluded those observations.

The rationale for choosing to use the IOTF cutoffs over the WHO standards has been described elsewhere.[1] Briefly, the IOTF cutoffs provide consistent child-specific standards for ages 2-18 derived surveys covering multiple countries. On the other hand, the WHO growth standards apply to children under age 5 and the WHO growth reference applies to children ages 5 to 19. The WHO growth reference for children ages 5 to 19 was derived from United States data which is less representative than the multinational data used by IOTF. Additionally, the switch between references at age 5 can produce artificial discontinuities. Given that we estimate global childhood overweight and obesity for ages 2-19 (with ages 19 using standard adult cutoffs), the IOTF cutoffs were preferable. Additionally, we found that IOTF cutoffs were more commonly used in scientific literature covering childhood obesity.

From report and literature data, we extracted data on mean BMI, prevalence of overweight, and prevalence of obesity, measures of uncertainty for each, and sample size, by the most granular age and sex groups available. Additionally, we extracted the same study-level covariates as were extracted from microdata (measurement, urbanicity, and representativeness), as well as location and year.

In addition to the primary indicators described above, we extracted relevant survey-design variables, including primary sampling unit, strata, and survey weights, which were used to tabulate individual-level microdata and produce accurate measures of uncertainty. We extracted three study-level covariates: 1) whether height and weight data were measured or self-reported; 2) whether the study was predominantly conducted in an urban area, rural area or both; and 3) the level of representativeness of the study (national or subnational).

Finally, we extracted relevant demographic indicators, including location, year, age and sex. We estimated the standard error of the mean from individual-level data, where available, and used the reported standard error of the mean for published data. When multiple data sources were available for the same country, we included all of them in our analysis. If data from the same data source were available in multiple formats such individual-level data and tabulated data, we used individual-level data.

Self-report bias adjustment

We included both measured and self-reported data. We tested for bias in self-report data compared to measured data, which is considered to be the gold-standard. There was no clear direction of bias for children ages 2 to 14, so for these age groups we only included measured data. For individuals ages 15

and above, we adjusted self-reported data for overweight prevalence, obesity prevalence and mean BMI using the following nested hierarchical mixed-effects regression models, fit using restricted maximum likelihood separately by sex:

$$\text{logit}(\text{overweight})_{c,a,t} = \beta_0 + \beta_1 m + \sum_{k=2}^{19} \beta_k I_{A[a]} + \sum_{l=20}^{55} \beta_l I_{A[a]} I_{M[m]} + \alpha_s + \alpha_s m + \alpha_r + \alpha_r m + \alpha_c + \alpha_c m + \alpha_t + \alpha_t m + \epsilon_{c,a,t}$$

$$\text{logit}(\text{obesity})_{c,a,t} = \beta_0 + \beta_1 m + \sum_{k=2}^{19} \beta_k I_{A[a]} + \sum_{l=20}^{55} \beta_l I_{A[a]} I_{M[m]} + \alpha_s + \alpha_s m + \alpha_r + \alpha_r m + \alpha_c + \alpha_c m + \alpha_t + \alpha_t m + \epsilon_{c,a,t}$$

$$\log(\text{BMI})_{c,a,t} = \beta_0 + \beta_1 m + \sum_{k=2}^{19} \beta_k I_{A[a]} + \sum_{l=20}^{55} \beta_l I_{A[a]} I_{M[m]} + \alpha_s + \alpha_s m + \alpha_r + \alpha_r m + \alpha_c + \alpha_c m + \alpha_t + \alpha_t m + \epsilon_{c,a,t}$$

Where m is a fixed effect on measurement (binary, either measured (1) or self-report (0)), $I_{A[a]}$ is an indicator variable for specific age group A, $I_{A[a]} I_{M[m]}$ is an interaction term between age and measurement, α_s, α_r, and α_c are random effects at the super region, region, and country, respectively, and α_t is a random effect by time-period (1980-1989, 1990-1999, 2000-2009, 2010-2017). Random effects at the country level and time-period level were used to fit the models, but were taken as noise and were not used in adjustment of self-reported data. We propagated the uncertainty in the self-report adjustment model by adding the variance of each of the regression coefficients used in adjustment to the data variance in delta-transformed space. After adjustment, regressions confirmed that self-reported data was no longer significantly different from measured data.

Age and sex splitting

Any report or literature data provided in age groups wider than the standard 5-year age groups or as both sexes combined were split using the approach used by Ng et al.[2] Briefly, age-sex patterns were identified using sources with data on multiple age-sex groups and these patterns were applied to split aggregated report and literature data. Uncertainty in the age-sex split was propagated by multiplying the standard error of the data by the square root of the number of splits performed. We did not propagate the uncertainty in the age pattern and sex pattern used to split the data as they seemed to have small effect.

Prevalence estimation for overweight and obesity

After adjusting for self-report bias and splitting aggregated data into 5-year age-sex groups, we used spatiotemporal Gaussian process regression (ST-GPR) to estimate the prevalence of overweight and obesity. This modelling approach has been described in detail elsewhere.

The linear model, which when added to the smoothed residuals forms the mean prior for GPR is as follows:

$$\text{logit}(\text{overweight})_{c,a,t} = \beta_0 + \beta_1 \text{energy}_{c,t} + \beta_2 \text{SDI}_{c,t} + \beta_3 \text{vehicles}_{c,t} + \beta_4 \text{agriculture}_{c,t} + \sum_{k=5}^{21} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_c$$

$$\text{logit}(\text{obesity/overweight})_{c,a,t} = \beta_0 + \beta_1 \text{energy}_{c,t} + \beta_2 \text{SDI}_{c,t} + \beta_3 \text{vehicles}_{c,t} + \sum_{k=4}^{21} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_c$$

where $energy$ is ten-year lag-distributed energy consumption per capita, SDI is a composite index of development including lag-distributed income per capita, education, and fertility, $vehicles$ is is the number of two or four-wheel vehicles per capita, and $agriculture$ is the proportion of the population working in agriculture. $I_{A[a]}$ is a dummy variable indicating specific age group A that the prevalence point

captures, and α_s, α_r, and α_c are super region, region, and country random intercepts, respectively. Random effects were used in model fitting but were not used in prediction.

We tested all combinations of the following covariates to see which performed best in terms of in-sample AIC for the overweight linear model and the obesity as a proportion of overweight linear model: ten-year lag distributed energy per capita, proportion of the population living in urban areas, SDI, lag-distributed income per capita, educational attainment (years) per capita, proportion of the population working in agriculture, grams of sugar adjusted for energy per capita, grams of sugar not adjusted for energy per capita, and the number of two or four-wheeled vehicles per capita. We selected these candidate covariates based on theory as well as reviewing covariates used in other publications. The final linear model was selected based on: 1) if the direction of covariates matched what is expected from theory, 2) all the included covariates were significant, and 3) minimising in-sample AIC. The covariate selection process was performed using the dredge package in R.

The new version of ST-GPR for GBD 2017 incorporates information about data density into the process for smoothing over space and time. Estimates in areas/years with few observations have more weight on regional observations. To specify the distribution of time weights and space weights, we used values of lambda=0.2 and zeta=0.05, respectively. We used a value of omega=1.0 for the distribution of age weights. We set the GPR scale parameter to 20, and used the default global cutoff setting for amplitude.

Estimating mean BMI

To estimate the mean BMI for adults in each country, age, sex, and time period 1980-2017, we first used the following nested hierarchical mixed-effects model, fit using restricted maximum likelihood on data from sources containing estimates of all three indicators (prevalence of overweight, prevalence of obesity, and mean BMI), in order to characterise the relationship between overweight, obesity, and mean BMI:

$$\log(\mathrm{BMI}_{c,a,s,t}) = \beta_0 + \beta_1 \mathrm{ow}_{c,a,s,t} + \beta_2 \mathrm{ob}_{c,a,s,t} + \beta_3 \mathrm{sex} + \sum_{k=4}^{20} \beta_k I_{A[a]} + \alpha_s(1 + \mathrm{ow}_{c,a,s,t} + \mathrm{ob}_{c,a,s,t}) + \alpha_r(1 + \mathrm{ow}_{c,a,s,t} + \mathrm{ob}_{c,a,s,t}) + \alpha_c(1 + \mathrm{ow}_{c,a,s,t} + \mathrm{ob}_{c,a,s,t}) + \epsilon_{c,a,s,t}$$

where $\mathrm{ow}_{c,a,s,t}$ is the prevalence of overweight in country c, age a, sex s, and year t, $\mathrm{ob}_{c,a,s,t}$ is the prevalence of obesity in country c, age a, sex s, and year t, sex is a fixed effect on sex, $I_{A[a]}$ is an indicator variable for age, and α_s, α_r, and α_c are random effects at the super region, region, and country, respectively. The model was run in Stata 13.

We applied 1,000 draws of the regression coefficients to the 1,000 draws of overweight prevalence and obesity prevalence produced through ST-GPR to estimate 1,000 draws of mean BMI for each country, year, age, and sex. This approach ensured that overweight prevalence, obesity prevalence, and mean BMI were correlated at the draw level and uncertainty was propagated.

Estimating BMI distribution

We used the ensemble distribution approach described in the manuscript. We fit ensemble weights by source and sex, with source- and sex-specific weights averaged across all sources included to produce the final global weights. The ensemble weights were fit on measured microdata. The final ensemble weights were: exponential = 0.002, gamma = 0.028, inverse gamma = 0.085, log-logistic = 0.187, Gumbel = 0.220,

Weibull = 0.011, log-normal = 0.058, normal = 0.012, beta = 0.136, mirror gamma = 0.008, and mirror Gumbel = 0.113.

One thousand draws of BMI distributions for each location, year, age group, and sex estimated were produced by fitting an ensemble distribution using 1,000 draws of estimated mean BMI, 1,000 draws of estimated standard deviation, and the ensemble weights. Estimated standard deviation was produced by optimising a standard deviation to fit estimated overweight prevalence draws and estimated obesity prevalence draws.

Assessment of risk-outcome pairs

Risk-outcome pairs were defined based on strength of available evidence supporting a causal effect. We performed a systematic review of published meta-analyses, pooled analyses, and systematic reviews available through PubMed using the following search string: ("Body Mass Index"[Mesh] OR "Overweight"[Mesh] OR "Obesity"[Mesh]) AND (Meta-Analysis[ptyp] OR "systematic review"[tiab] OR "pooled analysis"[tiab]). Inclusion criteria are 1) the health outcome is included in GBD, 2) at least one prospective cohort is included, and 3) that the summary effect size is statistically significant. For outcomes meeting inclusion criteria we completed causal criteria tables to evaluate the strength of evidence supporting a causal relationship (see Appendix Table 4). Gallbladder disease, cataract, multiple myeloma, gout, non-Hodgkin lymphoma, asthma, Alzheimer disease, and atrial fibrillation were added as new outcomes in GBD 2016, resulting in a total of 38 outcomes.

Theoretical minimum risk exposure level

For adults (ages 20+), the theoretical minimum risk exposure level (TMREL) of BMI (20-25 kg/m^2) was determined based on the BMI level that was associated with the lowest risk of all-cause mortality in prospective cohort studies.[3]

For children (ages 2-19), the TMREL is “normal weight,” that is, not overweight or obese, based on IOTF cutoffs.

Relative risk

The relative risk per 5-unit change in BMI for each disease endpoint was obtained from meta-analyses, and where available, pooled analyses of prospective observational studies. In cases where a relative risk per 5-unit change in BMI was not available we computed our own dose-response meta-analysis using two-step generalised least squares for time trends estimation methods.

For childhood outcomes (ages 2-19), we computed categorical relative risks for overweight and obesity using a random effects meta-analysis.

Relative risks for all 38 outcomes, by age and sex, are reported in Table 6a.

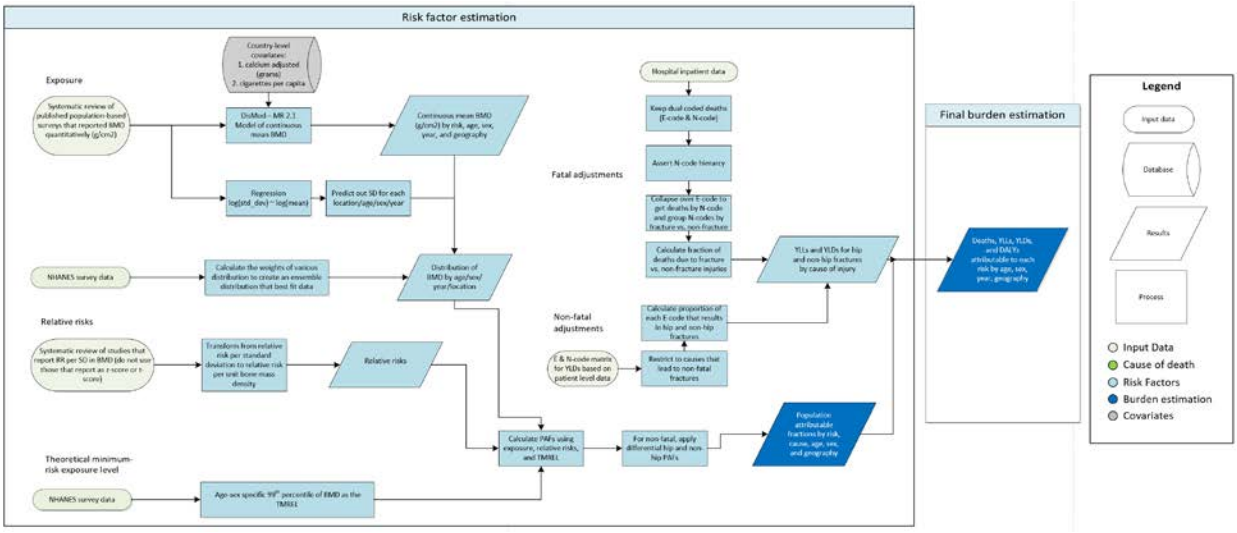
Bone Mineral Density Capstone Appendix

Flowchart



Input data & methodological summary

Exposure

Case definition

Bone mineral density (BMD) is a continuous variable measured by dual-x-ray-absorptiometry (DXA) at the femoral neck (FN) and is presented in g/cm^2 after standardizing for the brand of densitometer (sBMD). Low BMD is measured in terms of the difference between BMD of a population and the 99th percentile of a reference population at the same age and sex (theoretical minimum of risk exposure level, TMREL). The burden attributed to low bone mineral density is estimated for adults 20 years and older.

Input data

A systematic review (search string at the end of document) was conducted in GBD 2015 but it was not scheduled for systematic review in GBD 2016 or 2017. Inclusion criteria that informed the search are:

- Representative, population-based surveys
- Reporting of quantitative BMD
  - measured by DXA
  - performed at the FN region
  - measured in g/cm^2

Mean BMD was occasionally reported in stratified groups, e.g. by fracture status but not for total sample. In these cases, the stratified means were aggregated to obtain a total mean BMD at population level for an age or sex category.

The data availability by GBD super-region is shown in table below.

Super region	The number of data points
Southeast Asia, East Asia, and Oceania	314
Central Europe, Eastern Europe, and Central Asia	36
High-income	682
Latin America and Caribbean	97
North Africa and Middle East	110
South Asia	39
Sub-Saharan Africa	3

Modelling strategy

We modelled mean BMD in DisMod-MR 2.1 as a single 'continuous' parameter model by age and sex, and all GBD locations for years 1990 to 2017. The model had age mesh points at 0 10 20 25 30 40 50 60 70 80 90 & 100, a time window of 10 years for fitting data, and a minimum coefficient of variation of 0.1 for global, 0.06 super region and 0.08 for the region level.

The country covariates of alcohol consumption (litres per capita), tobacco consumption (cigarettes per capita), mean BMI, and adjusted calcium intake (g) were included in modelling. The country covariates total physical activity and milk consumption did not have a significant effect on BMD so we excluded them from our final model.

The uncertainty of BMD was modelled using various distributions. We tested goodness-of-fit in NHANES III data, the only survey for which we had unit record data available. We applied a weighting ensemble on those distributions. The weights were calculated in an optimisation model with an objective function that minimised Kolmogorov-Smirnov statistics. The weights of the distributions in the ensemble were calculated separately for males and females. Distribution weights are shown below.

Figure 1: Distribution of weights used for Females in GBD 2017

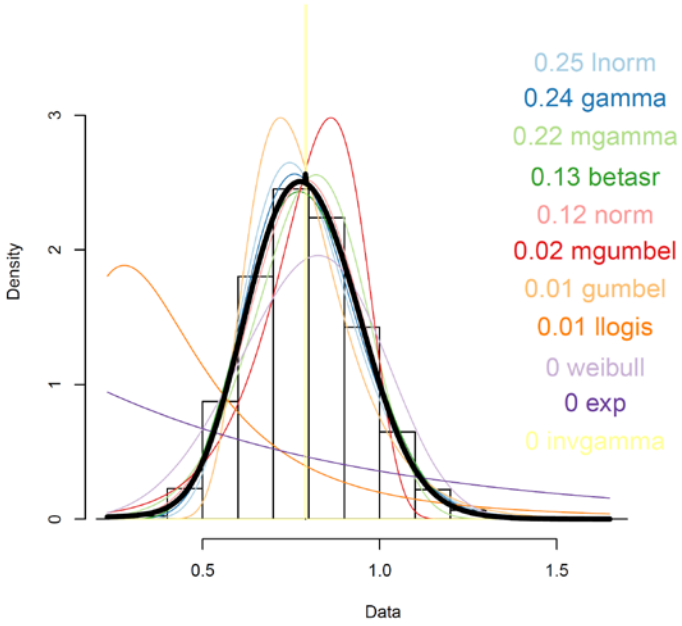


Figure 2: Distribution of weights used for Males in GBD 2017

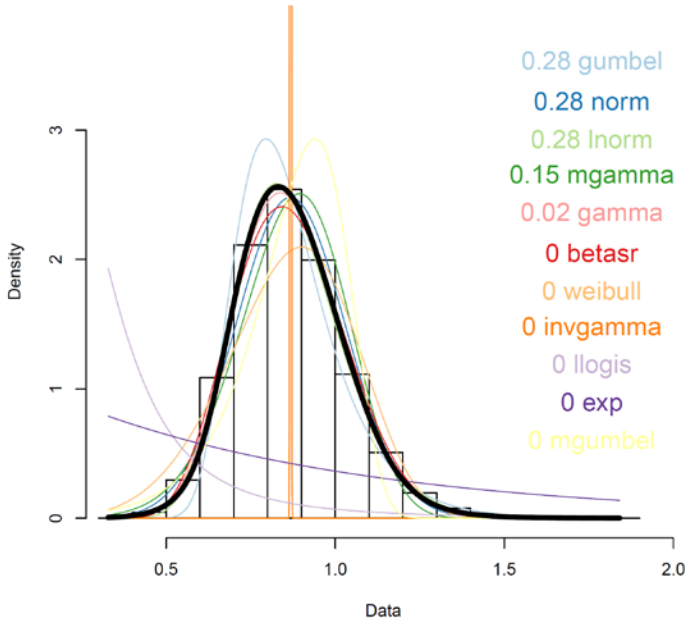


We consider the risk of fatal and non-fatal outcomes for hip non-hip fractures, separately, as relative risk data provide different estimates. Thus, there were various steps after DisMod-MR 2.1 exposure modelling to arrive at attributable fractions that can be applied to fatal and non-fatal fracture outcomes. These osteoporotic non-hip fractures include fractures of vertebrae, clavicle, scapula, humerus, skull, sternum, rib, face bone, radius or ulna, femur, patella, tibia, fibula, ankle, pelvis and vertebra.

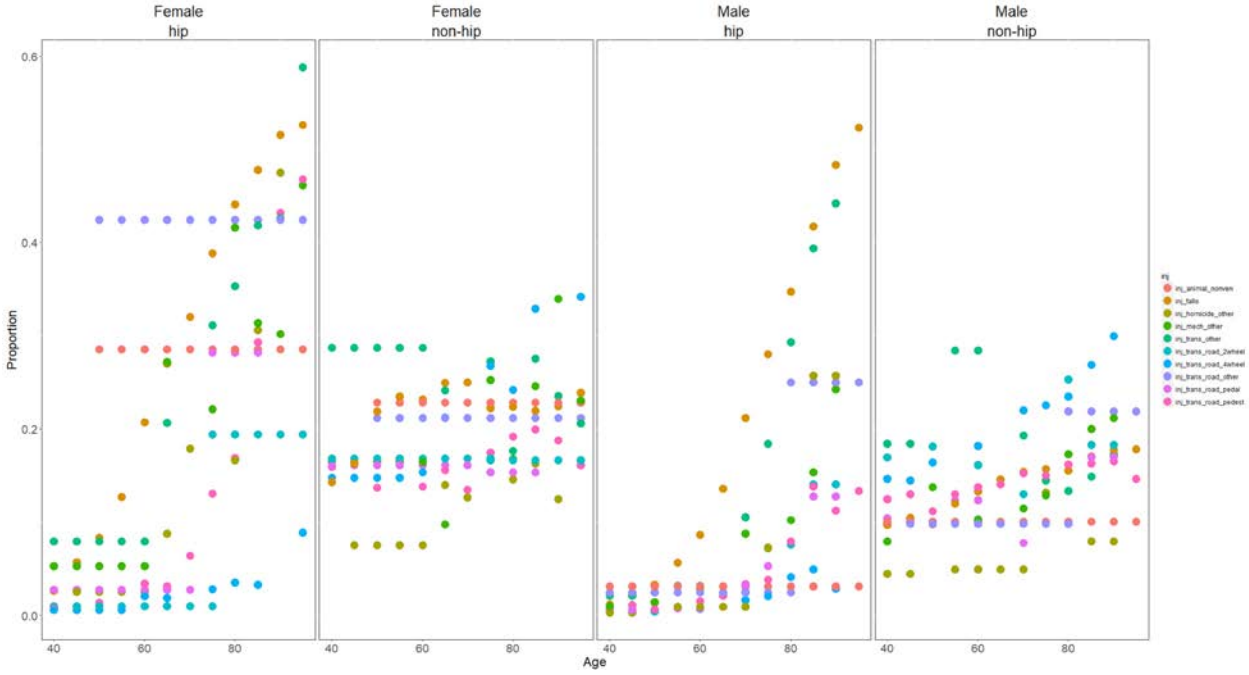
First, we calculated the proportion of injury deaths that are due to fractures. This proportion of death caused by fracture is the envelope that we use to attribute death to BMD. In order to do this, we assumed that hip fracture and some non-hip fractures (any fractures apart from fingers and toes) are potentially fatal fractures. As cause of death data from vital registration and verbal autopsy attributes injury deaths to causes of death (e.g. fall or road injury) and not nature of injury (such as fractures), we used available hospital data to estimate the proportion of injury deaths during admission that could be ascribed to fractures. We restricted our analysis to cases that were dual-coded with both the cause of injury ("E-code") and nature of injury ("N-code"). As injury cases may have multiple forms of trauma, we applied a severity hierarchy to the fatal hospital data to determine the proportion of the deaths that could be attributed to the chosen fracture types but were not accompanied by more severe fatal trauma such as head trauma, spinal cord lesion, and intra-abdominal or thoracic organ damage. We collapsed all deaths over E-code to determine the ratio of deaths attributable to fracture versus non-fracture injuries. We applied this ratio to the YLL.

We restricted non-fatal estimates of low BMD to a list of causes that were deemed to cause osteoporotic fractures. Below is the list of injuries for which a PAF was calculated:

- Transport injuries
- Road injuries
- Pedestrian road injuries
- Cyclist road injuries
- Motorcyclist road injuries
- Motor vehicle road injuries
- Other road injuries
- Other transport injuries
- Unintentional injuries
- Falls
- Exposure to mechanical forces
- Other exposure to mechanical forces
- Non-venomous animal contact
- Interpersonal violence
- Assault by other means

We made use of the E to N-code matrix generated from dual-coded (E-code/N-code) patient level data in our injury analyses to determine the proportion of each E-code that results in a certain N-code. The hip and non-hip fracture population attributable fractions were applied to the appropriate combinations of external cause and fracture estimates of YLD and then summed together to produce a single estimate.

Figure 3: Plot of hospital fractions used by hip and non-hip

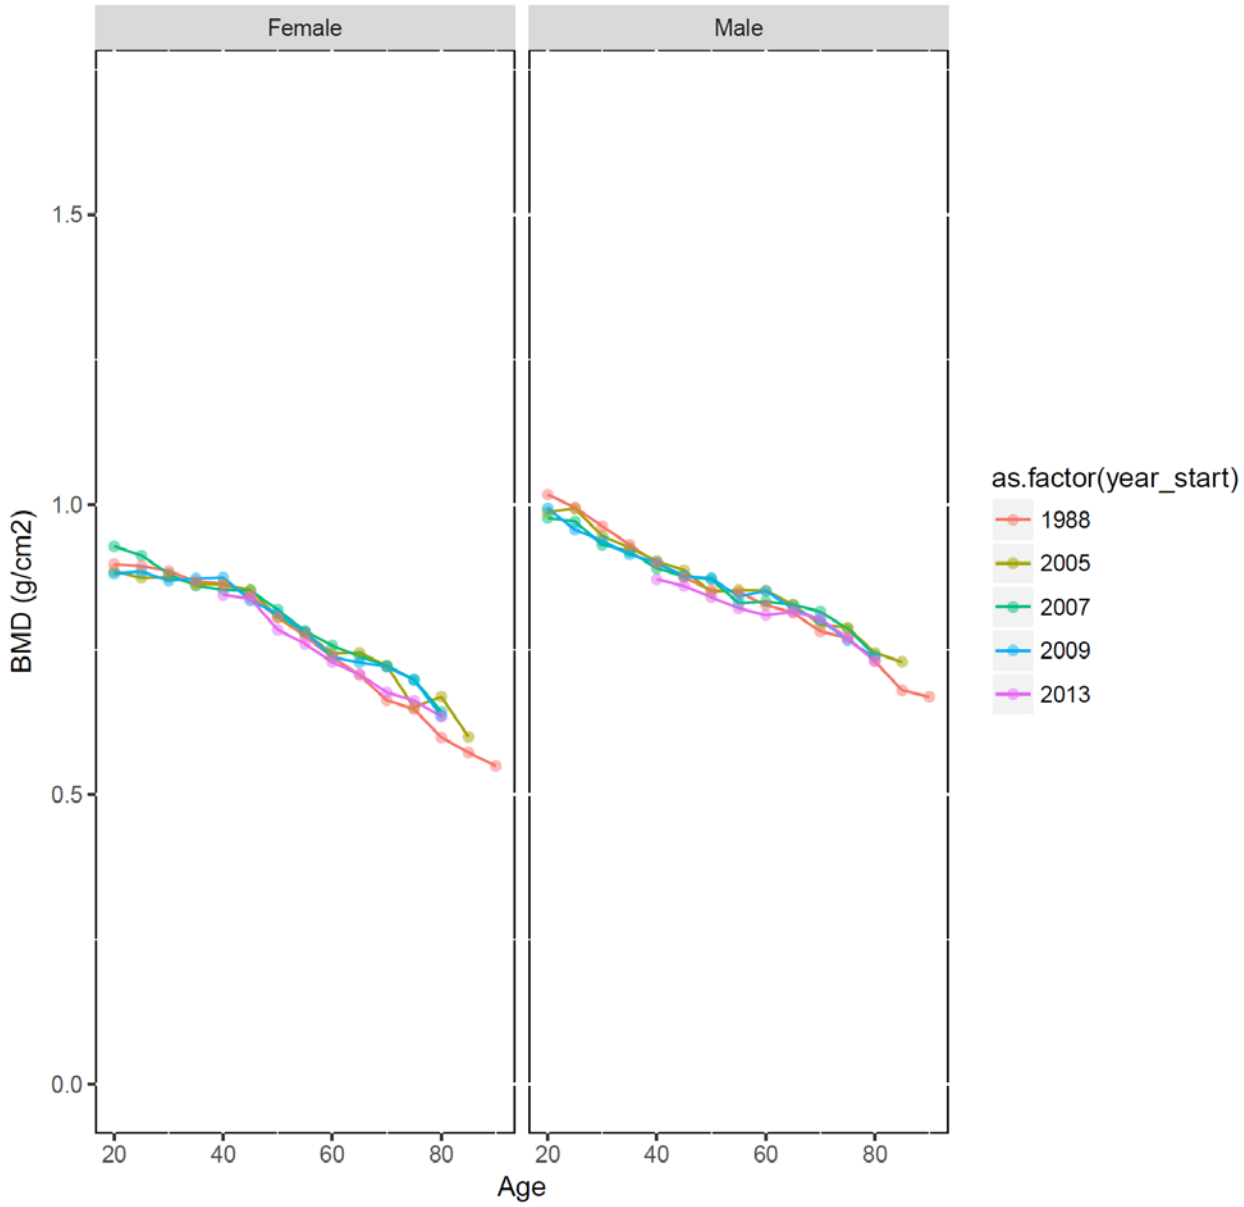


Theoretical minimum-risk exposure level

The theoretical minimum of risk exposure level or TMREL was chosen as the age-sex specific 99th percentile of BMD from 5 cycles of NHANES study as the reference population. Below is a descriptive table of the 5 NHANES cycles used.

NHANES cycle	Age range (years)	Number of people tested	BMD range (g/cm2)
1988	20 – 90	14,646	0.23 – 1.84
2005	20 – 85	3,494	0.40 – 1.50
2007	20 – 80	4,726	0.34 – 1.46
2009	20 – 80	5,052	0.33 – 1.63
2013	40 – 80	3,127	0.39 – 1.36

Figure 4: Plot of 99th percentile of BMD at femoral neck in each cycle of NHANES



Relative risks

Relative risks must be reported per standard deviation or per unit bone mass density in order for us to use the data. Many studies report relative risk based on a z-score or the relative risks in the osteoporotic group versus the non-osteoporotic group; neither of these relative risks are usable.

For GBD 2017, we did not update the systematic review for the RR of BMD that was done in GBD 2013. In the GBD 2013 review, twelve prospective observational studies were found, but one meta-analysis of 12 studies[1] reported the dose-response relationship between low BMD and high relative risk of hip and other fractures that are prone to osteoporosis, as shown in the below table.

BMD z score	Any fracture		Osteoporotic fracture		Hip fracture	
	RR	95% CI	RR	95% CI	RR	95% CI
−4	1.79	1.44–2.23	2.10	1.63–2.71	2.14	1.40–3.26
−3	1.71	1.44–2.02	1.96	1.61–2.39	2.12	1.54–2.92
−2	1.63	1.45–1.84	1.84	1.60–2.12	2.11	1.70–2.62
−1	1.56	1.45–1.69	1.73	1.59–1.89	2.11	1.86–2.39
0	1.50	1.44–1.56	1.62	1.54–1.71	2.08	1.91–2.26
1	1.39	1.32–1.46	1.42	1.34–1.51	2.04	1.78–2.34
2	1.32	1.21–1.45	1.33	1.19–1.48	2.03	1.60–2.56
3	1.26	1.10–1.45	1.25	1.06–1.47	2.01	1.44–2.81
4	1.21	1.00–1.45	1.17	0.93–1.46	1.99	1.28–3.10

The z score ranged from −5.1 to +5.8.

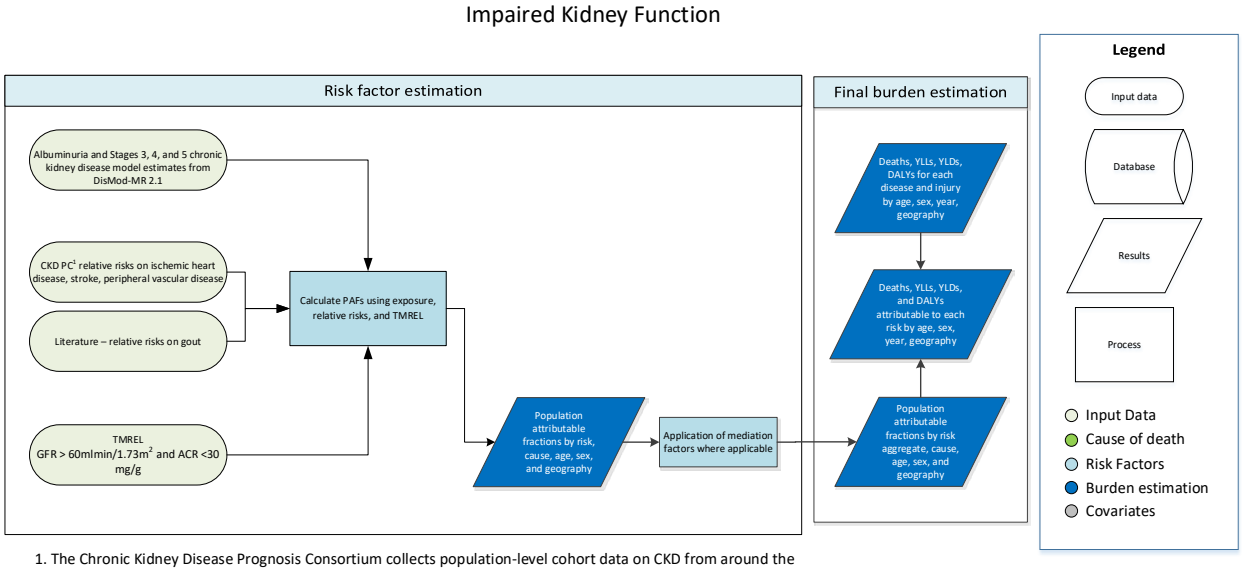
Impaired Kidney Function Capstone Appendix

Flowchart



1. The Chronic Kidney Disease Prognosis Consortium collects population-level cohort data on CKD from around the world for the purpose of collective meta-analyses

Input Data & Methodological Summary

Exposure

Case Definition

The impaired kidney function risk factor exposure is divided into four categories of renal function defined by urinary albumin to creatinine ratio (ACR) and estimated glomerular filtration rate (GFR): albuminuria with preserved GFR (ACR >30 mg/g & GFR >=60 ml/min/1.73m^2), chronic kidney disease (CKD) stage 3 (GFR of 30-59 ml/min/1.73m^2), CKD stage 4 (GFR of 15-29 ml/min/1.73m^2), and CKD stage 5 (GFR <15ml/min/1.73m^2, not yet on renal replacement therapy). The modelling of renal function prevalence estimates is described in detail in the appendix to the GBD 2017 non-fatal capstone paper as these are also disease sequelae.

Input data

For GBD 2010, a systematic review of the prevalence of low glomerular filtration rate throughout the world was conducted. This search was updated for GBD 2013, GBD 2015, and 2016. Exclusion criteria included surveys that were not population-representative, studies not reporting on CKD by stage, and studies not reporting on albuminuria with preserved GFR (GFR >=60 ml/min/1.73m^2).

Disease	Number of sources	Number of countries	Number of new sources for GBD 2016
Albuminuria	72	31	72
CKD Stage III	112	47	49
CKD Stage IV	94	40	45
CKD Stage V	92	38	49

Modeling strategy

Estimates of exposure to albuminuria and CKD were obtained from the GBD 2017 non-fatal burden of disease analysis, which includes stage-specific prevalence estimates at the country level across twenty-three age-groups for both genders. The modeling strategy for these estimates is detailed in the appendix to the GBD 2017 non-fatal capstone paper.

Relative risks were calculated by the Chronic Kidney Disease Prognosis Consortium, a consortium composed of population-level cohorts with prospective data collection from several countries (details below). YLDs and YLLs for cardiovascular diseases and gout were obtained from the GBD 2017 Study for the same geographic, time-period, and age-groups as detailed above.

Theoretical minimum-risk exposure level

The theoretical minimum risk is a diagnosis of albuminuria or CKD stages 3, 4, or 5. An ACR above 30 mg/g and eGFR below 60ml/min/1.73m^2 have been demonstrated in the literature to be the thresholds at which increased cardiovascular and gout events occur secondary to impaired kidney function. (1-10)

Relative risk

A two-stage pooled meta-analysis was used to calculate relative risks for ischemic heart disease, stroke, and peripheral vascular disease. The relative risk of these conditions was first determined within each cohort, and then a pooled analysis of cohort-level relative risks was performed using a random effects meta-analysis approach. Uncertainty intervals largely overlapped for the relative risks of fatal and nonfatal cardiovascular events from impaired kidney function exposure. Thus, we decided to use the relative risks from the combined analysis for fatal and nonfatal cardiovascular outcomes. Gout relative risk was determined by meta-analysis of a literature review performed for GBD 2013. Search terms included “gout” and “chronic kidney disease”. Exclusion criteria for search results included special populations, reversal of exposure and outcome categories, or unclear exposure category definition. This search resulted in four eligible studies; no new studies indicated an increased risk of gout with albuminuria.

Population Attributable Fraction

We calculated the cardiovascular and gout fatal and nonfatal burden attributable to the categorical exposure to impaired kidney function using the following equation:

$$PAF = \frac{\sum_{i=1}^{n} P_i(RR_i - 1)}{\sum_{i=1}^{n} P_i(RR_i - 1) + 1}$$

Equation 1. PAF based on categorical exposure

where RR_i is the relative risk for exposure level *i*, P_i is the proportion of the population in that exposure category, and *n* is the number of exposure categories.(11)

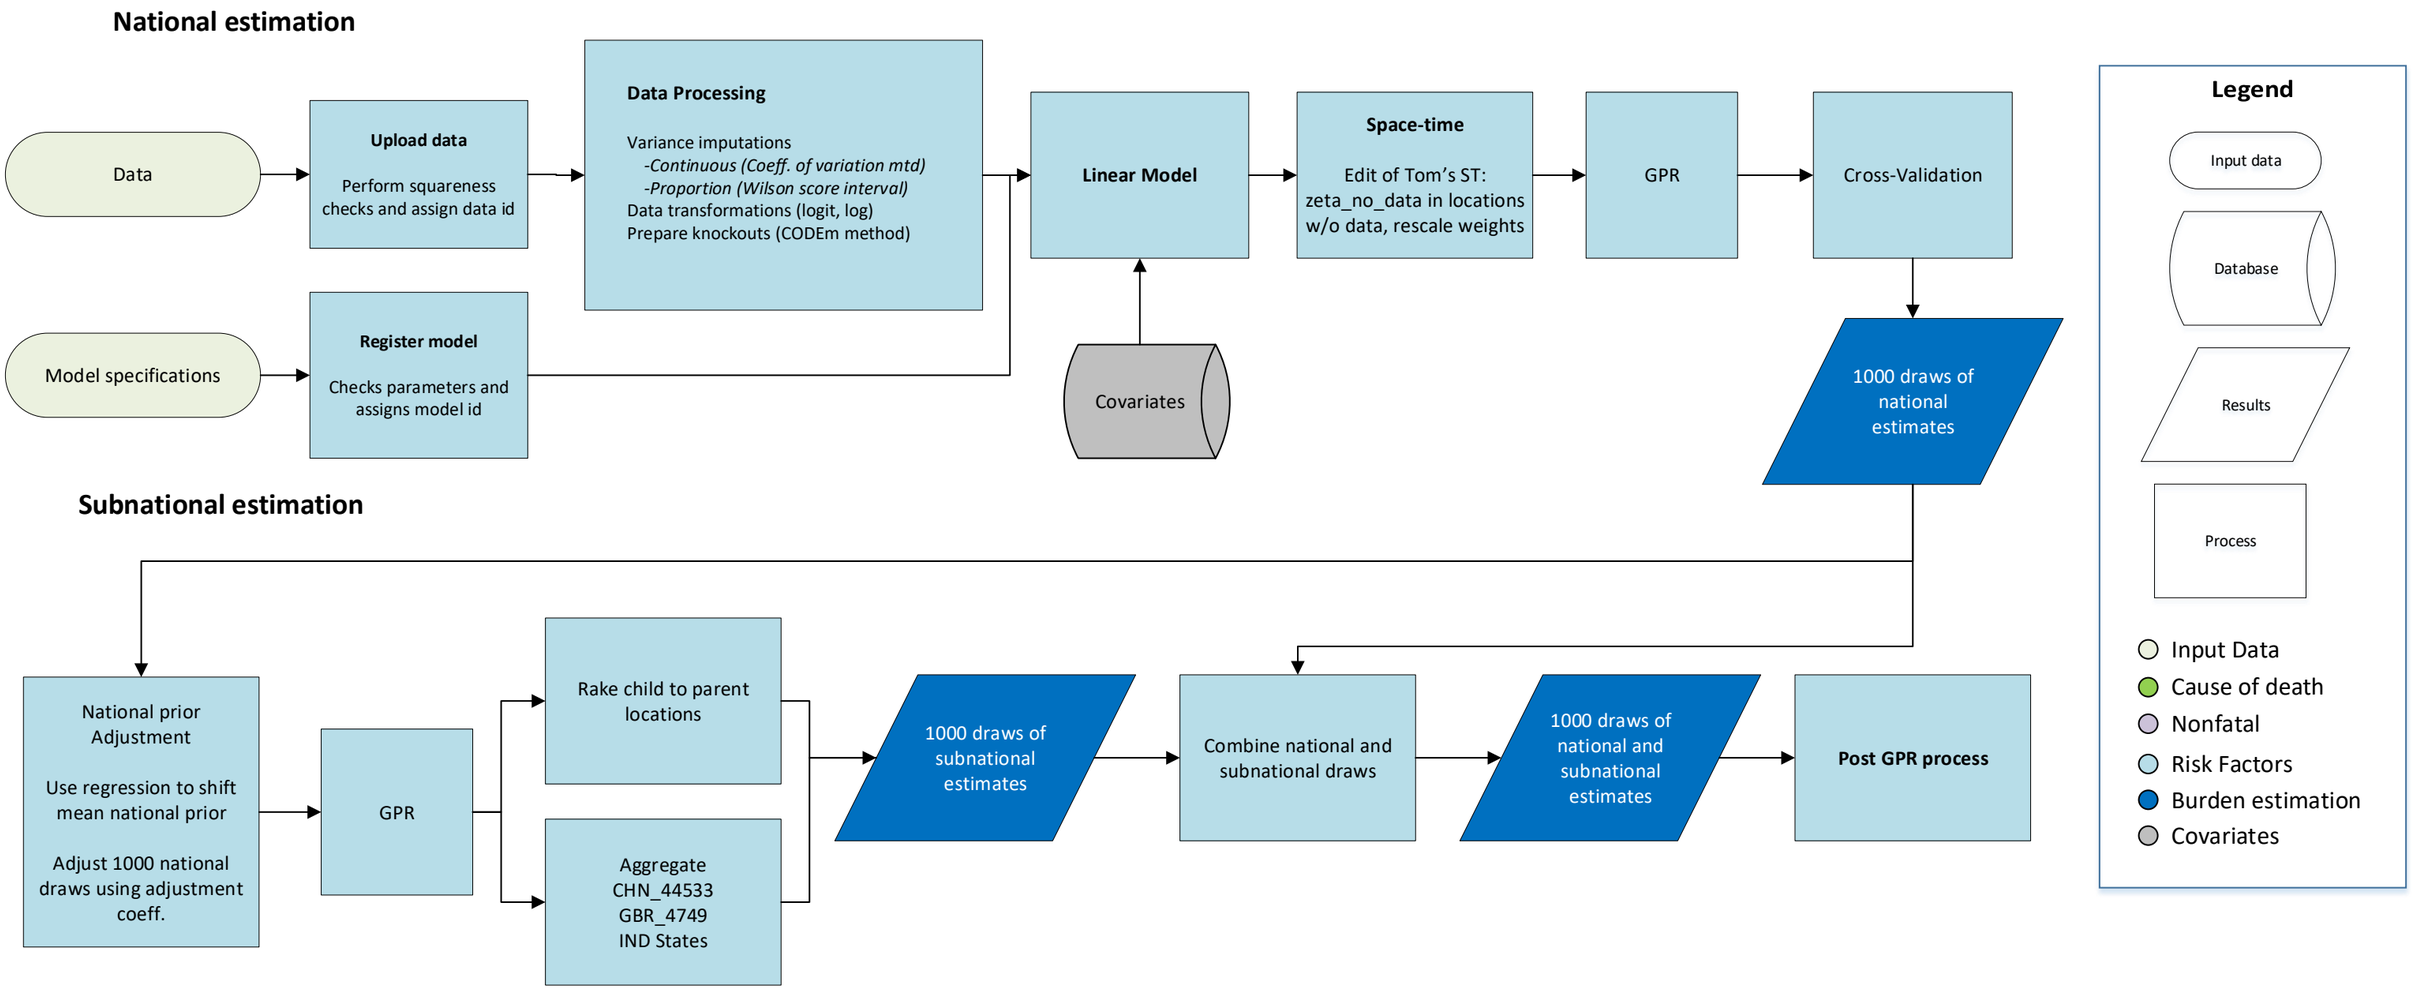
Appendix Figure 3: Spatiotemporal Gaussian Process Regression



Appendix Table 1. GATHER checklist of information that should be included in reports of global health estimates, with description of compliance and location of information for GBD 2017.

#	GATHER checklist item	Description of compliance	Reference
Objectives and funding			
1	Define the indicators, populations, and time periods for which estimates were made.	Narrative provided in paper and methods appendix describing indicators, definitions, and populations	Main text (Methods—Overview, Geographic units and time periods) and methods appendix
2	List the funding sources for the work.	Funding sources listed in paper	Summary (Funding)
Data Inputs			
For all data inputs from multiple sources that are synthesized as part of the study:			
3	Describe how the data were identified and how the data were accessed.	Narrative description of data seeking methods provided	Main text (Methods) and methods appendix
4	Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions.	Narrative about inclusion and exclusion criteria by data type provided	Main text (Methods) and methods appendix
5	Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant.	An interactive, online data source tool that provides metadata for data sources by component, geography, cause, risk, or impairment has been developed	Online data citation tools
6	Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5).	Summary of known biases by cause included in methods appendix	Methods appendix
For data inputs that contribute to the analysis but were not synthesized as part of the study:			
7	Describe and give sources for any other data inputs.	Included in online data source tool, http://ghdx.healthdata.org/gbd-2017	Online data citation tools
For all data inputs:			
8	Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet as opposed to a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be shared due to ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data.	Downloads of input data available through online tools, including data visualization tools and data query tools, http://ghdx.healthdata.	Online data visualization tools, data query tools, and the Global Health Data Exchange, http://ghdx.healthdata.org

		org/gbd-2017; input data not available in tools will be made available upon request	
Data analysis			
9	Provide a conceptual overview of the data analysis method. A diagram may be helpful.	Flow diagrams of the overall methodological processes, as well as cause-specific modelling processes, have been provided	Main text (Methods) and methods appendix
10	Provide a detailed description of all steps of the analysis, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s).	Flow diagrams and corresponding methodological write-ups for each cause, as well as the demographics and causes of death databases and modelling processes, have been provided	Main text (Methods) and methods appendix
11	Describe how candidate models were evaluated and how the final model(s) were selected.	Provided in the methodological write-ups	Methods appendix
12	Provide the results of an evaluation of model performance, if done, as well as the results of any relevant sensitivity analysis.	Provided in the methodological write-ups	Methods appendix
13	Describe methods for calculating uncertainty of the estimates. State which sources of uncertainty were, and were not, accounted for in the uncertainty analysis.	Provided in the methodological write-ups	Methods appendix
14	State how analytic or statistical source code used to generate estimates can be accessed.	Access statement provided	Code is provided in an online repository
Results and Discussion			
15	Provide published estimates in a file format from which data can be efficiently extracted.	Results are available through online data visualization tools, the Global Health Data Exchange, and the online data query tool (http://ghdx.healthdata.org/gbd-2017)	Main text, methods appendix, and online data tools (data visualization tools, data query tools, and the Global Health Data Exchange, http://ghdx.healthdata.org/gbd-2017)
16	Report a quantitative measure of the uncertainty of the estimates (e.g. uncertainty intervals).	Uncertainty intervals are provided with all results	Main text, methods appendix, and online data tools (data visualization tools, data query tools, and the

			Global Health Data Exchange, http://ghdx.healthdata.org/gbd-2017)
17	Interpret results in light of existing evidence. If updating a previous set of estimates, describe the reasons for changes in estimates.	Discussion of methodological changes between GBD rounds provided in the narrative of the Article and methods appendix	Main text (Methods and Discussion) and methods appendix
18	Discuss limitations of the estimates. Include a discussion of any modelling assumptions or data limitations that affect interpretation of the estimates.	Discussion of limitations provided in the narrative of the main paper, as well as in the methodological write-ups in the methods appendix	Main text (Limitations) and methods appendix

Appendix Table 2. GBD 2017 risk factor hierarchy with levels, modeling strategies, and the main type of data sources used to estimate exposure levels
GBD=Global Burden of Disease.

Risk factor	Level	Model type	Main data source for exposure
All risk factors	**0**		
Environmental/occupational risks	**1**		
Unsafe water, sanitation, and handwashing	**2**		
Unsafe water source	3	Spatiotemporal Gaussian process regression (ST-GPR)	Population surveys and censuses
Unsafe sanitation	3	ST-GPR	Population surveys and censuses
No handwashing with soap	3	ST-GPR	Population surveys, censuses, and epidemiological studies
Air pollution	**2**		
Particulate matter pollution	3		
Ambient particulate matter pollution	4	Regression crosswalk between grid-level fusion of satellite/chemical transport models and ground level monitoring data	Atmospheric chemical transport models, satellite measurements of aerosols in the atmosphere, data from ground-level monitoring sites
Household air pollution from solid fuels	4	ST-GPR	Population surveys and censuses
Ambient ozone pollution	3	Chemical transport model	Atmospheric chemical transport models
Other environmental risks	**2**		
Residential radon	3	ST-GPR	Literature review
Lead exposure	3	ST-GPR	Literature review
Occupational risks	**2**		
Occupational carcinogens	3		
Occupational exposure to asbestos	4	Asbestos Impact Ratio approach	GBD cause-specific mortality data for mesothelioma, epidemiological studies
Occupational exposure to arsenic	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to benzene	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to beryllium	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to cadmium	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to chromium	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to diesel engine exhaust	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to formaldehyde	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to nickel	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to polycyclic aromatic hydrocarbons	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to silica	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to sulfphuric acid	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational exposure to trichloroethylene	4	ST-GPR	Labor force surveys, censuses, and international information system on occupational exposure to carcinogens
Occupational asthmagens	3	ST-GPR	Labor force surveys and censuses
Occupational particulate matter, gases, and fumes	3	ST-GPR	Labor force surveys and censuses
Occupational noise	3	ST-GPR	Labor force surveys and censuses, industry-based surveys of noise exposure
Occupational injuries	3	ST-GPR	International Labor Organization injury database
Occupational ergonomic factors	3	ST-GPR	Labor force surveys and censuses
Behavioural risks	**1**		
Child and maternal malnutrition	**2**		
Suboptimal breastfeeding	3		
Non-exclusive breastfeeding	4	ST-GPR	Population surveys
Discontinued breastfeeding	4	ST-GPR	Population surveys
Childhood undernutrition	3		
Childhood underweight	4	ST-GPR	Examination surveys and epidemiological studies
Childhood wasting	4	ST-GPR	Examination surveys and epidemiological studies
Childhood stunting	4	ST-GPR	Examination surveys and epidemiological studies
Iron deficiency	3	Mixed effect regression	Examination surveys and epidemiological studies
Vitamin A deficiency	3	DisMod-MR 2.1	Examination surveys and epidemiological studies
Zinc deficiency	3	Mixed effect regression based on stunting prevalence and dietary composition	FAO food balance sheets
Tobacco smoke	**2**		
Smoking	3	• Smoking Impact Ratio (SIR) calculated from lung cancer mortality rates • Smoking prevalence estimated using ST-GPR	SIR input data: mortality and cause of death data including vital registration and verbal autopsy Smoking prevalence input data: nationally representative survey and report data
Second-hand smoke	3	DisMod-MR 2.1	Household surveys and national health surveys

Risk factor	Level	Model type	Main data source for exposure
Alcohol use	**2**	• Alcohol consumption per capita obtained from the FAO and the WHO Global Information System on Alcohol and Health (GISAH) • ST-GPR used to integrate the data and to derive coherent time series for each country • Prevalence of current alcohol drinkers, lifetime abstainers, former drinkers, and binge drinkers estimated using DisMod-MR 2.1 • DisMod-MR 2.1 used to estimate the relative sex- and age-specific pattern of alcohol consumption in current drinkers	Population surveys, alcohol sales, production, and other economic statistics
Drug Use	**2**	DisMod-MR 2.1	Systematic review of published literature, reports from governments and international organizations, which include data from: school surveys, population surveys, registration data, and indirect estimates of prevalence
Dietary risks	**2**		
Diet low in fruits	3	DisMod-MR 2.1	Nutrition and health surveys, FAO food balance sheets
Diet low in vegetables	3	DisMod-MR 2.1	Nutrition and health surveys, FAO food balance sheets
Diet low in whole grains	3	DisMod-MR 2.1	Nutrition and health surveys
Diet low in nuts and seeds	3	DisMod-MR 2.1	Nutrition and health surveys, FAO food balance sheets
Diet low in milk	3	DisMod-MR 2.1	Nutrition and health surveys, FAO food balance sheets
Diet high in red meat	3	DisMod-MR 2.1	Nutrition and health surveys, FAO food balance sheets
Diet high in processed meat	3	DisMod-MR 2.1	Nutrition and health surveys
Diet high in sugar-sweetened beverages	3	DisMod-MR 2.1	Nutrition and health surveys
Diet low in fibre	3	DisMod-MR 2.1	Nutrition and health surveys, FAO SUA/USDA
Diet suboptimal in calcium	3	DisMod-MR 2.1	Nutrition and health surveys, FAO SUA/USDA
Diet low in seafood omega-3 fatty acids	3	DisMod-MR 2.1	Nutrition and health surveys, FAO SUA/USDA
Diet low in polyunsaturated fatty acids	3	DisMod-MR 2.1	Nutrition and health surveys, FAO SUA/USDA
Diet high in trans fatty acids	3	DisMod-MR 2.1	Nutrition and health surveys
Diet high in sodium	3	DisMod-MR 2.1	Nutrition and health surveys
Intimate partner violence	**2**	DisMod-MR 2.1	Systematic review of published literature, national health surveys, violence-specific surveys
Childhood maltreatment	**2**		
Childhood sexual abuse	3	DisMod-MR 2.1	Systematic review of published literature, national health surveys, violence-specific surveys
Bullying victimization	3	DisMod-MR 2.1	Systematic review of published literature and surveys reporting bullying victimization, including Global School-based Student Health Survey (GSHS), the Health Behavior in School-aged Children (HBSC), and the National Crime Victimization Survey – School Crime Supplement (NCVS-SCS).
Unsafe sex	2	DisMod-MR 2.1	UNAIDS country progress reports, disease surveillance reports
Low physical activity	2	DisMod-MR 2.1	Surveys of the adult population that capture reported frequency, duration and intensity of physical activity undertaken in the past seven days across all domains of life (work, transport, recreation or house/yard work)
Metabolic risks	**1**		
High fasting plasma glucose	2	ST-GPR	Examination surveys and epidemiological studies
High LDL cholesterol	2	ST-GPR	Examination surveys and epidemiological studies
High systolic blood pressure	2	ST-GPR	Examination surveys and epidemiological studies
High body-mass index	2	ST-GPR	Examination surveys and epidemiological studies
Low bone mineral density	2	DisMod-MR 2.1	Examination surveys and epidemiological studies
Low glomerular filtration rate	2	DisMod-MR 2.1	Examination surveys and epidemiological studies

Appendix Table 3. Types of Comparative Risk Assessments (CRA) based on the time perspective and the nature of the counterfactual level or distribution of exposure. The shaded box represents the type of CRA currently undertaken in GBD 2017. GBD=Global Burden of Disease.

	Counterfactual distributions of exposure			
Construct	Theoretical minimum risk: level of risk with the lowest level of burden	Plausible minimum risk: level of risk with the lowest level of burden that could be imagined with current technology and knowledge	Feasible minimum risk: level of risk with the lowest level of burden that has been achieved in any population	Cost-effective minimum risk: lowest level of risk that can be achieved cost-effectively in a given population
Attributable burden: burden of disease today that would be avoided if each individual in the past had been exposed to the counterfactual level of exposure	**Currently in GBD**			
Avoidable burden: burden of disease in the future that would be avoided if each individual today was shifted to the counterfactual level of exposure				

Appendix Table 4. Descriptive cataloguing of the epidemiological evidence used to assess whether each risk-outcome paper meets the causal criteria for inclusion in the Global Burden of Disease

Risk Level	Risk	Outcome	RCTs (n)	RCTs with significant effect in the opposite direction (%)	RCTs with null findings (%)	Prospective observational studies (n)*	Prospective observational studies with significant association in the opposite direction (%)	Case-control studies assessing the risk-outcome pair relationship (n)**	Case-control studies that show significant association in the opposite direction (%)	Lower limit of RR > 1.5	Dose-response relationship	Biological plausibility †	Analogy ‡
2	**Unsafe water, sanitation, and handwashing**												
3	Unsafe water source - chlorination or solar (point of use treatment)	Diarrhoeal diseases	25	0	44	6	0	-	-	Yes	-	Yes	No
3	Unsafe water source - piped	Diarrhoeal diseases	1	0	0	9	11	-	-	Yes	-	Yes	No

Risk	Outcome	Citation/Note
6B. Supplemental information		
"RCTs (Number)" represents the total number of independent randomized controlled trials evaluating the relationship of each risk-outcome pair. "RCTs with significant effect in the opposite direction (%)" represents the percentage of randomized controlled trials showing a significant effect in the opposite direction. "Prospective observational studies (Number)" shows the total number of independent prospective cohort studies or non-randomized interventions evaluating the relationship of the risk-outcome pair. "Prospective observational studies with significant association in the opposite direction (%)" represents the percentage of prospective cohort studies or non-randomized interventions reporting a significant association in the opposite direction. "Lower limit of RR > 1.5" shows whether the lower limit of the 95% confidence interval for the relative risk of the risk-outcome pair is greater than 1.5. "Dose-response relationship" shows whether there is any evidence of linear or non-linear dose-response relationship between the risk and the outcome. "Biologic plausibility" shows whether there is any biologic or mechanistic pathway that could potentially explain the relationship of the risk-outcome pair. "Analogy" shows whether the risk is associated with another outcome from the same category and there is evidence that it can cause the current outcome through the same pathway. The numbers in the table represent the independent RCTs and prospective observational studies evaluated the relationship between each risk-outcome pairs. If there were multiple reports from one study, they were counted as one study. Dose-response relationship was only assessed for continuous risks. To evaluate the magnitude of the effect size for continuous risks, we evaluated the RR comparing the 75th percentile to the 25th percentile of the exposure distribution at the global level .		
Unsafe water, sanitation, and handwashing	Typhoid and paratyphoid fever	Typhoid and paratyphoid were included as outcome for unsafe water and sanitation by analogy to diarrhoeal diseases
Household air pollution from solid fuels	Cataract	Evidence on the relationship between household air pollution and cataract was from 6 case-control and 1 cross-sectional studies
Air pollution	--	The relationships of cerebrovascular disease, chronic obstructive pulmonary disease, ischaemic heart disease, and lung cancer with ambient air pollution, second-hand smoke, and active smoking were used to interpolate their relationship with household air pollution. We considered the biological pathway for health impact of all four sources to be PM2.5 exposure, with the effect size being a function of the level of PM2.5. As such, we presented data from cohorts reporting on ambient PM2.5 and the outcome was used to inform the strength of evidence for household air pollution.
Other environmental risks and dietary risks	Cardiovascular diseases and chronic kidney disease	The health effects of lead and sodium on cardiovascular outcomes and chronic kidney disease were assessed through systolic blood pressure and the health effects of sugar sweetened beverages were assessed through body mass index.
Residential Radon	Tracheal, bronchus, and lung cancer	In evaluation of evidence on the relationship of residential radon and lung cancer, we excluded evidence from cohorts of miners as they were not from a representative population. Evidence on this risk-outcome pair mostly comes from case-control studies
Occupational injuries	Injuries	Evidence from International Labour Organization Safety and Health and Eurostat Safety and Health was used to establish causality between occupational injuries and injuries
Child and maternal malnutrition	--	Evidence on the causal relationship of childhood stunting, underweight, and wasting was from a pooled analysis of 7 prospective cohorts
Child and maternal malnutrition	--	For the following risk-outcome pairs, the risk factor was considered as the necessary cause: childhood underweight and protein-energy malnutrition; childhood wasting and protein-energy malnutrition; vitamin A deficiency and vitamin A deficiency; alcohol use and cirrhosis due to alcohol use; alcohol use and alcohol use disorders; alcohol use and liver cancer due to alcohol use; drug use and amphetamine use disorders; drug use and cannabis use disorders; drug use and cocaine use disorders; drug use and opioid use disorders; drug use and other drug use disorders; iron deficiency and iron-deficiency anemia; unsafe sex and cervical cancer; unsafe sex and syphilis; unsafe sex and chlamydial infection; unsafe sex and gonococcal infection; unsafe sex and trichomoniasis; unsafe sex and genital herpes; unsafe sex and other sexually transmitted diseases; high systolic blood pressure and hypertensive heart disease; high systolic blood pressure and chronic kidney disease due to hypertension; high fasting plasma glucose and chronic kidney disease due to diabetes mellitus; high fasting plasma glucose and diabetes mellitus; low glomerular filtration rate and chronic kidney disease
Iron deficiency	Maternal haemorrhage	Evidence on the relationship of iron deficiency with maternal haemorrhage and maternal sepsis mainly came 10 observational studies evaluating the association between low hemoglobin and maternal mortality using hospital records
Smoking, alcohol use, and high body mass index	--	For smoking, alcohol use, and high body mass index evidence from risk reduction trials has not been included
Smoking, alcohol use, and high body mass index	Liver cancer	Liver cancer included liver cancer due to alcohol use, hepatitis B, hepatitis C, and other causes
Smoking	Lower respiratory infections	Evidence on the relationship between smoking and lower respiratory infections comes 10 case-control or cross-sectional studies
Smoking, alcohol use	Nasopharynx cancer	The evidence on causal relationship of alcohol and smoking with nasopharynx cancer was from the studies evaluating oral cavity and pharyngeal cancers as outcome
Smoking	Bladder cancer	The evidence on causal relationship of smoking and bladder cancer was based on the studies evaluating the lower urinary tract as outcome
Smoking	Asbestosis	Asbestosis, coal workers pneumoconiosis, other pneumoconiosis, silicosis were included as outcomes for smoking as they were included in the other chronic respiratory diseases category
Alcohol use	Ischaemic heart disease, cerebrovascular disease, hypertensive heart disease, and diabetes mellitus	Alcohol was included as both a protective and harmful risk factor for ischaemic heart disease, cerebrovascular disease, hypertensive heart disease, and diabetes mellitus
Alcohol use	Cirrhosis	Cirrhosis included cirrhosis due to alcohol use, hepatitis B, hepatitis C, and other causes
Alcohol use	Self-harm	Self-harm was included as an outcome for alcohol use by analogy to injury
Alcohol use	Injuries	Injuries included pedestrian road injuries, cyclist road injuries, motorcyclist road injuries, motor vehicle road injuries, drowning, falls, fire, heat, hot substances, poisonings, unintentional firearm injuries, unintentional suffocation, other exposure to mechanical forces
Alcohol use	Interpersonal violence	Interpersonal violence included assault by firearm, sharp object, other means
Diet low in nuts and seeds	Ischaemic heart disease and diabetes mellitus	Experimental evidence on the relationship of nuts with ischaemic heart disease and diabetes mellitus come from the PREDIMED trial; a randomized trial consisting of three arms: a Mediterranean diet with extra-virgin olive oil, a Mediterranean diet with nuts, and a control diet. Given that the intake of dietary factors other than nuts changed in the intervention arms of this trial, the observed effect might be fully attributable to nuts.

Appendix Table 5. Epidemiological evidence supporting causality between risk-outcome pairs included in the Global Burden of Disease 2017 study including A. Citations and B. Additional information

A. Citations

Risk	Outcome	Citation/Note
Diet high in sugar sweetened beverages and body mass index	--	Evidence on the relationship between sugar-sweetened beverages and body mass index comes from the interventional and prospective observational studies evaluating the relationship of sugar-sweetened beverages with weight change among children and adults.
Diet high in sodium	Cardiovascular diseases	Evidence on the direct effect of sodium on cardiovascular disease mainly comes from prospective cohort studies. Considering that, in GBD, we have only evaluated the effect of sodium mediated through systolic blood pressure, we did not present epidemiologic evidence on the direct effect of sodium on cardiovascular disease in this table. Evidence on the effect of sodium on systolic blood pressure mostly comes from randomized controlled trials. While some cohort studies evaluated the relationship between sodium and systolic blood pressure, we did not identify a systematic evaluation of these studies.
Drug use	Hepatitis B and C	We included liver cancer due to Hepatitis B and Hepatitis C and cirrhosis due to Hepatitis B and Hepatitis C as outcomes for drug use because these were considered secondary outcomes of Hepatitis B and Hepatitis C.
Drug use, unsafe sex	HIV/AIDS	For the following risk-outcome pairs, the risk factor was considered as the sufficient cause: drug use and HIV/AIDS and unsafe sex and HIV/AIDS
Metabolic risks	Chronic kidney disease	Chronic kidney disease included chronic kidney disease due to diabetes mellitus, hypertension, glomerulonephritis, or other causes
High fasting plasma glucose	Cerebrovascular disease, chronic kidney disease, ischaemic heart disease	Evidence on the relationship of high fasting plasma glucose with stroke (DECODE, APCSC, ERFC); chronic kidney disease (APCSC), and ischaemic heart disease (DECODE, APCSC, ERFC) was from pooled analysis of cohorts
High systolic blood pressure	Atrial fibrillation and flutter, peripheral vascular disease	Evidence on the relationship of high systolic blood pressure with atrial fibrillation and peripheral vascular disease was from two pooled cohort analysis (APCSC and PSC)
High systolic blood pressure	Rheumatic heart disease, cardiomyopathy and myocarditis, aortic aneurysm, endocarditis, and other cardiovascular diseases	Evidence on the relationship of high systolic blood pressure with rheumatic heart disease, cardiomyopathy and myocarditis, aortic aneurysm, endocarditis, and other cardiovascular diseases came from a pooled cohort analysis (PSC)
High body-mass index	Ischaemic heart disease	Evidence on the relationship of high body-mass index with ischaemic heart disease (APCSC, ERFC, PSC) and stroke (ischaemic: APCSC, ERFC, PSC; hemorrhagic: PSC and ERFC) came from three pooled cohort analysis
High body-mass index	Diabetes mellitus, hypertensive heart disease	Evidence on the relationship of high body-mass index with diabetes mellitus and hypertensive heart disease came from two pooled cohort analysis (APCSC and PSC)
High body-mass index	Chronic kidney disease	Evidence on the relationship of high body-mass index with chronic kidney disease was from a pooled cohort analysis (PSC)
High LDL cholesterol	Ischaemic heart disease, ischaemic stroke	Evidence on the relationship of high LDL cholesterol with ischaemic heart disease and ischaemic stroke came from two pooled cohort analysis (APCSC and PSC)
Impaired kidney function	Tuberculosis	Glycemic Control and the Risk of Tuberculosis: A Cohort Study.

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	Ages																							
				All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years

Lower respiratory infections	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Lower respiratory infections	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Lower respiratory infections	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Lower respiratory infections	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Upper respiratory infections	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Upper respiratory infections	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2111.877)	713.571 (526.178 to 921.018)																					
Upper respiratory infections	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Upper respiratory infections	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Upper respiratory infections	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Upper respiratory infections	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Upper respiratory infections	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Upper respiratory infections	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Upper respiratory infections	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Upper respiratory infections	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Upper respiratory infections	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Upper respiratory infections	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Upper respiratory infections	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
Upper respiratory infections	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
Upper respiratory infections	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
Upper respiratory infections	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
Upper respiratory infections	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
Upper respiratory infections	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
Upper respiratory infections	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
Upper respiratory infections	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Males		57.155 (42.484 to 73.651)	23.114 (19.028 to 27.915)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Females		56.109 (39.794 to 76.295)	25.149 (20.615 to 30.388)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Males		37.444 (29.026 to 48.227)	12.233 (10.252 to 14.477)																					
Upper respiratory infections	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Females		36.874 (26.658 to 49.653)	14.384 (12.095 to 17.03)																					
Upper respiratory infections	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Males		18.092 (13.292 to 23.719)	9.23 (7.037 to 11.454)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																						
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years

Otitis media	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Females		13.266 (9.666 to 17.689)	6.395 (5.292 to 7.606)																					
Otitis media	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Males		23.096 (14.708 to 35.098)	2.895 (2.245 to 3.716)																					
Otitis media	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Females		25.038 (15.763 to 37.255)	3.778 (2.855 to 4.925)																					
Otitis media	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Males		14.006 (10.222 to 18.478)	4.322 (3.449 to 5.338)																					
Otitis media	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Females		14.375 (10.269 to 20.114)	5.265 (4.145 to 6.564)																					
Otitis media	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Males		4.874 (4.014 to 5.713)	3.699 (3.134 to 4.374)																					
Otitis media	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Females		4.609 (3.731 to 5.61)	3.898 (3.235 to 4.67)																					
Otitis media	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Males		18.024 (12.279 to 25.547)	3.657 (2.838 to 4.675)																					
Otitis media	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Females		19.263 (12.567 to 27.924)	4.634 (3.576 to 5.889)																					
Otitis media	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Males		3.306 (2.82 to 3.843)	3.194 (2.691 to 3.803)																					
Otitis media	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Females		2.991 (2.496 to 3.61)	3.242 (2.745 to 3.817)																					
Otitis media	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Males		3.771 (3.002 to 4.693)	3.175 (2.56 to 3.923)																					
Otitis media	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Females		3.244 (2.486 to 4.159)	3.228 (2.605 to 3.985)																					
Otitis media	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Males		2.755 (2.274 to 3.309)	2.944 (2.44 to 3.548)																					
Otitis media	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																					
Otitis media	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																					
Otitis media	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																					
Otitis media	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																					
Otitis media	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																					
Otitis media	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)																					
Otitis media	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Females		4.662 (3.577 to 6.014)	2.398 (1.98 to 2.864)																					
Otitis media	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Males		2.007 (1.759 to 2.293)	1.888 (1.613 to 2.224)																					
Otitis media	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Females		1.925 (1.582 to 2.328)	1.972 (1.669 to 2.313)																					
Otitis media	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Males		3.28 (2.596 to 4.133)	1.335 (1.171 to 1.532)																					
Otitis media	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Females		3.521 (2.649 to 4.5)	1.559 (1.333 to 1.835)																					
Otitis media	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Males		2.128 (1.833 to 2.466)	1.505 (1.299 to 1.76)																					
Otitis media	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Females		2.142 (1.694 to 2.67)	1.661 (1.411 to 1.961)																					
Otitis media	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Males		1.436 (1.245 to 1.65)	1.47 (1.199 to 1.8)																					
Otitis media	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Females		1.326 (1.069 to 1.614)	1.465 (1.188 to 1.775)																					
Otitis media	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Males		1.33 (1.155 to 1.53)	1.559 (1.305 to 1.851)																					
Otitis media	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Females		1.224 (1.0 to 1.492)	1.564 (1.304 to 1.847)																					
Otitis media	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Males		1.787 (1.453 to 2.182)	1.175 (1.005 to 1.371)																					
Otitis media	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Females		1.877 (1.467 to 2.388)	1.224 (1.022 to 1.465)																					
Otitis media	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Males		1.785 (1.478 to 2.147)	1.173 (1.0 to 1.377)																					
Otitis media	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Females		1.892 (1.481 to 2.352)	1.23 (1.03 to 1.46)																					
Otitis media	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Males		1.0 (1.0 to 1.0)	1.003 (1.0 to 1.046)																					
Otitis media	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Females		1.002 (1.0 to 1.013)	1.001 (1.0 to 1.006)																					
Otitis media	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Males		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Otitis media	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Females		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Otitis media	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Males		117.172 (83.895 to 158.056)	27.726 (21.877 to 34.972)																					
Otitis media	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Females		121.682 (84.349 to 171.375)	33.983 (26.101 to 43.404)																					
Otitis media	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Males		77.948 (54.687 to 105.047)	16.608 (12.653 to 21.188)																					
Otitis media	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Females		79.193 (54.099 to 112.236)	20.387 (15.089 to 26.434)																					
Otitis media	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Males		42.199 (29.891 to 57.227)	10.082 (7.777 to 13.056)																					
Otitis media	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Females		42.551 (28.25 to 63.209)	11.989 (9.084 to 15.544)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																					
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Otitis media	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Males		58.722 (42.419 to 78.873)	12.115 (9.518 to 15.521)																					
Otitis media	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Females		59.522 (42.058 to 82.793)	15.364 (11.936 to 19.581)																					
Otitis media	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Males		45.67 (32.014 to 65.531)	8.381 (6.362 to 10.842)																					
Otitis media	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Females		46.104 (30.243 to 66.207)	10.506 (8.041 to 13.513)																					
Otitis media	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Males		36.334 (21.558 to 54.813)	5.698 (4.293 to 7.349)																					
Otitis media	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Females		37.931 (22.692 to 61.276)	6.892 (5.175 to 9.058)																					
Otitis media	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Males		34.016 (23.515 to 48.37)	6.577 (4.934 to 8.436)																					
Otitis media	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Females		34.585 (22.909 to 49.754)	8.314 (6.362 to 10.789)																					
Otitis media	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Males		36.248 (23.158 to 54.67)	5.068 (3.761 to 6.741)																					
Otitis media	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Females		38.098 (23.301 to 59.429)	6.476 (4.666 to 8.689)																					
Otitis media	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Males		166.686 (118.487 to 222.581)	57.535 (45.999 to 71.742)																					
Otitis media	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Females		169.725 (119.017 to 229.008)	63.564 (50.068 to 80.703)																					
Otitis media	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Otitis media	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Otitis media	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Otitis media	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Otitis media	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Otitis media	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Diarrhoeal diseases	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2166.967)	618.595 (458.842 to 812.921)																					
Diarrhoeal diseases	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2313.872)	713.571 (526.178 to 921.018)																					
Diarrhoeal diseases	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Diarrhoeal diseases	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Diarrhoeal diseases	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Diarrhoeal diseases	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Diarrhoeal diseases	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Diarrhoeal diseases	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.629 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Diarrhoeal diseases	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Diarrhoeal diseases	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Diarrhoeal diseases	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Diarrhoeal diseases	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Diarrhoeal diseases	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Diarrhoeal diseases	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Diarrhoeal diseases	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
Diarrhoeal diseases	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
Diarrhoeal diseases	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
Diarrhoeal diseases	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
Diarrhoeal diseases	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
Diarrhoeal diseases	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
Diarrhoeal diseases	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
Diarrhoeal diseases	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)

Pneumococcal meningitis	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Pneumococcal meningitis	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Pneumococcal meningitis	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Pneumococcal meningitis	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Pneumococcal meningitis	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Pneumococcal meningitis	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
H influenzae type B meningitis	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
H influenzae type B meningitis	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2211.872)	713.571 (526.178 to 921.018)																					
H influenzae type B meningitis	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
H influenzae type B meningitis	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
H influenzae type B meningitis	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
H influenzae type B meningitis	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
H influenzae type B meningitis	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
H influenzae type B meningitis	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
H influenzae type B meningitis	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
H influenzae type B meningitis	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
H influenzae type B meningitis	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
H influenzae type B meningitis	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Males		57.155 (42.484 to 73.651)	23.114 (19.028 to 27.915)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Females		56.109 (39.794 to 76.295)	25.149 (20.615 to 30.388)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Males		37.444 (29.026 to 48.227)	12.233 (10.252 to 14.477)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Females		36.874 (26.658 to 49.653)	14.384 (12.095 to 17.03)																					
H influenzae type B meningitis	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Males		18.092 (13.292 to 23.719)	9.23 (7.037 to 11.454)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																						
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
H influenzae type B meningitis	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Females		15.574 (11.516 to 20.778)	9.975 (7.82 to 12.46)																					
H influenzae type B meningitis	Birth prevalence - [38, 40) wks, [2000, 2500) g	Mortality	Males		13.104 (9.829 to 16.99)	8.198 (6.786 to 9.959)																					
H influenzae type B meningitis	Birth prevalence - [38, 40) wks, [2000, 2500) g	Mortality	Females		11.308 (8.389 to 14.38)	8.577 (7.84 to 10.449)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Males		33.063 (24.393 to 43.503)	8.441 (6.822 to 10.431)																					
H influenzae type B meningitis	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Females		32.812 (23.439 to 45.567)	10.398 (8.227 to 13.042)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Males		21.925 (16.365 to 29.433)	9.367 (7.859 to 11.112)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Females		21.297 (15.657 to 28.761)	10.295 (8.548 to 12.273)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Males		13.0 (10.102 to 16.456)	8.096 (6.724 to 9.676)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Females		11.563 (8.865 to 15.11)	8.467 (6.994 to 10.342)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Males		14.401 (10.789 to 18.654)	8.221 (6.917 to 9.923)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Females		13.513 (9.817 to 17.942)	8.654 (7.215 to 10.369)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Males		13.419 (10.387 to 16.819)	5.562 (4.646 to 6.696)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Females		13.266 (9.666 to 17.689)	6.395 (5.292 to 7.606)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Males		23.096 (14.708 to 35.098)	2.895 (2.245 to 3.716)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Females		25.038 (15.763 to 37.255)	3.778 (2.855 to 4.925)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Males		14.006 (10.222 to 18.478)	4.322 (3.449 to 5.338)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Females		14.375 (10.269 to 20.114)	5.265 (4.145 to 6.564)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Males		4.874 (4.014 to 5.713)	3.699 (3.134 to 4.374)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Females		4.609 (3.731 to 5.61)	3.898 (3.235 to 4.67)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Males		18.024 (12.279 to 25.547)	3.657 (2.838 to 4.675)																					
H influenzae type B meningitis	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Females		19.263 (12.567 to 27.924)	4.634 (3.576 to 5.889)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Males		3.306 (2.82 to 3.843)	3.194 (2.691 to 3.803)																					
H influenzae type B meningitis	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Females		2.991 (2.496 to 3.61)	3.242 (2.745 to 3.817)																					
H influenzae type B meningitis	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Males		3.771 (3.002 to 4.693)	3.175 (2.56 to 3.923)																					
H influenzae type B meningitis	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Females		3.244 (2.486 to 4.159)	3.228 (2.605 to 3.985)																					
H influenzae type B meningitis	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Males		2.755 (2.274 to 3.309)	2.944 (2.44 to 3.548)																					
H influenzae type B meningitis	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																					
H influenzae type B meningitis	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)

Meningococcal infection	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Females		32.812 (23.439 to 45.567)	10.398 (8.227 to 13.042)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Males		21.925 (16.365 to 29.433)	9.367 (7.859 to 11.112)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Females		21.297 (15.657 to 28.761)	10.295 (8.548 to 12.273)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Males		13.0 (10.102 to 16.456)	8.096 (6.724 to 9.676)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Females		11.563 (8.865 to 15.11)	8.467 (6.994 to 10.342)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Males		14.401 (10.789 to 18.654)	8.221 (6.917 to 9.923)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Females		13.513 (9.817 to 17.942)	8.654 (7.215 to 10.369)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Males		13.419 (10.387 to 16.819)	5.562 (4.646 to 6.696)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Females		13.266 (9.666 to 17.689)	6.395 (5.292 to 7.606)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Males		23.096 (14.708 to 35.098)	2.895 (2.245 to 3.716)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Females		25.038 (15.763 to 37.255)	3.778 (2.855 to 4.925)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Males		14.006 (10.222 to 18.478)	4.322 (3.449 to 5.338)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Females		14.375 (10.269 to 20.114)	5.265 (4.145 to 6.564)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Males		4.874 (4.014 to 5.713)	3.699 (3.134 to 4.374)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Females		4.609 (3.731 to 5.61)	3.898 (3.235 to 4.67)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Males		18.024 (12.279 to 25.547)	3.657 (2.838 to 4.675)																					
Meningococcal infection	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Females		19.263 (12.567 to 27.924)	4.634 (3.576 to 5.889)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Males		3.306 (2.82 to 3.843)	3.194 (2.691 to 3.803)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Females		2.991 (2.496 to 3.61)	3.242 (2.745 to 3.817)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Males		3.771 (3.002 to 4.693)	3.175 (2.56 to 3.923)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Females		3.244 (2.486 to 4.159)	3.228 (2.605 to 3.985)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Males		2.755 (2.274 to 3.309)	2.944 (2.44 to 3.548)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Females		4.662 (3.577 to 6.014)	2.398 (1.98 to 2.864)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Males		2.007 (1.759 to 2.293)	1.888 (1.613 to 2.224)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Females		1.925 (1.582 to 2.328)	1.972 (1.669 to 2.313)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Males		3.28 (2.596 to 4.133)	1.335 (1.171 to 1.532)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Females		3.521 (2.649 to 4.5)	1.559 (1.333 to 1.835)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Males		2.128 (1.833 to 2.466)	1.505 (1.299 to 1.76)																					
Meningococcal infection	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Females		2.142 (1.694 to 2.67)	1.661 (1.411 to 1.961)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Males		1.436 (1.245 to 1.65)	1.47 (1.199 to 1.8)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Females		1.326 (1.069 to 1.614)	1.465 (1.188 to 1.775)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Males		1.33 (1.155 to 1.53)	1.559 (1.305 to 1.851)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Females		1.224 (1.0 to 1.492)	1.564 (1.304 to 1.847)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Males		1.787 (1.453 to 2.182)	1.175 (1.005 to 1.371)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Females		1.877 (1.467 to 2.388)	1.224 (1.022 to 1.465)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Males		1.785 (1.478 to 2.147)	1.173 (1.0 to 1.377)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Females		1.892 (1.481 to 2.352)	1.23 (1.03 to 1.46)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Males		1.0 (1.0 to 1.0)	1.003 (1.0 to 1.046)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Females		1.002 (1.0 to 1.013)	1.001 (1.0 to 1.006)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Males		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Females		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Males		117.172 (83.895 to 158.056)	27.726 (21.877 to 34.972)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Females		121.682 (84.349 to 171.375)	33.983 (26.101 to 43.404)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Males		77.948 (54.687 to 105.047)	16.608 (12.653 to 21.188)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Females		79.193 (54.099 to 112.236)	20.387 (15.089 to 26.434)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Males		42.199 (29.891 to 57.227)	10.082 (7.777 to 13.056)																					
Meningococcal infection	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Females		42.551 (28.25 to 63.209)	11.989 (9.084 to 15.544)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																					
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Meningococcal infection	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Males		58.722 (42.419 to 78.873)	12.115 (9.518 to 15.521)																					
Meningococcal infection	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Females		59.522 (42.058 to 82.793)	15.364 (11.936 to 19.581)																					
Meningococcal infection	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Males		45.67 (32.014 to 65.531)	8.381 (6.362 to 10.842)																					
Meningococcal infection	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Females		46.104 (30.243 to 66.207)	10.506 (8.041 to 13.513)																					
Meningococcal infection	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Males		36.334 (21.558 to 54.813)	5.698 (4.293 to 7.349)																					
Meningococcal infection	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Females		37.931 (22.692 to 61.276)	6.892 (5.175 to 9.058)																					
Meningococcal infection	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Males		34.016 (23.515 to 48.37)	6.577 (4.934 to 8.436)																					
Meningococcal infection	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Females		34.585 (22.909 to 49.754)	8.314 (6.362 to 10.789)																					
Meningococcal infection	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Males		36.248 (23.158 to 54.67)	5.068 (3.761 to 6.741)																					
Meningococcal infection	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Females		38.098 (23.301 to 59.429)	6.476 (4.666 to 8.689)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Males		166.686 (118.487 to 222.581)	57.535 (45.999 to 71.742)																					
Meningococcal infection	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Females		169.725 (119.017 to 229.008)	63.564 (50.068 to 80.703)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Meningococcal infection	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Meningococcal infection	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Other meningitis	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Other meningitis	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2311.877)	713.571 (526.178 to 921.018)																					
Other meningitis	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Other meningitis	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Other meningitis	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Other meningitis	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Other meningitis	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Other meningitis	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Other meningitis	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Other meningitis	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Other meningitis	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Other meningitis	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Other meningitis	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Other meningitis	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Other meningitis	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Other meningitis	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Other meningitis	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Other meningitis	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Other meningitis	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Other meningitis	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Other meningitis	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Other meningitis	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Other meningitis	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Other meningitis	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)

Encephalitis	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Neonatal preterm birth	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Neonatal preterm birth	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2111.877)	713.571 (526.178 to 921.018)																					
Neonatal preterm birth	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Neonatal preterm birth	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Neonatal preterm birth	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Neonatal preterm birth	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Neonatal preterm birth	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Neonatal preterm birth	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Neonatal preterm birth	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Neonatal preterm birth	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Neonatal preterm birth	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Neonatal preterm birth	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Neonatal preterm birth	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
Neonatal preterm birth	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
Neonatal preterm birth	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
Neonatal preterm birth	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
Neonatal preterm birth	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
Neonatal preterm birth	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
Neonatal preterm birth	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
Neonatal preterm birth	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Males		57.155 (42.484 to 73.651)	23.114 (19.028 to 27.915)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Females		56.109 (39.794 to 76.295)	25.149 (20.615 to 30.388)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Males		37.444 (29.026 to 48.227)	12.233 (10.252 to 14.477)																					
Neonatal preterm birth	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Females		36.874 (26.658 to 49.653)	14.384 (12.095 to 17.03)																					
Neonatal preterm birth	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Males		18.092 (13.292 to 23.719)	9.23 (7.037 to 11.454)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																						
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years

Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Females		32.812 (23.439 to 45.567)	10.398 (8.227 to 13.042)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Males		21.925 (16.365 to 29.433)	9.367 (7.859 to 11.112)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Females		21.297 (15.657 to 28.761)	10.295 (8.548 to 12.273)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Males		13.0 (10.102 to 16.456)	8.096 (6.724 to 9.676)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Females		11.563 (8.865 to 15.11)	8.467 (6.994 to 10.342)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Males		14.401 (10.789 to 18.654)	8.221 (6.917 to 9.923)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Females		13.513 (9.817 to 17.942)	8.654 (7.215 to 10.369)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Males		13.419 (10.387 to 16.819)	5.562 (4.646 to 6.696)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Females		13.266 (9.666 to 17.689)	6.395 (5.292 to 7.606)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Males		23.096 (14.708 to 35.098)	2.895 (2.245 to 3.716)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Females		25.038 (15.763 to 37.255)	3.778 (2.855 to 4.925)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Males		14.006 (10.222 to 18.478)	4.322 (3.449 to 5.338)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Females		14.375 (10.269 to 20.114)	5.265 (4.145 to 6.564)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Males		4.874 (4.014 to 5.713)	3.699 (3.134 to 4.374)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Females		4.609 (3.731 to 5.61)	3.898 (3.235 to 4.67)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Males		18.024 (12.279 to 25.547)	3.657 (2.838 to 4.675)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Females		19.263 (12.567 to 27.924)	4.634 (3.576 to 5.889)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Males		3.306 (2.82 to 3.843)	3.194 (2.691 to 3.803)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Females		2.991 (2.496 to 3.61)	3.242 (2.745 to 3.817)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Males		3.771 (3.002 to 4.693)	3.175 (2.56 to 3.923)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Females		3.244 (2.486 to 4.159)	3.228 (2.605 to 3.985)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Males		2.755 (2.274 to 3.309)	2.944 (2.44 to 3.548)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Females		4.662 (3.577 to 6.014)	2.398 (1.98 to 2.864)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Males		2.007 (1.759 to 2.293)	1.888 (1.613 to 2.224)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Females		1.925 (1.582 to 2.328)	1.972 (1.669 to 2.313)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Males		3.28 (2.596 to 4.133)	1.335 (1.171 to 1.532)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Females		3.521 (2.649 to 4.5)	1.559 (1.333 to 1.835)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Males		2.128 (1.833 to 2.466)	1.505 (1.299 to 1.76)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Females		2.142 (1.694 to 2.67)	1.661 (1.411 to 1.961)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Males		1.436 (1.245 to 1.65)	1.47 (1.199 to 1.8)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Females		1.326 (1.069 to 1.614)	1.465 (1.188 to 1.775)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Males		1.33 (1.155 to 1.53)	1.559 (1.305 to 1.851)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Females		1.224 (1.0 to 1.492)	1.564 (1.304 to 1.847)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Males		1.787 (1.453 to 2.182)	1.175 (1.005 to 1.371)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Females		1.877 (1.467 to 2.388)	1.224 (1.022 to 1.465)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Males		1.785 (1.478 to 2.147)	1.173 (1.0 to 1.377)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Females		1.892 (1.481 to 2.352)	1.23 (1.03 to 1.46)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Males		1.0 (1.0 to 1.0)	1.003 (1.0 to 1.046)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Females		1.002 (1.0 to 1.013)	1.001 (1.0 to 1.006)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Males		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Females		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Males		117.172 (83.895 to 158.056)	27.726 (21.877 to 34.972)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Females		121.682 (84.349 to 171.375)	33.983 (26.101 to 43.404)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Males		77.948 (54.687 to 105.047)	16.608 (12.653 to 21.188)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Females		79.193 (54.099 to 112.236)	20.387 (15.089 to 26.434)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Males		42.199 (29.891 to 57.227)	10.082 (7.777 to 13.056)																				
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Females		42.551 (28.25 to 63.209)	11.989 (9.084 to 15.544)																				

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																					
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Males		58.722 (42.419 to 78.873)	12.115 (9.518 to 15.521)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Females		59.522 (42.058 to 82.793)	15.364 (11.936 to 19.581)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Males		45.67 (32.014 to 65.531)	8.381 (6.362 to 10.842)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Females		46.104 (30.243 to 66.207)	10.506 (8.041 to 13.513)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Males		36.334 (21.558 to 54.813)	5.698 (4.293 to 7.349)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Females		37.931 (22.692 to 61.276)	6.892 (5.175 to 9.058)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Males		34.016 (23.515 to 48.37)	6.577 (4.934 to 8.436)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Females		34.585 (22.909 to 49.754)	8.314 (6.362 to 10.789)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Males		36.248 (23.158 to 54.67)	5.068 (3.761 to 6.741)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Females		38.098 (23.301 to 59.429)	6.476 (4.666 to 8.689)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Males		166.686 (118.487 to 222.581)	57.535 (45.999 to 71.742)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Females		169.725 (119.017 to 229.008)	63.564 (50.068 to 80.703)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Neonatal encephalopathy due to birth asphyxia and trauma	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2211.872)	713.571 (526.178 to 921.018)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)

Neonatal sepsis and other neonatal infections	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Females		34.585 (22.909 to 49.754)	8.314 (6.362 to 10.789)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Males		36.248 (23.158 to 54.67)	5.068 (3.761 to 6.741)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Females		38.098 (23.301 to 59.429)	6.476 (4.666 to 8.689)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Males		166.686 (118.487 to 222.581)	57.535 (45.999 to 71.742)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Females		169.725 (119.017 to 229.008)	63.564 (50.068 to 80.703)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Neonatal sepsis and other neonatal infections	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2211.872)	713.571 (526.178 to 921.018)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (702.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Males		57.155 (42.484 to 73.651)	23.114 (19.028 to 27.915)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [1500, 2000) g	Mortality	Females		56.101 (39.794 to 76.295)	25.149 (20.615 to 30.388)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Males		37.444 (29.026 to 48.227)	12.233 (10.252 to 14.477)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [2000, 2500) g	Mortality	Females		36.874 (26.658 to 49.653)	14.384 (12.095 to 17.03)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Males		18.092 (13.292 to 23.719)	9.23 (7.037 to 11.454)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																					
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [2000, 2500) g	Mortality	Females		15.574 (11.516 to 20.778)	9.975 (7.82 to 12.46)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [38, 40) wks, [2000, 2500) g	Mortality	Males		13.104 (9.829 to 16.99)	8.198 (6.786 to 9.959)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [38, 40) wks, [2000, 2500) g	Mortality	Females		11.308 (8.389 to 14.38)	8.577 (7.84 to 10.449)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Males		33.063 (24.393 to 43.503)	8.441 (6.822 to 10.431)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [32, 34) wks, [2500, 3000) g	Mortality	Females		32.812 (23.439 to 45.567)	10.398 (8.227 to 13.042)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Males		21.925 (16.365 to 29.433)	9.367 (7.859 to 11.112)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [2000, 2500) g	Mortality	Females		21.297 (15.657 to 28.761)	10.295 (8.548 to 12.273)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Males		13.0 (10.102 to 16.456)	8.096 (6.724 to 9.676)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [2000, 2500) g	Mortality	Females		11.563 (8.865 to 15.11)	8.467 (6.994 to 10.342)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Males		14.401 (10.789 to 18.654)	8.221 (6.917 to 9.923)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [2000, 2500) g	Mortality	Females		13.513 (9.817 to 17.942)	8.654 (7.215 to 10.369)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Males		13.419 (10.387 to 16.819)	5.562 (4.646 to 6.696)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [2500, 3000) g	Mortality	Females		13.266 (9.666 to 17.689)	6.395 (5.292 to 7.606)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Males		23.096 (14.708 to 35.098)	2.895 (2.245 to 3.716)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [4000, 4500) g	Mortality	Females		25.038 (15.763 to 37.255)	3.778 (2.855 to 4.925)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Males		14.006 (10.222 to 18.478)	4.322 (3.449 to 5.338)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [3000, 3500) g	Mortality	Females		14.375 (10.269 to 20.114)	5.265 (4.145 to 6.564)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Males		4.874 (4.014 to 5.713)	3.699 (3.134 to 4.374)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [2500, 3000) g	Mortality	Females		4.609 (3.731 to 5.61)	3.898 (3.235 to 4.67)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Males		18.024 (12.279 to 25.547)	3.657 (2.838 to 4.675)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [34, 36) wks, [3500, 4000) g	Mortality	Females		19.263 (12.567 to 27.924)	4.634 (3.576 to 5.889)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Males		3.306 (2.82 to 3.843)	3.194 (2.691 to 3.803)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [2500, 3000) g	Mortality	Females		2.991 (2.496 to 3.61)	3.242 (2.745 to 3.817)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Males		3.771 (3.002 to 4.693)	3.175 (2.56 to 3.923)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [2500, 3000) g	Mortality	Females		3.244 (2.486 to 4.159)	3.228 (2.605 to 3.985)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Males		2.755 (2.274 to 3.309)	2.944 (2.44 to 3.548)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Females		4.662 (3.577 to 6.014)	2.398 (1.98 to 2.864)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Males		2.007 (1.759 to 2.293)	1.888 (1.613 to 2.224)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Females		1.925 (1.582 to 2.328)	1.972 (1.669 to 2.313)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Males		3.28 (2.596 to 4.133)	1.335 (1.171 to 1.532)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Females		3.521 (2.649 to 4.5)	1.559 (1.333 to 1.835)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Males		2.128 (1.833 to 2.466)	1.505 (1.299 to 1.76)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Females		2.142 (1.694 to 2.67)	1.661 (1.411 to 1.961)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Males		1.436 (1.245 to 1.65)	1.47 (1.199 to 1.8)																					
Hemolytic disease and other neonatal jaundice	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Females		1.326 (1.069 to 1.614)	1.465 (1.188 to 1.775)

Other neonatal disorders	Birth prevalence - [38, 40) wks, [2500, 3000) g	Mortality	Females		2.376 (1.91 to 2.886)	2.938 (2.434 to 3.503)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Males		3.774 (3.094 to 4.497)	2.466 (2.058 to 2.929)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [3000, 3500) g	Mortality	Females		3.73 (2.981 to 4.646)	2.715 (2.277 to 3.218)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Males		6.826 (5.212 to 9.045)	1.77 (1.491 to 2.082)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [4000, 4500) g	Mortality	Females		7.269 (5.144 to 9.821)	2.177 (1.786 to 2.607)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Males		4.544 (3.64 to 5.622)	2.057 (1.74 to 2.44)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [3500, 4000) g	Mortality	Females		4.662 (3.577 to 6.014)	2.398 (1.98 to 2.864)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Males		2.007 (1.759 to 2.293)	1.888 (1.613 to 2.224)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [3000, 3500) g	Mortality	Females		1.925 (1.582 to 2.328)	1.972 (1.669 to 2.313)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Males		3.28 (2.596 to 4.133)	1.335 (1.171 to 1.532)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [4000, 4500) g	Mortality	Females		3.521 (2.649 to 4.5)	1.559 (1.333 to 1.835)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Males		2.128 (1.833 to 2.466)	1.505 (1.299 to 1.76)																					
Other neonatal disorders	Birth prevalence - [37, 38) wks, [3500, 4000) g	Mortality	Females		2.142 (1.694 to 2.67)	1.661 (1.411 to 1.961)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Males		1.436 (1.245 to 1.65)	1.47 (1.199 to 1.8)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [3000, 3500) g	Mortality	Females		1.326 (1.069 to 1.614)	1.465 (1.188 to 1.775)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Males		1.33 (1.155 to 1.53)	1.559 (1.305 to 1.851)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [3000, 3500) g	Mortality	Females		1.224 (1.0 to 1.492)	1.564 (1.304 to 1.847)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Males		1.787 (1.453 to 2.182)	1.175 (1.005 to 1.371)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [4000, 4500) g	Mortality	Females		1.877 (1.467 to 2.388)	1.224 (1.022 to 1.465)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Males		1.785 (1.478 to 2.147)	1.173 (1.0 to 1.377)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [3500, 4000) g	Mortality	Females		1.892 (1.481 to 2.352)	1.23 (1.03 to 1.46)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Males		1.0 (1.0 to 1.0)	1.003 (1.0 to 1.046)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [3500, 4000) g	Mortality	Females		1.002 (1.0 to 1.013)	1.001 (1.0 to 1.006)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Males		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [4000, 4500) g	Mortality	Females		1.0 (1.0 to 1.0)	1.0 (1.0 to 1.0)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Males		117.172 (83.895 to 158.056)	27.726 (21.877 to 34.972)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [2000, 2500) g	Mortality	Females		121.682 (84.349 to 171.375)	33.983 (26.101 to 43.404)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Males		77.948 (54.687 to 105.047)	16.608 (12.653 to 21.188)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [2500, 3000) g	Mortality	Females		79.193 (54.099 to 112.236)	20.387 (15.089 to 26.434)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Males		42.199 (29.891 to 57.227)	10.082 (7.777 to 13.056)																					
Other neonatal disorders	Birth prevalence - [28, 30) wks, [3000, 3500) g	Mortality	Females		42.551 (28.25 to 63.209)	11.989 (9.084 to 15.544)																					

Appendix Table 6a. Relative risks used by age and sex for each outcome for all risk factors except for ambient air pollution alcohol, and smoking.

				Ages																					
Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All-age	0-6 days	7-27 days	28-364 days	1-4 years	5-9 years	10-14 years	15-19 years	20-24 years	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Other neonatal disorders	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Males		58.722 (42.419 to 78.873)	12.115 (9.518 to 15.521)																					
Other neonatal disorders	Birth prevalence - [30, 32) wks, [2500, 3000) g	Mortality	Females		59.522 (42.058 to 82.793)	15.364 (11.936 to 19.581)																					
Other neonatal disorders	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Males		45.67 (32.014 to 65.531)	8.381 (6.362 to 10.842)																					
Other neonatal disorders	Birth prevalence - [30, 32) wks, [3000, 3500) g	Mortality	Females		46.104 (30.243 to 66.207)	10.586 (8.041 to 13.513)																					
Other neonatal disorders	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Males		36.334 (21.558 to 54.813)	5.698 (4.293 to 7.349)																					
Other neonatal disorders	Birth prevalence - [30, 32) wks, [3500, 4000) g	Mortality	Females		37.931 (22.692 to 61.276)	6.892 (5.175 to 9.058)																					
Other neonatal disorders	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Males		34.016 (23.515 to 48.37)	6.577 (4.934 to 8.436)																					
Other neonatal disorders	Birth prevalence - [32, 34) wks, [3000, 3500) g	Mortality	Females		34.585 (22.909 to 49.754)	8.314 (6.362 to 10.789)																					
Other neonatal disorders	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Males		36.248 (23.158 to 54.67)	5.068 (3.761 to 6.741)																					
Other neonatal disorders	Birth prevalence - [32, 34) wks, [3500, 4000) g	Mortality	Females		38.098 (23.301 to 59.429)	6.476 (4.666 to 8.689)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Males		166.686 (118.487 to 222.581)	57.535 (45.999 to 71.742)																					
Other neonatal disorders	Birth prevalence - [36, 37) wks, [1000, 1500) g	Mortality	Females		169.725 (119.017 to 229.008)	63.564 (50.068 to 80.703)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Males		174.066 (125.125 to 232.507)	57.966 (44.393 to 73.241)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [1000, 1500) g	Mortality	Females		171.557 (121.585 to 237.047)	65.208 (48.821 to 84.308)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Males		67.302 (49.547 to 89.055)	25.206 (20.365 to 31.168)																					
Other neonatal disorders	Birth prevalence - [38, 40) wks, [1500, 2000) g	Mortality	Females		62.19 (45.884 to 83.445)	28.05 (22.625 to 35.139)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Males		76.673 (56.177 to 102.468)	25.785 (19.387 to 34.168)																					
Other neonatal disorders	Birth prevalence - [40, 42) wks, [1500, 2000) g	Mortality	Females		70.411 (49.221 to 97.952)	29.113 (21.355 to 38.272)																					
Sudden infant death syndrome	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Males		1564.792 (1056.542 to 2116.967)	618.595 (458.842 to 812.921)																					
Sudden infant death syndrome	Birth prevalence - [0, 24) wks, [0, 500) g	Mortality	Females		1600.122 (1050.664 to 2111.877)	713.571 (526.178 to 921.018)																					
Sudden infant death syndrome	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Males		1155.815 (825.412 to 1506.837)	457.5 (352.552 to 573.483)																					
Sudden infant death syndrome	Birth prevalence - [0, 24) wks, [500, 1000) g	Mortality	Females		1169.123 (802.003 to 1617.979)	515.406 (396.713 to 641.541)																					
Sudden infant death syndrome	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Males		955.583 (723.748 to 1244.265)	443.357 (363.03 to 534.695)																					
Sudden infant death syndrome	Birth prevalence - [24, 26) wks, [500, 1000) g	Mortality	Females		947.143 (762.662 to 1237.093)	487.549 (387.307 to 603.498)																					
Sudden infant death syndrome	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Males		497.817 (377.617 to 648.547)	330.886 (261.438 to 401.709)																					
Sudden infant death syndrome	Birth prevalence - [26, 28) wks, [500, 1000) g	Mortality	Females		483.682 (354.946 to 629.517)	344.618 (274.427 to 419.864)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Males		236.614 (163.821 to 324.502)	149.995 (117.866 to 188.368)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [500, 1000) g	Mortality	Females		229.197 (157.606 to 317.194)	152.117 (120.779 to 190.583)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Males		297.029 (214.953 to 396.586)	216.995 (173.321 to 271.466)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [500, 1000) g	Mortality	Females		281.056 (198.176 to 386.635)	219.884 (174.264 to 272.704)																					
Sudden infant death syndrome	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Males		267.91 (210.177 to 332.92)	164.167 (132.898 to 200.569)																					
Sudden infant death syndrome	Birth prevalence - [26, 28) wks, [1000, 1500) g	Mortality	Females		266.509 (197.461 to 346.932)	174.222 (137.431 to 217.349)																					
Sudden infant death syndrome	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Males		142.056 (98.086 to 197.774)	52.86 (42.914 to 64.617)																					
Sudden infant death syndrome	Birth prevalence - [34, 36) wks, [1000, 1500) g	Mortality	Females		141.899 (95.864 to 197.656)	57.421 (46.452 to 71.339)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Males		127.966 (97.178 to 167.026)	50.018 (40.539 to 61.919)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [1500, 2000) g	Mortality	Females		130.924 (96.513 to 172.188)	57.275 (46.36 to 70.038)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Males		158.563 (120.99 to 204.947)	103.32 (83.486 to 127.144)																					
Sudden infant death syndrome	Birth prevalence - [28, 30) wks, [1000, 1500) g	Mortality	Females		153.905 (112.327 to 200.786)	107.529 (86.954 to 131.78)																					
Sudden infant death syndrome	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Males		117.142 (81.354 to 161.101)	53.185 (43.049 to 66.274)																					
Sudden infant death syndrome	Birth prevalence - [32, 34) wks, [1000, 1500) g	Mortality	Females		115.171 (79.363 to 159.206)	56.034 (45.982 to 68.36)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Males		119.308 (87.769 to 160.885)	67.163 (54.863 to 82.638)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [1000, 1500) g	Mortality	Females		115.448 (84.272 to 156.425)	69.14 (55.873 to 85.012)																					
Sudden infant death syndrome	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Males		62.972 (46.159 to 83.484)	24.148 (20.066 to 29.406)																					
Sudden infant death syndrome	Birth prevalence - [37, 38) wks, [1500, 2000) g	Mortality	Females		59.988 (43.974 to 79.053)	26.719 (21.746 to 32.816)																					
Sudden infant death syndrome	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Males		60.218 (43.669 to 82.48)	23.031 (18.793 to 28.483)																					
Sudden infant death syndrome	Birth prevalence - [36, 37) wks, [1500, 2000) g	Mortality	Females		58.527 (42.172 to 80.557)	25.143 (20.331 to 30.566)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Males		67.971 (50.354 to 88.935)	18.03 (14.621 to 22.103)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [2000, 2500) g	Mortality	Females		69.383 (49.108 to 94.583)	22.069 (17.836 to 27.163)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Males		77.369 (59.702 to 99.232)	31.079 (25.786 to 36.724)																					
Sudden infant death syndrome	Birth prevalence - [30, 32) wks, [1500, 2000) g	Mortality	Females		76.134 (56.885 to 100.996)	34.756 (28.764 to 41.849)																					
Sudden infant death syndrome	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Males		55.555 (39.553 to 75.104)	21.346 (17.677 to 26.143)																					
Sudden infant death syndrome	Birth prevalence - [34, 36) wks, [1500, 2000) g	Mortality	Females		54.335 (38.617 to 75.24)	23.046 (18.743 to 28.287)

* Occupational noise relative risk values are for sequela

** Shifts are reported for diet high in sodium as the estimation is based on mediation through high systolic blood pressure.

Risk-outcome pairs with 100% attribution

Alcohol use
Liver cancer due to alcohol use
Cirrhosis due to alcohol use
Alcohol use disorders
Childhood underweight
Protein-energy malnutrition
Childhood wasting
Protein-energy malnutrition
Drug use
Opioid use disorders
Cocaine use disorders
Amphetamine use disorders
Cannabis use disorders
Other drug use disorders

High fasting plasma glucose
Diabetes mellitus
Chronic kidney disease due to diabetes mellitus
High systolic blood pressure
Hypertensive heart disease
Chronic kidney disease due to hypertension
Iron deficiency
Iron-deficiency anaemia
Low glomerular filtration rate
Chronic kidney disease due to diabetes mellitus
Chronic kidney disease due to hypertension
Chronic kidney disease due to glomerulonephritis
Chronic kidney disease due to other causes

Occupational particulate matter, gases, and fumes
Coal workers pneumoconiosis
Unsafe sex
Syphilis
Chlamydial infection
Gonococcal infection
Trichomoniasis
Genital herpes
Other sexually transmitted diseases
Cervical cancer
Sexually transmitted diseases excluding HIV
Vitamin A deficiency
Vitamin A deficiency

Appendix Table 6b. Relative risks used by age and sex for each outcome for the particulate matter integrated exposure response curve.

Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	Age															
				All ages	25-29 years	30-34 years	35-39 years	40-44 years	45-49 years	50-54 years	55-59 years	60-64 years	65-69 years	70-74 years	75-79 years	80-84 years	85-89 years	90-94 years	95+ years
Ambient particulate matter pollution (PM2.5)																			
Lower respiratory infections	600 µg/m³	Both	Both	2.38 (1.968 to 2.776)															
Lower respiratory infections	500 µg/m³	Both	Both	2.347 (1.936 to 2.735)															
Lower respiratory infections	400 µg/m³	Both	Both	2.297 (1.883 to 2.687)															
Lower respiratory infections	300 µg/m³	Both	Both	2.213 (1.809 to 2.615)															
Lower respiratory infections	200 µg/m³	Both	Both	2.062 (1.702 to 2.44)															
Lower respiratory infections	150 µg/m³	Both	Both	1.938 (1.629 to 2.281)															
Lower respiratory infections	135 µg/m³	Both	Both	1.891 (1.6 to 2.209)															
Lower respiratory infections	120 µg/m³	Both	Both	1.838 (1.571 to 2.129)															
Lower respiratory infections	105 µg/m³	Both	Both	1.778 (1.54 to 2.05)															
Lower respiratory infections	90 µg/m³	Both	Both	1.711 (1.505 to 1.945)															
Lower respiratory infections	75 µg/m³	Both	Both	1.634 (1.455 to 1.827)															
Lower respiratory infections	60 µg/m³	Both	Both	1.546 (1.4 to 1.711)															
Lower respiratory infections	45 µg/m³	Both	Both	1.443 (1.323 to 1.576)															
Lower respiratory infections	30 µg/m³	Both	Both	1.322 (1.225 to 1.428)															
Lower respiratory infections	25 µg/m³	Both	Both	1.276 (1.184 to 1.379)															
Lower respiratory infections	20 µg/m³	Both	Both	1.226 (1.14 to 1.335)															
Lower respiratory infections	15 µg/m³	Both	Both	1.171 (1.093 to 1.282)															
Lower respiratory infections	10 µg/m³	Both	Both	1.108 (1.046 to 1.219)															
Lower respiratory infections	5 µg/m³	Both	Both	1.025 (1.0 to 1.119)															
Lower respiratory infections	0 µg/m³	Both	Both	1.0 (1.0 to 1.0)															
Tracheal, bronchus, and lung cancer	600 µg/m³	Both	Both	2.541 (2.222 to 2.868)															
Tracheal, bronchus, and lung cancer	500 µg/m³	Both	Both	2.369 (2.074 to 2.675)															
Tracheal, bronchus, and lung cancer	400 µg/m³	Both	Both	2.185 (1.919 to 2.469)															
Tracheal, bronchus, and lung cancer	300 µg/m³	Both	Both	1.982 (1.748 to 2.229)															
Tracheal, bronchus, and lung cancer	200 µg/m³	Both	Both	1.753 (1.56 to 1.958)															
Tracheal, bronchus, and lung cancer	150 µg/m³	Both	Both	1.622 (1.454 to 1.802)															
Tracheal, bronchus, and lung cancer	135 µg/m³	Both	Both	1.58 (1.421 to 1.754)															
Tracheal, bronchus, and lung cancer	120 µg/m³	Both	Both	1.536 (1.385 to 1.701)															
Tracheal, bronchus, and lung cancer	105 µg/m³	Both	Both	1.49 (1.348 to 1.648)

Ischaemic stroke	60 g/day	Both	Male	1.312 (1.167 to 1.471)
Ischaemic stroke	48 g/day	Both	Male	1.159 (0.98 to 1.353)
Ischaemic stroke	36 g/day	Both	Male	1.057 (0.931 to 1.192)
Ischaemic stroke	24 g/day	Both	Male	0.97 (0.862 to 1.088)
Ischaemic stroke	12 g/day	Both	Male	0.938 (0.83 to 1.054)
Ischaemic stroke	0 g/day	Both	Male	1.0 (1.0 to 1.0)
Ischaemic stroke	72 g/day	Both	Female	1.43 (1.147 to 1.771)
Ischaemic stroke	60 g/day	Both	Female	1.3 (1.121 to 1.496)

Appendix Table 6c. Relative risks used by age and sex for each outcome for alcohol use globally.

Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All ages
Alcohol use				
Ischaemic stroke	48 g/day	Both	Female	1.145 (0.946 to 1.359)
Ischaemic stroke	36 g/day	Both	Female	0.985 (0.834 to 1.149)
Ischaemic stroke	24 g/day	Both	Female	0.85 (0.726 to 0.985)
Ischaemic stroke	12 g/day	Both	Female	0.824 (0.718 to 0.939)
Ischaemic stroke	0 g/day	Both	Female	1.0 (1.0 to 1.0)
Intracerebral hemorrhage	72 g/day	Both	Male	1.971 (1.663 to 2.316)
Intracerebral hemorrhage	60 g/day	Both	Male	1.705 (1.45 to 1.991)
Intracerebral hemorrhage	48 g/day	Both	Male	1.458 (1.182 to 1.768)
Intracerebral hemorrhage	36 g/day	Both	Male	1.31 (1.105 to 1.539)
Intracerebral hemorrhage	24 g/day	Both	Male	1.162 (0.973 to 1.385)
Intracerebral hemorrhage	12 g/day	Both	Male	1.068 (0.945 to 1.214)
Intracerebral hemorrhage	0 g/day	Both	Male	1.0 (1.0 to 1.0)
Intracerebral hemorrhage	72 g/day	Both	Female	2.276 (1.701 to 2.934)
Intracerebral hemorrhage	60 g/day	Both	Female	1.964 (1.536 to 2.464)
Intracerebral hemorrhage	48 g/day	Both	Female	1.614 (1.245 to 2.048)
Intracerebral hemorrhage	36 g/day	Both	Female	1.337 (1.065 to 1.664)
Intracerebral hemorrhage	24 g/day	Both	Female	1.11 (0.884 to 1.367)
Intracerebral hemorrhage	12 g/day	Both	Female	1.031 (0.897 to 1.18)
Intracerebral hemorrhage	0 g/day	Both	Female	1.0 (1.0 to 1.0)
Hypertensive heart disease	72 g/day	Both	Both	1.86 (1.445 to 2.358)
Hypertensive heart disease	60 g/day	Both	Both	1.705 (1.297 to 2.175)
Hypertensive heart disease	48 g/day	Both	Both	1.614 (1.25 to 2.049)
Hypertensive heart disease	36 g/day	Both	Both	1.479 (1.232 to 1.759)
Hypertensive heart disease	24 g/day	Both	Both	1.315 (1.136 to 1.526)
Hypertensive heart disease	12 g/day	Both	Both	1.046 (0.913 to 1.198)
Hypertensive heart disease	0 g/day	Both	Both	1.0 (1.0 to 1.0)
Atrial fibrillation and flutter	72 g/day	Both	Both	1.535 (1.348 to 1.728)
Atrial fibrillation and flutter	60 g/day	Both	Both	1.411 (1.26 to 1.569)
Atrial fibrillation and flutter	48 g/day	Both	Both	1.312 (1.218 to 1.407)
Atrial fibrillation and flutter	36 g/day	Both	Both	1.214 (1.145 to 1.29)
Atrial fibrillation and flutter	24 g/day	Both	Both	1.131 (1.067 to 1.204)

Appendix Table 6c. Relative risks used by age and sex for each outcome for alcohol use globally.

Risk - Outcome	Category / Units	Morbidity / Mortality	Sex	All ages
Alcohol use				
Atrial fibrillation and flutter	12 g/day	Both	Both	1.066 (1.034 to 1.102)
Atrial fibrillation and flutter	0 g/day	Both	Both	1.0 (1.0 to 1.0)
Cirrhosis and other chronic liver diseases due to alcohol use	72 g/day	Both	Both	9.427 (6.131 to 13.804)
Cirrhosis and other chronic liver diseases due to alcohol use	60 g/day	Both	Both	6.274 (3.958 to 9.319)
Cirrhosis and other chronic liver diseases due to alcohol use	48 g/day	Both	Both	4.673 (3.25 to 6.717)
Cirrhosis and other chronic liver diseases due to alcohol use	36 g/day	Both	Both	3.274 (2.309 to 4.485)
Cirrhosis and other chronic liver diseases due to alcohol use	24 g/day	Both	Both	2.055 (1.521 to 2.688)
Cirrhosis and other chronic liver diseases due to alcohol use	12 g/day	Both	Both	1.243 (0.943 to 1.611)
Cirrhosis and other chronic liver diseases due to alcohol use	0 g/day	Both	Both	1.0 (1.0 to 1.0)
Pancreatitis	72 g/day	Both	Both	3.298 (2.473 to 4.458)
Pancreatitis	60 g/day	Both	Both	2.217 (1.415 to 3.389)
Pancreatitis	48 g/day	Both	Both	1.717 (1.199 to 2.477)
Pancreatitis	36 g/day	Both	Both	1.471 (1.062 to 2.021)
Pancreatitis	24 g/day	Both	Both	1.228 (0.874 to 1.67)

Appendix Table 8. Mediation factors

For IHD, stroke, and diabetes we pooled all available cohorts and estimated relative risks with and without adjustment across all combinations of metabolic risk factors. We then computed the excess attenuated risk for each mediation-risk-cause set.

Risk Factor	Mediator	Cause	Mediation Factor
Lead exposure in bone	High systolic blood pressure	Rheumatic heart disease	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Ischaemic heart disease	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Ischaemic stroke	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Intracerebral hemorrhage	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Subarachnoid hemorrhage	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Hypertensive heart disease	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Other cardiomyopathy	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Atrial fibrillation and flutter	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Aortic aneurysm	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Peripheral vascular disease	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Other cardiovascular and circulatory diseases	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Chronic kidney disease due to hypertension	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
Lead exposure in bone	High systolic blood pressure	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
Lead exposure in bone	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
Lead exposure in bone	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
Lead exposure in bone	Impaired kidney function	Chronic kidney disease due to hypertension	1 (1 to 1)
Lead exposure in bone	Impaired kidney function	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
Lead exposure in bone	Impaired kidney function	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
Smoking	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
Smoking	Low bone mineral density	Pedestrian road injuries	1 (1 to 1)
Smoking	Low bone mineral density	Cyclist road injuries	1 (1 to 1)
Smoking	Low bone mineral density	Motor vehicle road injuries	1 (1 to 1)
Smoking	Low bone mineral density	Other road injuries	1 (1 to 1)
Smoking	Low bone mineral density	Other transport injuries	1 (1 to 1)
Smoking	Low bone mineral density	Falls	1 (1 to 1)
Smoking	Low bone mineral density	Other exposure to mechanical forces	1 (1 to 1)
Smoking	Low bone mineral density	Non-venomous animal contact	1 (1 to 1)
Smoking	Low bone mineral density	Assault by other means	1 (1 to 1)
Diet low in fruits	High fasting plasma glucose	Ischaemic stroke	0.05 (0.04 to 0.06)

Appendix Table 8. Mediation factors

For IHD, stroke, and diabetes we pooled all available cohorts and estimated relative risks with and without adjustment across all combinations of metabolic risk factors. We then computed the excess attenuated risk for each mediation–risk-cause set.

Risk Factor	Mediator	Cause	Mediation Factor
Diet low in fruits	High fasting plasma glucose	Diabetes mellitus type 2	0.99 (0.99 to 0.99)
Diet low in fruits	High LDL cholesterol	Ischaemic heart disease	0.06 (0.05 to 0.08)
Diet low in fruits	High LDL cholesterol	Ischaemic stroke	0.05 (0.04 to 0.06)
Diet low in fruits	High systolic blood pressure	Ischaemic heart disease	0.06 (0.05 to 0.08)
Diet low in fruits	High systolic blood pressure	Ischaemic stroke	0.05 (0.04 to 0.06)
Diet low in fruits	High systolic blood pressure	Intracerebral hemorrhage	0.02 (0.02 to 0.03)
Diet low in fruits	High systolic blood pressure	Subarachnoid hemorrhage	0.02 (0.02 to 0.03)
Diet low in vegetables	High fasting plasma glucose	Ischaemic heart disease	0.06 (0.01 to 0.2)
Diet low in vegetables	High fasting plasma glucose	Ischaemic stroke	0.08 (0.04 to 0.16)
Diet low in vegetables	High fasting plasma glucose	Intracerebral hemorrhage	0.08 (0.04 to 0.16)
Diet low in vegetables	High fasting plasma glucose	Subarachnoid hemorrhage	0.08 (0.04 to 0.16)
Diet low in vegetables	High LDL cholesterol	Ischaemic heart disease	0.04 (0.03 to 0.05)
Diet low in vegetables	High LDL cholesterol	Ischaemic stroke	0.09 (0.04 to 0.16)
Diet low in vegetables	High systolic blood pressure	Ischaemic heart disease	0.04 (0.03 to 0.05)
Diet low in vegetables	High systolic blood pressure	Ischaemic stroke	0.03 (0.02 to 0.04)
Diet low in vegetables	High systolic blood pressure	Intracerebral hemorrhage	0.04 (0.02 to 0.05)
Diet low in vegetables	High systolic blood pressure	Subarachnoid hemorrhage	0.04 (0.02 to 0.05)
Diet low in whole grains	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
Diet low in whole grains	High LDL cholesterol	Ischaemic heart disease	0.39 (0.17 to 0.54)
Diet low in whole grains	High LDL cholesterol	Ischaemic stroke	0.16 (0.05 to 0.37)
Diet low in nuts and seeds	High fasting plasma glucose	Ischaemic heart disease	0.03 (0.02 to 0.06)
Diet low in nuts and seeds	High fasting plasma glucose	Diabetes mellitus type 2	0.99 (0.99 to 0.99)
Diet low in nuts and seeds	High LDL cholesterol	Ischaemic heart disease	0.28 (0.01 to 1.62)
Diet low in nuts and seeds	High systolic blood pressure	Ischaemic heart disease	0.34 (0.24 to 0.47)
Diet low in milk	Diet low in calcium	Colon and rectum cancer	1 (1 to 1)
Diet high in red meat	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
Diet high in processed meat	High fasting plasma glucose	Ischaemic heart disease	0.01 (0.01 to 0.02)
Diet high in processed meat	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
Diet high in sugar-sweetened beverages	High fasting plasma glucose	Ischaemic heart disease	0.15 (0.1 to 0.2)
Diet high in sugar-sweetened beverages	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
Diet high in sugar-sweetened beverages	High LDL cholesterol	Ischaemic heart disease	0.1 (0.05 to 0.15)
Diet high in sugar-sweetened beverages	High systolic blood pressure	Ischaemic heart disease	0.31 (0.28 to 0.34)

Appendix Table 8. Mediation factors

For IHD, stroke, and diabetes we pooled all available cohorts and estimated relative risks with and without adjustment across all combinations of metabolic risk factors. We then computed the excess attenuated risk for each mediation–risk-cause set.

Risk Factor	Mediator	Cause	Mediation Factor
Diet high in sugar-sweetened beverages	High body-mass index	Ischaemic heart disease	1 (1 to 1)
Diet high in sugar-sweetened beverages	High body-mass index	Diabetes mellitus type 2	1 (1 to 1)
Diet low in fibre	Diet low in fruits	Ischaemic heart disease	1 (1 to 1)
Diet low in fibre	Diet low in vegetables	Ischaemic heart disease	1 (1 to 1)
Diet low in fibre	Diet low in whole grains	Ischaemic heart disease	1 (1 to 1)
Diet low in seafood omega-3 fatty acids	High systolic blood pressure	Ischaemic heart disease	0.01 (0 to 0.02)
Diet low in polyunsaturated fatty acids	High fasting plasma glucose	Ischaemic heart disease	0.57 (0.39 to 0.77)
Diet low in polyunsaturated fatty acids	High systolic blood pressure	Ischaemic heart disease	0.72 (0.57 to 0.89)
Diet high in trans fatty acids	High LDL cholesterol	Ischaemic heart disease	0.15 (0.02 to 0.24)
Diet high in trans fatty acids	High systolic blood pressure	Ischaemic heart disease	0.15 (0.02 to 0.24)
Diet high in sodium	High systolic blood pressure	Rheumatic heart disease	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Ischaemic heart disease	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Ischaemic stroke	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Intracerebral hemorrhage	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Subarachnoid hemorrhage	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Hypertensive heart disease	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Other cardiomyopathy	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Atrial fibrillation and flutter	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Aortic aneurysm	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Peripheral vascular disease	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Other cardiovascular and circulatory diseases	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Chronic kidney disease due to hypertension	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
Diet high in sodium	High systolic blood pressure	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
Diet high in sodium	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
Diet high in sodium	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
Diet high in sodium	Impaired kidney function	Chronic kidney disease due to hypertension	1 (1 to 1)
Diet high in sodium	Impaired kidney function	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
Diet high in sodium	Impaired kidney function	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
Childhood sexual abuse	Alcohol use	Alcohol use disorders	1 (1 to 1)

Appendix Table 8. Mediation factors

For IHD, stroke, and diabetes we pooled all available cohorts and estimated relative risks with and without adjustment across all combinations of metabolic risk factors. We then computed the excess attenuated risk for each mediation-risk-cause set.

Risk Factor	Mediator	Cause	Mediation Factor
Low physical activity	High fasting plasma glucose	Ischaemic heart disease	0.14 (0.11 to 0.18)
Low physical activity	High fasting plasma glucose	Ischaemic stroke	0.08 (0.03 to 0.14)
Low physical activity	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
High fasting plasma glucose	High LDL cholesterol	Ischaemic heart disease	0.04 (0.02 to 0.05)
High fasting plasma glucose	High LDL cholesterol	Ischaemic stroke	0.04 (0.03 to 0.06)
High fasting plasma glucose	High systolic blood pressure	Ischaemic heart disease	0.1 (0.08 to 0.11)
High fasting plasma glucose	High systolic blood pressure	Ischaemic stroke	0.15 (0.14 to 0.17)
High fasting plasma glucose	High systolic blood pressure	Intracerebral hemorrhage	0.15 (0.14 to 0.17)
High fasting plasma glucose	High systolic blood pressure	Subarachnoid hemorrhage	0.15 (0.14 to 0.17)
High fasting plasma glucose	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
High fasting plasma glucose	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
High fasting plasma glucose	Impaired kidney function	Chronic kidney disease due to hypertension	1 (1 to 1)
High fasting plasma glucose	Impaired kidney function	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
High fasting plasma glucose	Impaired kidney function	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
High LDL cholesterol	High systolic blood pressure	Ischaemic heart disease	0.09 (0.07 to 0.11)
High LDL cholesterol	High systolic blood pressure	Ischaemic stroke	0.16 (0.14 to 0.18)
High systolic blood pressure	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 1	1 (1 to 1)
High systolic blood pressure	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
High systolic blood pressure	Impaired kidney function	Chronic kidney disease due to hypertension	1 (1 to 1)
High systolic blood pressure	Impaired kidney function	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
High systolic blood pressure	Impaired kidney function	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
High body-mass index	High fasting plasma glucose	Ischaemic heart disease	0.15 (0.1 to 0.2)
High body-mass index	High fasting plasma glucose	Ischaemic stroke	0.22 (0.12 to 0.31)
High body-mass index	High fasting plasma glucose	Intracerebral hemorrhage	0.22 (0.13 to 0.32)
High body-mass index	High fasting plasma glucose	Subarachnoid hemorrhage	0.22 (0.13 to 0.32)
High body-mass index	High fasting plasma glucose	Diabetes mellitus type 2	1 (1 to 1)
High body-mass index	High LDL cholesterol	Ischaemic heart disease	0.1 (0.05 to 0.15)
High body-mass index	High LDL cholesterol	Ischaemic stroke	0.03 (0 to 0.08)
High body-mass index	High systolic blood pressure	Ischaemic heart disease	0.31 (0.28 to 0.34)
High body-mass index	High systolic blood pressure	Ischaemic stroke	0.65 (0.57 to 0.72)
High body-mass index	High systolic blood pressure	Intracerebral hemorrhage	0.65 (0.58 to 0.73)
High body-mass index	High systolic blood pressure	Subarachnoid hemorrhage	0.65 (0.58 to 0.73)

Appendix Table 8. Mediation factors

For IHD, stroke, and diabetes we pooled all available cohorts and estimated relative risks with and without adjustment across all combinations of metabolic risk factors. We then computed the excess attenuated risk for each mediation-risk-cause set.

Risk Factor	Mediator	Cause	Mediation Factor
High body-mass index	High systolic blood pressure	Hypertensive heart disease	1 (1 to 1)
High body-mass index	High systolic blood pressure	Atrial fibrillation and flutter	0.31 (0.28 to 0.34)
High body-mass index	Impaired kidney function	Chronic kidney disease due to diabetes mellitus type 2	1 (1 to 1)
High body-mass index	Impaired kidney function	Chronic kidney disease due to hypertension	1 (1 to 1)
High body-mass index	Impaired kidney function	Chronic kidney disease due to glomerulonephritis	1 (1 to 1)
High body-mass index	Impaired kidney function	Chronic kidney disease due to other and unspecified causes	1 (1 to 1)
