24 **Abstract**

25 The verification of the geographical origin of extra virgin (EVOO) and virgin olive oil (VOO) is crucial to protect
26 consumers from misleading information. Despite the large number of studies performed, specific markers are
27 still not available. The present study aims to evaluate sesquiterpene hydrocarbons (SHs) as markers of EVOO
28 geographical origin and to compare the discrimination efficiency of targeted profiling and fingerprinting
29 approaches. A prospective study was carried out on 82 EVOOs from seven countries, analyzed by Headspace
30 Solid Phase Microextraction-Gas Chromatography-Mass Spectrometry (HS-SPME-GC-MS). Classification models
31 were developed by Partial Least Square-Discriminant Analysis (PLS-DA) and internally validated (leave 10%-out
32 cross-validation). The % of correct classification was higher for the fingerprinting (100%) than for the profiling
33 approach (45.5-100%). These results confirm the suitability of SHs as EVOO geographical markers and establish
34 the fingerprinting as the most efficient approach for the treatment of SH analytical data with this purpose up to
35 date.

36 **Keywords**

37 Fingerprinting; Geographical origin; Virgin Olive Oil; Sesquiterpene; Food authentication.

38 **1. Introduction**

39 As reported by EU Parliament ([Parliament Resolution EU No 2013/2091 \(INI\)](#)), the cases of food fraud reduce the
40 confidence of consumers in the food chain, compromising its global image and causing a negative influence in
41 the food sector. [EU Regulation No 29/2012](#) states as mandatory the country of origin in labeling extra virgin olive
42 oil (EVOO) and virgin olive oil (VOO) to inform the consumer regarding their geographical origin. The geographical
43 origin reported in the label refers to i) a single EU Member State or third country, ii) oil blends of European Union
44 or non-European Union origin, or iii) certain protected designations of origin or protected geographical
45 indications according to EU Regulation ([Regulation \(EU\) No 1151/2012](#)). The verification of conformity of the
46 label-declared geographical origin of EVOO and VOO plays a key role, not only to protect consumers from
47 misleading information and restore their confidence in the product, but also to detect and prevent fraudulent
48 practices and increase the competitiveness of the sector. A large number of studies have been performed trying
49 to face up the EVOO geographical authentication. They have been based on several chemical compounds such
50 as triacylglycerols, fatty acids, phenolic compounds, pigments, sterols and volatile compounds, by applying
51 different analytical techniques as well as chemometric approaches ([Bajoub, Bendini, Fernández-Gutiérrez &](#)
52 [Carrasco-Pancorbo, 2018](#); [Conte et al., 2019](#)). However, it is known that the levels of some of these analytes
53 change along EVOO shelf life (i.e. phenols and pigments) and others are related to olive oil quality/purity (i.e.
54 volatile compounds), meaning that they can be affected by storage and processing factors ([García-González &](#)
55 [Aparicio, 2010](#)). Other studies focused on the olive oil chemical fingerprint by stable Isotope Ratio Mass
56 Spectrometry and Nuclear Magnetic Resonance ([Alonso-Salces et al., 2015](#); [Camin et al., 2016](#)). Even though their
57 results were promising by combining data from both analyses, they require smart instrumentation that is not
58 often affordable for common control laboratories. For these reasons, we can state that there is room still for
59 improvement in the development of EVOO and VOO geographical markers.

60 To develop efficient tools for the geographical authentication of EVOO and VOO, it is necessary to identify the
61 most robust markers and analytical approaches. To be reliable, geographical markers of food products should
62 depend mainly climatic and agronomic factors linked to a specific area, while keeping the influence of other

63 factors to a minimal degree (Vichi, Tres, Quintanilla-Casas, Bustamante & Guardiola, 2018). Additionally, the
64 determination of such markers for routine analysis should imply low cost, short times and automatable
65 procedures.

66 Recent studies reveal that sesquiterpene hydrocarbons (SHs) might act as valid markers to address the genetic
67 and geographical origin of EVOO and VOO (Bortolomeazzi, Berno, Pizzale & Conte, 2001; Zunin, Boggia, Salvadeo
68 & Evangelisti, 2005; Vichi, Guadayol, Caixach, Lopez-Tamames & Buxaderas, 2006; Vichi, Lazzez, Grati-Kamoun,
69 Lopez-Tamames & Buxaderas, 2010; Damascelli & Palmisano, 2013). SHs are semi-volatile plant metabolites
70 comprising an extremely wide number of compounds in nature. In EVOO and VOO, SH composition is highly
71 dependent on the olive trees' cultivar and growing area, and scarcely influenced by other factors such as oil
72 extraction conditions and storage (Vichi et al., 2018). The effect of agronomic and pedoclimatic conditions on
73 olive oil SHs has been proven by the fact that significant differences in the SH composition have been found
74 between samples from the same cultivar produced in different geographical areas (Ben Temime, Campeol, Cioni,
75 Daoud & Zarrouk, 2006; Youssef et al., 2011; Vichi et al., 2015) and also between EVOOs from different cultivars
76 grown in the same parcel did (Vichi et al., 2010). However, the suitability of SHs as geographical markers in a
77 realistic scenario should be tested with olive oils from different geographical areas under the usual production
78 practices, implying the use of monovarietal oils from typical olive cultivars as well as their usual market blends,
79 as addressed by some studies (Zunin et al., 2005; Damascelli & Palmisano, 2013).

80 In the last years, the analysis of SHs has evolved from time-consuming methods (Bortolomeazzi et al., 2001) to
81 simpler methods based on the analysis of the volatile fraction such as solid phase microextraction (SPME) (Vichi
82 et al., 2006), allowing further studies of these compounds in EVOOs and VOOs and considering their use as
83 possible authenticity markers.

84 Concerning the analytical approach, the traditional way to assess these semi-volatile compounds is based on a
85 target-type analysis to identify and determine the SH profile of samples. This approach involves a peak
86 identification step, which presents some difficulties because the mass spectra of these analytes contain the same

87 specific ions in different proportions, which causes that many SHs have not been identified yet. Consequently,
88 under a targeted profiling approach, as defined by Ballin and Laursen (2019), part of the information is ignored.
89 Nowadays, the emerging strategy in food authentication consists in finding specific patterns in highly
90 dimensional analytical data, known as fingerprints, which might be based directly in raw analytical signals such
91 as a chromatogram (Berrueta, Alonso-Salces & Heberger, 2007; Bosque-Sendra, Cuadros-Rodriguez, Ruiz-
92 Samblas & de la Mata, 2012; Melucci et al., 2016; Ballin & Laursen, 2019). When these distinctive patterns are
93 specific to a given food category (such as a particular geographical origin) and can be used to verify its
94 authenticity. Under the fingerprinting approach, since peak identification and quantitation are not necessary,
95 some of the drawbacks related with the targeted profiling approach mentioned above are overcome. Besides,
96 since the full analytical data is used, more information is considered and misclassifications are revealed easier.
97 With the aim to evaluate the suitability of SHs as geographical markers for EVOO and VOO under real production
98 conditions we carried out a prospective study on EVOOs from seven different geographical origins, comprising
99 monovarietal oils as well as market blends of oils from various cultivars typically produced in these origins. The
100 SHs were determined by HS-SPME and gas chromatography-mass spectrometry (GC-MS) and data was evaluated
101 under targeted (profiling) and non-targeted (fingerprinting) analytical approaches with the aim to compare their
102 discrimination-efficiency in the verification of the geographical origin.

103

104 **2. Material and Methods**

105 **2.1. Sampling**

106 A total of 82 authentic and traceable samples, declared as EVOO by the suppliers, were obtained in the
107 framework of OLEUM project (EC H2020 Programme 2014-2020) from seven different EU and non-EU countries:
108 Croatia (HRV) (n=11); Slovenia (SVN) (n=8); Spain (ESP) (n=17); Italy (ITA) (n=15); Greece (GRC) (n=6); Morocco
109 (MAR) (n=15) and Turkey (TUR) (n=10). With the aim of reflecting the real production scenario, EVOO samples in
110 this prospective study were obtained under usual production practices for commercial purposes, and thus

111 consisted of both monovarietal oils as well as market blends of olive cultivars typical of each geographical origin
112 **(Supplementary material, Table S1).**

113 **2.2. Headspace-Solid Phase Microextraction (HS-SPME)**

114 SHs present in EVOO were analyzed using a Triplus autosampler (Thermo Fischer Scientific, Bremen, Germany)
115 at the conditions reported by Vichi et al. (2006). Shortly, 2 g of oil was weighed into a 10 mL vial fitted with a
116 silicone septum and kept at 70 °C under agitation. After 10 min of sample conditioning, a
117 divinylbenzene/carboxen/polydimethylsiloxane (DVB/CAR/PDMS) fiber (2 cm length, 50/30 µm film thickness)
118 was exposed during 60 min to the sample headspace and then desorbed for 10 min in the GC injection port (260
119 °C). The thermal stability of SHs at these SPME conditions was previously verified (Vichi et al., 2006). During the
120 desorption step, the injector was maintained in split-less mode during 5 min. Oil samples were previously spiked
121 with a standard solution of indene to a final concentration of 10 µg/kg.

122 **2.3. Gas Chromatography-Mass Spectrometry (GC-MS)**

123 Separation and detection of volatile compounds was performed by GC coupled to an ion trap mass selective
124 spectrometry using a ThermoFinnigan Trace GC equipped with an ITQ MS (Thermo Fisher Scientific, Waltham,
125 MA) using helium as carrier gas at a constant flow of 1.3 mL min⁻¹. Analytes were separated on a Supelcowax-10
126 (Supelco, Bellefonte, PA) 60 m x 0.25 mm i.d., 0.25 µm film thickness. Column temperature was held at 40 °C for
127 3 min, increased to 75 at 4 °C min⁻¹, then to 200 at 8 °C min⁻¹ and to 260 °C at 15 °C min⁻¹, holding the last
128 temperature for 2 min. The temperatures of the ion source and the transfer line were 200 and 275 °C,
129 respectively. Mass spectra were recorded with a scan event time of 0.37 s; electron energy was 70 eV. Acquisition
130 in the complete scanning mode (SCAN) was in the range m/z 40-300, to allow the identification of compounds in
131 EVOO samples.

132 **2.3. Data processing**

133 **2.3.1. Profiling approach**

134 Compounds were identified by comparing their mass spectra and retention times to those of the standard
135 compounds, or the ones available in the NIST 2.0 mass spectrum library and in the literature. Non-isothermal

136 linear retention indices (LRI), using the definition of Van den Dool and Kratz (1963), were calculated and
137 compared with those available in the literature (Supplementary material, Table S2).

138 Several common ions, only differing in their proportions, characterize the mass spectra of SHs. Therefore, a
139 quantitative assessment of SHs was carried out in Extracted Ion Chromatogram (EIC) by selecting the following
140 ions: m/z 69, 93, 107, 119, 135, 157, 159, 161, 189, 200, 202 and 204. The selection of quantification ions was
141 done according to Vichi et al. (2006) and the confirmation ions were the molecular ions m/z 204, 202 or 200.
142 Quantification was carried out by internal standard, considering a response factor equal to 1, and expressed as
143 μg equivalents of IS/kg of oil (Supplementary material, Table S2). According to Vichi et al. (2006), both SH and
144 monoterpenes may be taken into consideration to be studied as genetic or geographic markers of virgin olive oil
145 origin. However, monoterpene content suffers higher variability due to their low-boiling point compared with
146 sesquiterpenes, introducing variability not related to the origin into the model (data not shown). Since models
147 developed with sesquiterpene data were successful, it was not considered necessary to also include
148 monoterpenes.

149 **2.3.2. Fingerprinting approach**

150 The EIC of specific SH ions (m/z 93, 107, 119, 135, 157, 159, 161, 189 and 204) were obtained from the Total Ion
151 Current (TIC). The intensities of scans comprised from 18th to the 30th minute (2467 scans) were considered for
152 each ion (2467 scans x 9 ions = 22,203 variables per sample). To solve the retention time shifting, for each
153 selected ion the EICs of the 82 samples were aligned by *icoshift* algorithm in Matlab® (Tomasi, Savorani &
154 Engelsen, 2011). Once aligned, the 9 matrices of the 9 aligned EICs were concatenated conforming a two-way
155 unfolded matrix (82 samples x 22,203 variables).

156 **2.3.3. Chemometrics**

157 Univariate statistical analysis for the profiling approach was carried out with SPSS software v25© (IBM Corp., NY
158 USA). A one-way ANOVA was applied: F test and Tukey multiple comparisons test were used when variances
159 were equal between groups. Instead, Welch test and Games-Howell multiple comparisons test were applied
160 when groups presented unequal variances. $P < 0.05$ was considered significant.

161 Multivariate analysis of profiling and fingerprinting approaches was performed with SIMCA software v13.0©
162 (Umetrics AB, Sweden). After data pre-processing (log10, mean centering and scaling for the target data; first
163 derivative, log10, mean centering and scaling for the fingerprint data), a Principal Component Analysis (PCA) was
164 developed for both profile and fingerprint data to explore the natural grouping of samples and detect potential
165 outliers (according to Hotelling's T^2 range and distance to the model parameters). Partial Least Square-
166 Discriminant Analysis (PLS-DA) classification models were built with data obtained by profiling (34 variables) and
167 fingerprinting analysis (22,203 variables) to verify the geographical origin of EVOO samples coming from 7
168 different countries: HRV, SVN, ESP, ITA, GRC, MAR and TUR. PLS-DA is a supervised discriminant technique based
169 on finding the maximum correlation between the data (the SH profile or the SH fingerprint) and each of the
170 categories (each of the seven countries of origin). By doing this, PLS-DA finds the most different features between
171 categories while minimizing those variables not related with a given category. The models were internally
172 validated by leave 10% out cross-validation and the number of latent variables of PLS-DA models were selected
173 according to the lowest RMSEcv value. Model successfulness was evaluated by their prediction power (Q^2 value)
174 and the % of correct classifications. Random behavior and model over-fitting were assessed through the ANOVA
175 on the cross-validated predictive residuals (p-value) and the permutation test, in which the prediction power (Q^2
176 value) of 20 models developed after randomizing sample categories (countries) was compared with that of the
177 original model.

178 **3. Results and Discussion**

179 **3.1. Profiling approach**

180 The chromatograms obtained extracting typical SH ions from the TIC, showed an extremely complex fraction
181 (**Figure 1**). As commented above, the identification of SHs is a challenging task because they present very similar
182 mass spectra. Despite this fact, a total of 34 peaks were included in the SH profile; 23 of them were assigned to
183 previously reported SH ([Bortolomeazzi et al., 2001](#); [Vichi et al., 2006](#)) while the remaining ones were not found
184 in literature but could be related to SH compounds based on their mass spectra. The quantitative data of these
185 SHs, expressed as μg equivalents of IS/kg of oil, were used to perform the univariate statistical analysis by a one-

186 way ANOVA (**Supplementary material, Table S2**). Although some differences were found for some SHs, the high
187 intra-class and inter-class variability caused that this univariate approach was not successful in distinguishing the
188 various origins and that specific markers of origin could not be directly found.

189 Multivariate techniques under a profiling and a fingerprinting approach were assayed in order to better explore
190 the differences between samples from different countries. In the profiling approach, after data pre-treatment
191 and PCA exploration, no outliers were detected. Therefore, the PLS-DA classification model for the targeted data
192 was developed with all the samples (n=82) (**Figure 2a**). After various pre-processing techniques assayed, the
193 model on the log10, mean centering and data scaling to unit variance was the most successful, and with 8 latent
194 variables it achieved the lowest global RMSEcv for most of the categories.

195 **Table 1** shows the classification results obtained from cross-validation by leave 10%-out and the respective
196 RMSEcv values for each class. The model rendered good percentages of correct classification for samples from
197 certain geographical origin, such as SVN (100%), TUR (100%) and MAR (93.3%). However, in the case of oils from
198 the rest of the countries, it generated some misclassifications, particularly in the case of HRV (45.5%), resulting
199 in a non-satisfactory model. This agrees with the fact that the global Q^2 score (0.351) was low, which indicates a
200 low prediction power of the present classification model. On the other hand, the ANOVA p-value (0.013) indicates
201 that the model is significant and thus, that the classification is not at random. Also, the Q^2 values of the
202 permutation test for each category were below 0 indicating the absence of a random classification and of model
203 overfitting.

204 As aforementioned, the target analysis is limited to the number of compounds that can be identified or
205 tentatively identified based on their mass spectrum and linear retention index (LRI). However, the
206 chromatograms obtained by extracting typical terpene fragment ions (**Figure 1**) show that the SH fraction is much
207 more complex, and that many SHs might have not been considered, meaning that the profiling approach might
208 have missed part of the information of the SHs profile.

209 **3.2. Fingerprinting approach**

210 With the aim to extract exhaustive information from the SH fraction in EVOO, a non-target fingerprinting analysis
211 was evaluated. All data points obtained from the selected region of each SH specific EIC were used as variables
212 so that every signal related to SH was taken into account by the model.

213 The two-way unfolded matrix obtained (82 samples x 22,203 variables) was subjected to data pre-processing and
214 PCA exploration, in which any outlier was detected. Then, a PLS-DA classification model was performed. The
215 model leading to the lowest RMSEcv used 6 latent variables (**Figure 2b**). In this case, the sample grouping
216 according to the origin was drastically improved compared to the profiling model. A 100% of correct classification
217 (by leave 10%-out cross-validation) was obtained for each of the 7 countries of origin (**Table 1**). ANOVA p-value
218 (1.6×10^{-18}) indicated that the model was significant and excluded a random classification. Results from the
219 permutation test were very satisfactory, with Q^2 values below 0.2, suggesting that the optimized classification
220 model was not over-fitted.

221 The successful classification results obtained under this approach agreed with the fact that the sub-models for
222 each geographical origin found patterns of the SH fingerprint that were characteristic of each of them, as
223 revealed by the regression coefficient plots (**Supplementary material, Figure S1**). To illustrate this, a section of
224 EIC for m/z 119 of TUR samples (**Figure 3a**) is plotted against the corresponding regression coefficients of the
225 SHs fingerprint of TUR sub-model (**Figure 3b**). It reveals that some of the highest regression coefficients
226 corresponded to peaks (i.e. peaks 7, 9, 13 and 17) that had been quantified with the m/z 119 and included in the
227 profiling model. Nevertheless, other significant regression coefficients were related with parts of the EIC that
228 had not been included in the profiling approach, such as minor SHs or not well-resolved peaks. Thus, this explains
229 the higher discrimination power of the fingerprinting approach compared to the profiling approach.

230 This prospective study sets SHs as successful EVOO geographical markers because even if various monovarietal
231 EVOOs and EVOO cultivar blends were included for each geographical origin (Supplementary material, Table S1),
232 the country of origin was correctly verified. This is because PLS-DA was supervised per geographical origin
233 (country), and thus the model was addressed to focus on the SHs features more related to the geographical area,
234 beyond the cultivar. This means that the PLS-DA model finds features that are common between samples from

235 the same region even if they are from different cultivars. In this way, even if in some cases the same cultivar was
236 present in different countries [‘Arbequina’, ‘Leccino’ and ‘Istrska belica’ (**Figures 4a, 4b and 4c**, respectively)],
237 the model correctly classified the samples into the country of origin. This is especially relevant because it is known
238 that genetic factors influence EVOO’s SH profile (Guinda, Lanzon & Albi, 1996; Osorio-Bueno, Sanchez-Casas,
239 Montaña García & Gallardo González, 2005; Vichi et al., 2010). However, here, thanks to the sampling design
240 and to the ability of PLS-DA to extract information from the fingerprint correlated with the discriminated
241 characteristic (origin in this case), the influence of pedoclimatic aspects on SHs could be exploited.
242 On the other hand, it is noteworthy that although the model was supervised per country of origin, it naturally
243 grouped samples into smaller sub-regions within the same country (although the sub-region information had not
244 been provided to the model). **Figure 5** illustrates this behavior by exemplifying the case of Italian and Turkish
245 oils, where samples from Tuscany, Sicily and Apulia (Figure 5a), and samples from North Aegean, Germencik and
246 Antakya (Figure 5b), respectively, conform independent clusters within each class. This entails that the SH
247 fingerprint holds similar traits among samples from regions smaller than a country and sets a promising scenario
248 for downscaling the model to verify the geographical origin of EVOO produced in smaller regions of interest such
249 as those from protected designations of origin (PDO) or protected geographical indications (PGI).

250 **4. Conclusions**

251 This prospective study focused on the suitability of SHs as EVOO geographical markers and the evaluation of the
252 best approach for data processing, allowed us i) to confirm that SH can be successfully used for the verification
253 of EVOO geographical origin, ii) to state that the fingerprinting approach provided a model with a higher
254 discrimination capacity (100% correct classification) with respect to the targeted profiling one (from 46 to 100%
255 correct classification, depending on the country). It is remarkable that this classification rate was achieved under
256 a real scenario of EVOO global production, which implied the use of various monovarietal and blends of oils from
257 cultivars typically produced and marketed in each country. Also, samples from the same olive cultivar coming
258 from different countries were correctly classified according to the geographical origin. Moreover, as the SH
259 fingerprint holds similar traits among samples from sub-regions within a country, it sets a promising scenario for

260 downscaling the model to smaller regions of interest such as PDO or PGI oils, as well as for challenging model
261 robustness with samples for various harvest years. Actually, evaluating the effect of the harvest year has been
262 shown to be crucial for some authentication models developed for EVOO verification, because as reviewed by
263 Tres et al. (2013) the differences in the climatic conditions might affect EVOO composition.

264 Overall, we can conclude that the successfulness of the model is the result of a conjunction of factors: i)
265 sesquiterpenes are suitable geographical markers, ii) the use of the sesquiterpene fingerprint permits to exploit
266 all the information obtained during the analysis in contrast of the target approach, and iii) PLS-DA finds features
267 in the sesquiterpene fingerprint that are common between samples from the same region even if they belong to
268 different cultivars. Although we are aware that an increment of samples (with more samples from these and
269 other origins, and from different harvest years) and external validation are still necessary to develop a more
270 robust and elaborated model for the classification of samples according to their geographical origin, these
271 preliminary results confirm the suitability of SHs as geographical markers and set the basis for the most efficient
272 approach for the treatment of SH analytical data with this purpose up to date.

^a Profiling PLS-DA model: Q²: 0.351; ANOVA p-value: 0.013;

^b Fingerprinting PLS-DA model Q²: 0.561; ANOVA p-value: 1.6^{e-18}.

Highlights

- Geographical authentication models developed with virgin olive oil sesquiterpene (SH) data
- The suitability of SH as virgin olive oil geographical markers was confirmed
- Better classification by SH fingerprinting (100%) than by profiling (46-100%)
- SH fingerprinting set a promising scenario for downscaling the model to smaller regions
- The efficiency of the model by geographical origin was independent from the cultivar

Figure S1. PLS regression coefficients of fingerprinting PLS-DA classification model, resulting from each data point of the m/z 119 EIC vs each country of origin: a) Croatia (HRV); b) Slovenia (SLO); c) Spain (ESP); d) Italy (ITA); e) Greece (GRC); f) Morocco (MAR) and g) Turkey (TUR). The highest coefficients are in red.

Table S1. List of EVOO cultivars per country included in the sampling of monovarietal and cultivar blends.

Country	EVOO variety (monovarietal and cultivar blends)
Croatia (HRV, n=11)	Buza puntoza Istrska belica Oblica Picholine Ascolana tenera / Itrana / Frantoio blend Buza puntoza / Rosijnola / Bova blend Leccino / Pendolino blend Picholine / Leccio del Corno blend Plominka/Simjaca
Slovenia (SVN,n=8)	Istrska belica Istrska belica / Leccino / Maurino blend Istrska belica / Leccino / other varieties blend
Spain (ESP, n=17)	Arbequina Hojiblanca Manzanilla Picual Arbequina / Hojiblanca blend Hojiblanca / Picual blend
Italy (ITA, n=15)	Arbequina Biancolilla Castiligionese Coratina Frantoio Coratina / Ogliariola blend Leccino / Frantoio / Moraiolo blend Leccino / Frantoio / Pendolino blend Nocellara del Belice Nostrana di Brisighella
Greece (GRC, n=6)	Arbequina Koroneiki Manaki
Morocco (MAR, n=15)	Arbosana Arbequina Koroneiki Picholine Picholine / Hojiblanca blend
Turkey (TUR, n=10)	Ayvalik Domat Memecik Ayvalik / Domat blend Karamani / Hasebi blend Memecik / Gemlik blend

Table S2. Characterization of sesquiterpene hydrocarbons in samples: quantification and confirmation ions, Linear Retention Index (LRI) of identified compounds in comparison to those reported in literature and mean values with standard deviation calculated by country between parentheses. Significant statistical differences between groups (by ANOVA) are shown. Compounds have been tentatively identified by mass spectra and retention indices.

Abbreviations used: HRV: Croatia, SVN: Slovenia, ESP: Spain, ITA: Italy, GRC: Greece, MAR: Morocco; TUR: Turkey; ni: not identified compound; nd, not detected

^a Ion used for quantification

^b Molecular weight (confirmation ion)

^c Calculated linear retention indices

^d Literature linear retention indices

^e Significance value, according to one-way ANOVA: *, P≤0.05; ** P≤0.01

^f Unequal variances between groups: ANOVA performed with Welch test and multiple comparisons test carried out by Games-Howell test.
