Comparative cost-effectiveness of dynamic contrast-enhanced computed tomography versus positron emission tomography in the characterisation of solitary pulmonary nodules: the SPUtNIk trial
D. Tzelis[1], F. J. Gilbert[2], L. Vale[1], V. Benedetto[3], A. Clegg[3], S. Harris[4], J. R. Weir-McCall[2], K. Miles[5], S. George[4]; [1]*Newcastle/UK,* [2]*Cambridge/UK,* [3]*Preston/UK,* [4]*Southampton/UK,* [5]*Brighton/UK (jweirmccall@doctors.net.uk)*

Purpose: To compare the cost-effectiveness of dynamic contrast-enhanced computed tomography (DCE-CT) and ^{18}Fluorine-Fluorodeoxyglucose positron emission tomography/computed tomography (PET-CT) based approaches for the diagnosis of solitary pulmonary nodules (SPN).
Methods and materials: In this prospective multicentre trial, 380 participants with indeterminate SPN (8-30 mm) underwent DCE-CT and PET-CT. All patients completed 2 years follow-up with a collection of subsequent investigations, management strategy, and outcome. The cancer prevalence, diagnostic accuracy, and test outcome results of the SPUtNIk trial were used in an economic evaluation decision model. Further data on complications of the tests and survival came from a systematic review and meta-analysis. NHS tariff costs and the literature were used for cost estimates. The economic evaluation was reported as a cost-consequence analysis and the incremental cost per correctly managed case over a two-year time horizon was also calculated.
Results: Sequential DCE-CT and PET-CT were most accurate (84.4±1.4%) for the management of SPN compared with DCE-CT (77.8±2%) or PET-CT alone (82±1.6%). However, the combined modality approach was most costly in the cost-consequence analysis (£4058±210). A DCE-CT strategy was the least costly (cost=£3305±199) followed by PET/CT (£4014±206). For all correctly managed cases, the ICER for DCE-CT/PET-CT over DCE-CT was £11,323. For DCE-CT/PET-CT versus DCE-CT, the incremental cost per correctly managed case was £11,323. PET/CT would not be cost-effective compared to either DCE-CT or DCE-CT/PET-CT.
Conclusion: If society is not willing to pay more than £11,323 per accurately managed case, DCE-CT is a cost-effective strategy. Above this value, DCE-CT/PET-CT is the most cost-effective strategy. With the greater availability and access to CT, and lower cost, consideration should be given to using DCE-CT as the first-line test for indeterminate pulmonary nodules.
Limitations: Limited availability of utility data and long-term costs.
Ethics committee approval: REC-12/SW/0206.
Funding: NIHR-HTA (grant no:09/22/117).

Quality assurance in lung cancer screening by computed tomography: optimised ultra-low radiation dose by beam filtering in a randomised study
M. Silva[1], G. Milanese[1], S. Sestini[2], M. Ruggirello[2], A. Marchianò[2], N. Sverzellati[1], U. Pastorino[2]; [1]*Parma/IT,* [2]*Milan/IT (mariosilvamed@gmail.com)*

Purpose: To test different protocols of ultra-low radiation dose computed tomography (ULDCT) by x-ray spectrum shaping for lung cancer screening (LCS).
Methods and materials: Based on a former anthropomorphic phantom study, 375 subjects were prospectively randomised to one of the following ULDCT protocols: fully automated exposure control (both voltage and current - "ULDCT1"), fixed tube voltage (Sn100kVp) and current according to patient size (140mAs or 210mAs – "ULDCT2"), and a hybrid approach with fixed tube voltage and automatic exposure control for current ("ULDCT3" Sn100-100refmAs and "ULDCT4" Sn150-20refmAs). Each subject underwent double CT acquisition with one of the above protocols and the low-dose CT (LDCT: 120kVp, 25mAs). Intrasubject CT dose index (CTDIvol) and dose-length product (DLP) were compared (mean and standard deviation reported). An analysis of variance to compare ULDCT protocols was undertaken.
Results: CTDIvol was 1.62 (0) mGy in LDCT compared to ULDCT: 0.59 (0.21), 0.72 (0.15), 0.51 (0.16), and 0.66 (0.17).
DLP was 65 (6) mGycm in LDCT compared to ULDCT: 24 (8), 29 (7), 21 (7), 27 (8).
ULDCT3 showed lower CTDIvol than any ULDCT protocol ($p<0.001$) and lower DLP than ULDCT2 and 4 ($p<0.001$). Conversely, ULDCT2 appeared the less convenient approach for dose saving, with CTDIvol and DLP higher than ULDCT1 and 3 ($p<0.001$).
Conclusion: Optimised ULDCT protocols with x-ray spectrum shaping by tin-filter can be used with fixed tube voltage at Sn100 kVp and automatic control of tube current (ULDCT3) to aim at the sharpest optimisation of radiation dose. Fixed techniques are less effective in reducing doses.

Limitations: Image quality will be tested for consistency of each optimised protocol within LCS workflow by dedicated post-processing platform (detection and semi-automatic volume of nodule).
Ethics committee approval: Prot INT 21/11 and further amendments.

RPS 1404a-6 11:45
Improving diagnostic accuracy for pulmonary nodules with the combination of morphological characteristics and spectral CT-specific multiparameters
Z. Ren, T. He*; Xianyang/CN*
(rzl19900220@163.com)

Purpose: To demonstrate the value of improving pulmonary nodules (PN) diagnostic accuracy by combining the morphological characteristics and spectral CT-specific parameters.
Methods and materials: 173 patients with pulmonary nodules (61 benign pulmonary nodules (BPN) and 112 malignant pulmonary nodules (MPN)) underwent dual-phase contrast-enhanced spectral CT. Monochromatic and material decomposition images were reconstructed. The morphological characteristics of PN were observed on 70keV images. The CT values from 40keV to 140keV, Effective-Z, blood concentration (BC), iodine concentration (IC), water concentration (WC) of PN, and the aorta at the same level were measured to calculate the slope of spectral HU curve (λ), normalised blood concentration (NBC), normalised iodine concentration (NIC), and normalised water concentration (NWC). The receiver operating characteristic (ROC) curve was drawn to evaluate the diagnostic performance of differentiating BPN from MPN.
Results: The two patient groups were similar demographically (P>0.05). The incidence of bronchial truncation, irregular shape, lobulation, pleural effusion, and vascular invasion in MPN was significantly higher than those in BPN (P<0.05). The CT values from 40keV to 90keV, $\lambda_{40keV\text{-}90keV}$, $\lambda_{100keV\text{-}140keV}$, $\lambda_{40keV\text{-}140keV}$, BC, IC, NBC, NIC, and Effective-Z values of BPN were significantly higher than those of MPN (P<0.05), while both lesions had similar CT values from 100keV to 140 keV and WC and NWC values (P>0.05). The diagnostic accuracy in differentiating BPN and MPN (AUC 0.891) with combined morphological characteristics and spectral CT-specific parameters was significantly higher than that of only using morphological characteristics (AUC 0.726) or spectral multiparameters (AUC 0.843).
Conclusion: Morphological characteristics with a combination of spectral CT multiparameter spectral CT can help to improve the diagnostic accuracy in differentiating pulmonary nodules.
Limitations: Tha sample size was small.

Using spirometry to identify high-risk individuals not eligible for lung cancer screening
R. Aggarwal, A. Lam, G. Liu, J. Kavanagh*; Toronto/CA (jokavana@tcd.ie)*

Purpose: To determine if FEV1 can identify a high-risk subgroup of individuals traditionally excluded by current lung cancer screening eligibility criteria.
Methods and materials: Spirometry (2009-2013) was administered in a lung screening program and patient outcomes were tracked until 2017. The addition of forced-expiratory-volumes-at-one second, FEV1, to four different screening-eligibility criteria, (DLST, NLST, NELSON, and OLSP) was retrospectively assessed to identify high-risk individuals. Sensitivity, specificity, and the number needed to screen at various FEV1 cutoffs were compared to determine the optimal clinical cutoff.
Results: In 1,161 participants, optimal clinical cutoffs for FEV1 were 90%, 90%, 90%, and 85% for the DLST, NLST, NELSON, and OLSP, respectively. Respectively, the sensitivity was increased significantly by 33%, 28%, 28%, 16%, specificity was reduced by 19%, 25%, 24%, 22%, and NNS was reduced by 122, 7, 10, -3 when compared to original criteria alone.
Conclusion: Spirometry can identify a high-risk subpopulation missed by original lung screening criteria, particularly when self-reported COPD is not included. Inclusion of spirometry-identified airway obstruction screening-eligibility criteria into screening programs that lack another method for COPD assessment increases sensitivity.
Limitations: A retrospective single-institution study. The FEV1 cutoffs were chosen by the authors pragmatically to maximise sensitivity as well as keeping specificity acceptable.
Ethics committee approval: Approval was obtained through the University Health Network (UHN) Research Ethics Board (REB 06-0639). Recruitment began in June 2003 and concluded in December 2009 as part of the Lusi Wong Princess Margaret Early Lung Cancer Detection Program (PM-ELCAD).
Funding: This study was supported by the Lusi Wong Fund, the Princess Margaret Cancer Foundation, the Alan Brown Chair in Molecular Genomics (to GL), and the University of Toronto Comprehensive Research Experience for Medical Students programme.

RPS 1404a-8 11:57
Pulmonary nodule growth: can follow-up be shortened with a high-end or an ultra-high-resolution CT scanner?
D. Grob, S. Schalekamp, L. J. Oostveen, W. J. van der Woude, C. Jacobs, M. M. Prokop, I. Sechopoulos, M. Brink*; Nijmegen/NL*
(Dagmar.Grob@radboudumc.nl)

Purpose: To determine the interscan variability of pulmonary nodule volume measurements in CT scans acquired with state-of-the-art wide-area and ultra-high-resolution CT systems.
Methods and materials: In this prospective study, patients with at least two non-calcified solid pulmonary nodules suspicious for metastases on previous CT scans were imaged twice with either a high-end 320-detector CT (MDCT, Aquilion ONE Genesis, Canon, slice thickness 0.5 mm, 512x512 matrix) or an ultra-high-resolution CT (UHRCT, Precision, Canon, 0.25 mm, 1024x1024). In between scans, an off-and-on table strategy was used to simulate follow-up scans with no nodule growth. Semi-automated volumetric nodule segmentation and volume estimation (max. 4 per patient, effective diameter 4-15 mm) were performed on a lung screening workstation (Veolity). 95%-limits of agreement (LOA) and the time to estimate actual nodule growth rate at a nodule volume doubling time (VDT) of 400 days were calculated.
Results: 17 patients (60 nodules, average volume: 218 mm^3) were imaged on the MDCT and 27 patients (90 nodules, 177 mm^3) on the UHRCT at a similar dose (mean dose-length-product: 126.6 mGycm vs. 127.2 mGycm, respectively (p=0.98)). The 95%-LOA was ±7.0% for the MDCT and ±5.9% for the UHRCT (p=0.07). Therefore, the minimum required interscan period to detect a VDT of 400 days is only 33-39 days.
Conclusion: Both scanners result in low interscan variability, especially compared to current clinical standards, which requires a volume change of 25% (the current 95%-LOA) as significant nodule growth. Therefore, the follow-up period to detect pulmonary nodule growth could be dramatically shortened from three to about one month, reducing patient anxiety and the potential for stage shift in lung nodule management.
Limitations: Pulmonary metastases instead of incidental nodules were measured.
Ethics committee approval: Review board approval and written informed consent were obtained.
Funding: Canon provided financial funding.

RPS 1404a-9 12:03

The classification of pulmonary nodules by Lung-RADS 1.1: a randomised prospective analysis of four ultra-low dose CT protocols in a lung cancer screening trial

G. Milanese[1], M. Silva[1], M. Ruggirello[2], S. Sestini[2], F. Sabia[2], A. Marchianò[2], N. Sverzellati[1], U. Pastorino[2]; [1]Parma/IT, [2]Milan/IT

Purpose: To analyse the intrasubject agreement between low-dose (LDCT) and ultra-low-dose CT (ULDCT) for LungRADS1.1 in a lung cancer screening (LCS) setting.
Methods and materials: 375 subjects underwent single-breath-hold double CT acquisition protocol, including both standard LDCT scan (120kVp, 25mAs) and one of the following ULDCT protocols: fully automated exposure control ("$ULDCT_1$"), fixed tube-voltage and current according to patient size ("$ULDCT_2$": Sn100kVp, 140mAs/210mAs), or hybrid approach with fixed tube-voltage and automated exposure control for current ("$ULDCT_3$": Sn100kVp-100mAs_{ref}; "$ULDCT_4$": Sn150kVp-20mAs_{ref}).
Prospective LDCT reading was performed by semi-automatic software for the detection and segmentation of pulmonary nodules (PN). After a wash-out time of at least 2 weeks, two independent readers repeated the same process on ULDCT, without manual corrections. Dominant PNs (dPNs) were selected from both LDCT and ULDCT according to volumetric LungRADS1.1.
Agreement was assessed by means of Cohen's weighted-kappa test.
Results: Intrasubject inter-scanning protocol variation for LungRADS1.1 was: κ_{ULDCT1}=0.8461, κ_{ULDCT2}=0.9030, κ_{ULDCT3}=0.8813, and κ_{ULDCT4}=0.9033 for $Reader_1$, and κ_{ULDCT1}=0.8469, κ_{ULDCT2}=0.9029, κ_{ULDCT3}=0.7896, and κ_{ULDCT4}=0.7844 for $Reader_2$.
Inter-reader agreement by ULDCT was: κ_{ULDCT1}=0.8726, κ_{ULDCT2}=0.8899, κ_{ULDCT3}=0.8466, and κ_{ULDCT4}=0.8590.
$Reader_1$ missed dPNs in 11/98 (11.2%) $ULDCT_1$, 12/94 (12.8%) $ULDCT_2$, 16/88 (18.1%) $ULDCT_3$, and 14/95 (14.7%) $ULDCT_4$. Missing of LDCT dPNs did not affect management by $ULDCT_3$.
$Reader_2$ missed dPNs in 13/98 (12.2%) $ULDCT_1$, 9/94 (9.6%) $ULDCT_2$, 11/88 (12.5%) $ULDCT_3$, and 8/95 (8.4%) $ULDCT_4$. Missing of LDCT dPNs would have affected management by $ULDCT_3$ for 1 subject (shift from $LungRADS_3$ to $LungRADS_2$).
Conclusion: Intrasubject and inter-reader agreement for LungRADS between LDCT and ULDCT ranged from good to very good. $ULDCT_3$ scanning protocol can be proposed for the purposes of LCS.
Limitations: Single CT and CAD used.
Ethics committee approval: Prot-INT21/11 and further amendments.

Deep learning in discriminating atypical lung nodules: a diagnostic test

Y. Zhang[1], Y. Liu[1], H. Han[2], F. Qu[1], N. Huang[2], Z. Ye[1]; [1]Tianjin/CN, [2]Beijing/CN

Purpose: To test the feasibility and efficiency of a deep learning model to discriminate challenging atypical lung nodules.
Methods and materials: 5,912 surgically confirmed benign nodules since 2014 were initially included. Then preliminary screening was performed by three radiologists to filtrate atypical nodules following longest-diameter ≤3cm, part-solid or solid, no calcification, or adipose inside nodule on pre-contrast CT slices. So far, a total of 380 nodules including 190 malignant nodules and 190 atypical benign nodules diagnosed in 2019 comprised our research dataset. 24 semantic features and a diagnostic opinion were also recorded. A centre-cropped 3D convolutional neural network (CNN) which has previously proved efficiency in differentiating nodules on low-dose CT scans was trained with the LIDC-IDRI dataset and a private screening dataset. Receiver operating characteristic analysis was performed to evaluate the purposed study. An instance figure was uploaded to demonstrate the radiographic appearance of 4 included nodules.
Results: Only 79 (20.8%) atypical nodules were directly given correct diagnosis by radiologists without any follow-up suggestion. For initial CNN, the average precision on our dataset was 57.3% and the average AUC was 0.64, with 53.1% sensitivity and 60% specificity. After feeding CNN with additional new atypical samples, the average precision increased to 73% and the average AUC was 0.78, with 78.3% sensitivity and 70.0% specificity.
Conclusion: Deep learning has shown potential in recognising atypical nodules at base-line examinations. However, the critical role of the dataset in our study implies most datasets based on follow-up labels may not be enough. Deepening and broadening of the training dataset probably benefits further application of deep learning in radiology.
Limitations: Sample augmentation is still on-going to overcome distribution overlapping and to further improve performance.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Multi-detector computed tomography diagnosis of the different pathological types of cystic lung cancer

L. Zheng[1], Y. Li[2]; [1]Shanghai/CN, [2]Zhangjiagang/CN
(zhenglinfeng04@aliyun.com)

Purpose: To analyse MDCT findings of different pathological types of cystic lung cancer (CLC).
Methods and materials: 28 cases with pathologically proved CLC were retrospectively collected and general clinical data and MDCT findings were analysed. Then imaging features of these CLC were further interpreted including lesion size, location, morphological classification, ground-glass opacity sign, shape, margin, tumour-lung interface, the relationship of tumour and bronchus, residual separation in the airspace, pleural indentation, and associated bullae.
Results: Of 28 CLC cases, 18 cases of adenocarcinomas, 3 cases of microinvasive adenocarcinomas, 6 cases of squamous carcinomas, and one adenosquamous carcinoma. The average age of patients in the adenocarcinoma cases and the squamous cell carcinoma cases were 60.56±8.03 and 66.00±7.93 years old, respectively, which was higher than the microinvasive adenocarcinoma cases (49.33±16.17 years old) (p=0.048). For the lesion size, the cases of adenocarcinoma (1.99±0.69 cm) and squamous cell carcinoma (2.45±0.87 cm) were larger than that of the cases of microinvasive adenocarcinoma (0.73±0.23 cm) (p=0.008). Ground-glass sign was mainly found in adenocarcinoma (14 cases, 77.8%) and microinvasive adenocarcinoma (3 cases, 100.0%), however, only one case (16.7%) of squamous cell carcinoma showed this sign (p=0.012). 5 cases of squamous cell carcinoma showed bronchial cut-off sign, which was more common than in the adenocarcinoma (2 cases) (p=0.003). There were no significant differences for other imaging features in different pathological types of CLC (p>0.05).
Conclusion: For the different pathological type of CLC, there are relatively typical CT imaging findings, e.g. the ground-glass opacity was frequently observed in adenocarcinoma while the bronchial truncation sign was common in squamous cell carcinoma. It is important to do dynamic follow-up CT for atypical lesions of CLC.
Limitations: Small size cases. A lack of follow-up data.

Lung-RADS category and smoking status can predict adherence to recommendations in a real-world low-dose CT lung cancer screening program

E. J. M. Barbosa Jr.[1], M. Hershman[2]; [1]Philadelphia, PA/US, [2]Tucson/US

Purpose: Low-dose CT lung cancer screening (LCS) can decrease lung cancer related mortality in persons with a significant smoking history, however, it is hindered to low adherence to follow up recommendations.
Methods and materials: We retrospectively enrolled all persons who underwent multiple (2 or more) LCS exams from 2014 to 2019 at our institution and recorded patient demographics, lung-RADS category, outcomes, and adherence to screening recommendations. We assessed predictors of adherence via univariate and multivariate logistic regression (MLR).
Results: 260 persons returned for follow-up scans (57.7% had 2, 34.2% had 3, 7.7% had 4, and 0.4% had 5). 43/260 (16.5%) had positive scans, of which 28/260 (10.8%) were lung-RADS category 3, 8/260 (3.1%) were 4A, 6/260 (2.3%) were 4B, and 2/260 (0.8%) were 4X. 143 persons were current smokers at the time of the baseline LDCT and 117 persons were former smokers who quit within the last 15 years before the baseline LDCT. Overall adherence was 43.0% but increased progressively with higher lung-RADS (33.2%-100%) and with former smoker status (50.0%, vs 36.2% for current smokers). Smoking status and a positive lung-RADS category were the only statistically significant predictors of adherence in MLR modelling.

Conclusion: Adherence to LCS recommendations, which is crucial to maximize the benefits of LCS and allow early diagnosis of lung cancer, is less than 50% and is lower in persons who are current smokers and with negative LCS exams, offering a roadmap for targeted performance improvement, which healthcare systems can leverage to improve LCS cost-effectiveness and maximize its societal benefits.
Limitations: A retrospective design.
Ethics committee approval: IRB approved.
Funding: No funding was received for this work.

LI-RADS category 5 hepatocellular carcinoma: preoperative gadoxetic acid–enhanced MRI to predict early recurrence after curative resection
H. Wei, H. Jiang, B. Song*; Chengdu/CN (weih_cat@163.com)*

Purpose: To identify preoperative gadoxetic acid enhanced-magnetic resonance (MR) imaging biomarkers for prediction of early recurrence (2 years) after curative resection for liver imaging reporting and data system category 5 (LR-5) hepatocellular carcinoma (HCC).
Methods and materials: Between July 2015 and July 2018, this retrospective study evaluated consecutive treatment-naïve, high-risk patients who underwent gadoxetic acid–enhanced MR examination within 1 month before surgical resection for HCC. All MR images were reviewed by two independent radiologists. Predictive clinical and imaging features for early recurrence were identified by univariate and multivariate analysis.
Results: A total of 126 patients with 167 LR-5 HCCs were included; 62 (49.2%) patients had postoperative tumour recurrence within 2 years. Four MR imaging features and serum AFP were independently associated with early recurrence: peritumoural hypointensity on hepatobiliary phase (HBP) (odds ratio [OR] = 6.68; 95% CI: 1.437, 31.081), corona enhancement (OR = 3.997; 95% CI: 1.238, 12.905), tumour size >5 cm (OR = 3.629; 95% CI: 1.137, 11.586), multifocality (OR = 3.141; 95% CI: 1.011, 9.763), and AFP level > 400 ng/mL (OR = 3.262; 95% CI: 1.242, 8.569). The AUCs of the combined models comprising only predictive MR imaging features and MR features along with serum AFP were 0.783 (95% CI: 0.704, 0.862) and 0.797 (95% CI: 0.719, 0.875), respectively.
Conclusion: In high-risk patients with LR-5 HCC, preoperative HBP peritumoral hypointensity, corona enhancement, tumour size, multifocality, and serum AFP can be used to predict early recurrence after curative hepatectomy.
Limitations: The retrospective design may cause a selection bias.

RPS 1401-2 11:21

What proportion of clinically reported LI-RADS 5 observations do not meet LI-RADS 5 criteria?
J. Birnbaum[1], C. B. Sirlin[2], V. Chernyak[3]; *[1]Bronx/US, [2]San Diego, CA/US, [3]Bronx, NY/US (vichka17@hotmail.com)*

Purpose: Liver imaging reporting and data system (LI-RADS) category 5 (LR-5) denotes 100% certainty of hepatocellular carcinoma. The assignment of LR-5 is based on combinations of major features (size, arterial phase hyperenhancement [APHE], "washout" [WO], enhancing "capsule", threshold growth). The goal of this study is to assess the proportion of LR-5 observations reported clinically that did not meet LR-5 criteria based on reported major features using LI-RADS v2017 and v2018.
Methods and materials: All MR and CT reports using a standardised LI-RADS macro between 4/17–8/19 were reviewed. For each reported LR-5 observation, all major features and LI-RADS version (v2017 or v2018) were extracted from the clinical report. Based on the reported major features, we determined whether LR-5 criteria were met for each observation.
Results: 237 observations in 181 patients (68% male, mean age 65.6 years) were reported as LR-5, including 137 (58%) reported with v2017 (median size 23 mm) and 100 (42%) with v2018 (median size 18 mm). 9/137 (7%) v2017 LR-5 observations and 4/100 (4%) v2018 LR-5 observations did not meet LR-5 criteria based on reported major features. Of the 9 incorrectly categorised v2017 observations, 3 (33%) lacked APHE, 1 (11%) was < 10 mm, 1 (11%) was 16 mm new observation with APHE only, and 4 (44%) were 10-19 mm with APHE and WO as the only other major feature. Of the 4 incorrectly categorised v2018 observations, 3 (75%) lacked APHE and 1 (25%) was < 10 mm.
Conclusion: Based on reported major features, 4-7% of clinically reported LR-5 observations do not meet LR-5 criteria. Methods such as education and decision support tools may help to reduce the frequency of these reporting errors.
Limitations: Retrospective single institution study.
Ethics committee approval: IRB-approved. Informed consent was waived.
Funding: No funding was received for this work.

Diagnostic criteria for recurrent hepatocellular carcinoma in gadoxetic acid enhanced MRI: are LR4 observations enough for the diagnosis of recurrence?
H. Kim, J.-I. Choi, S. Y. Youn, D. W. Kim, S. E. Rha*; Seoul/KR (heesoo2423@gmail.com)*

Purpose: Current diagnostic criteria for HCC are focusing on HCC naïve patients and there are no established diagnostic criteria for recurrent HCC. We evaluated the diagnostic performance of LI-RADS version 2018 using gadoxetic acid-enhanced MRI in patients with a prior history of HCC.
Methods and materials: We enrolled 51 consecutive patients who: 1) underwent liver transplantation or resection for HCC between 2013 to 2018 in our institute, 2) had gadoxetic acid-enhanced MRI within one month before transplantation or resection, 3) prior history of treatment of HCC, and 4) did not have more than five HCCs or infiltrative tumours. Two radiologists reviewed gadoxetic acid-enhanced MRIs and determined the presence of LR3, LR4, and LR5 observations except previously treated tumours based on LI-RADS version 2018 in consensus.
Results: Sensitivity for recurrent HCC of LR5 and LR5+LR4 observations were 32.4% and 89.2%, respectively. PPV for LR5, LR4, and LR3 observations were 100%, 70.0%, and 44.4%, respectively. 100% of LR4 observations determined by major features only (LR4m) were HCC. But PPV of LR4 observations upgraded from LR3 using ancillary features (LR4u) was 62.5%. For LR4u observations, PPV of observations with arterial enhancement (LR4ua) and without arterial enhancement (LR4un) were 81.3% and 25.0%, respectively. Sensitivity and PPV for LR5+LR4n+LR4ua observations were 83.7% and 91.2%, respectively.
Conclusion: The sensitivity of LR5 observations for the detection of recurrent HCC was very low. Regarding LR4 observations as HCC reduces the PPV. Presuming LR4 observations with arterial enhancement as HCC may compromise both sensitivity and PPV.
Limitations: Selection bias for retrospective design.
Ethics committee approval: IRB approved this study and waived informed consent.
Funding: National R&D Program for Cancer Control, Ministry of Health & Welfare, and Republic of Korea (HA15C0004).

Indeterminate lesions (LI-RADS 3 and 4) lacking arterial phase hyperenhancement on CT and MRI in the cirrhotic liver: outcome and role of ancillary features

A. Inzerillo[1], G. Porrello[2], F. Vernuccio[2], R. Cannella[2], M. Midiri[2], G. Brancatelli[2]; [1]Lascari/IT, [2]Palermo/IT (inzerilloagostino@gmail.com)

Purpose: To retrospectively evaluate LI-RADS ancillary imaging features and outcomes of indeterminate lesions lacking APHE in cirrhotic patients.
Methods and materials: In this retrospective study, we included indeterminate lesions (LR-3 and LR-4) up to 3 cm lacking APHE in consecutive cirrhotic patients imaged with CT or MRI. All MRI exams were performed with Gd-EOB-DTPA. All lesions were individually evaluated to determine LI-RADS major and ancillary imaging features at diagnosis and outcome. Reference standard was based on pathology and imaging follow-up.
Results: 27 lesions lacking APHE, 20 LR-3 and 7 LR-4, in 12 cirrhotic patients (10M, 2F) were included. HCC was proved for 4 [15%] of 27 lesions, including 1 of 10 (10%) lesions imaged with CT, and 3 of (17%) 17 lesions imaged with MRI. Not-HCC malignancy was diagnosed in 1 lesion imaged with MR. Imaging analysis of these 5 malignant lesions showed none of the ancillary features suggesting malignancy on the lesion imaged with CT. Conversely, at least one ancillary feature suggesting malignancy was detected in the remaining 4 lesions imaged with MR (i.e., hepatobiliary phase hypointensity in 4, restricted diffusion in 3, fat in the mass in 3, and T2-hyperintensity in 2).
Conclusion: HCC is identified in 10% and 17% of indeterminate LR-3 or LR-4 lesions lacking APHE imaged with CT or Gd-EOB-DTPA MRI, respectively. MRI may allow the detection of LI-RADS ancillary features suggesting malignancy and therefore those lesions requiring more aggressive management.
Limitations: Small sample size, retrospective design, no inter-reader assessment.
Ethics committee approval: IRB approved, waiver of informed consent obtained.
Funding: No funding was received for this work.

Modified LI-RADS for diagnosis of hepatocellular carcinoma on gadoxetic-acid-enhanced MR imaging: a prospective comparative study

Y. Qin, H. Jiang, B. Song; Chengdu/CN (qinyun@wchscu.cn)

Purpose: To develop modified liver imaging reporting and data systems (mLI-RADS) with gadoxetic acid-enhanced magnetic resonance imaging (EOB-MRI) and compare its diagnostic accuracy with the original version 2018 (v2018) LI-RADS for hepatocellular carcinoma (HCC) in high-risk patients.
Methods and materials: Totally 278 patients with 885 nodules (440 HCCs, size range: 0.3-14.6 cm) were enrolled from July 2015 to October 2018 and underwent EOB-MRI. Major and ancillary imaging features and LI-RADS categories of all liver observations were evaluated based on v2018 LI-RADS by two independent radiologists. We constructed four mLI-RADS with: i) restricted diffusion and hepatobiliary phase hypointensity upgraded as additional major features (M1), ii) "capsule" instead of enhancing "capsule" regarded as an additional major feature (M2), iii) size categories of "＜10 mm" and "10-19 mm" combined as "＜20 mm" (M3), and iv) M1+M2+M3 (M4). Per-lesion sensitivity and specificity of these criteria were compared using McNemar's test.
Results: Per-lesion sensitivity, specificity, and accuracy by consensus were 59%, 98%, and 78% for LR-5 or LR-TIV contiguous with LR-5 mass with v2018 LI-RADS. These measures were 68%, 97%, and 81% for M1, 60%, 98%, and 78% for M2, 73%, 98%, and 85% for M3, and 75%, 97%, and 86% for M4. M1 ($p=0.003$), M3 ($p<0.001$), and M4 ($p<0.001$) all demonstrated significantly higher sensitivity than v2018 LI-RADS without substantial affect of specificity (p=0.290-1.000).
Conclusion: Compared with v2018 LI-RADS, mLI-RADS on EOB-MRI exhibits diagnostic advantages for HCC in high-risk patients.
Limitations: All lesions of every patients were enrolled, but bootstrap analysis was not used to handle clustering effect.
Ethics committee approval: Ethical approval by the institutional review board and informed consent were obtained.
Funding: No funding was received for this work.

Analysis imaging features of LI-RADs M on MRI using hepatocyte-specific agent and correlation with pathologic diagnosis

K. Lim, H. Kwon, J. Cho; Pusan/KR (nonomori85@naver.com)

Purpose: To analyse the image features for the diagnosis LI-RADs M on MRI using hepatocyte-specific agent and its correlation with pathologic diagnosis.
Methods and materials: Between March 2016 and February 2019, 65 LI-RADS M underwent MRI at 3T using a hepatocyte-specific agent and pathologic confirmation. Two independent radiologists evaluated the presence or absence of rim enhancement, peripheral washout, delayed central enhancement, targeted on TP or HBP, targeted restriction, infiltrative pattern, marked diffusion restriction, necrosis, severe ischemia and biliary dilatation, and surface retraction of each observation. The agreement of image features was assessed with an intraclass coefficient (ICC). The frequency of consensus image features was analysed and compared with pathologic diagnosis using the paired t-test.
Results: The agreement of image features was moderate to excellent. On pathologic diagnosis, there were HCC (35.4%), IHCC (27.7%), HCC-CC (7.7%), metastasis (15.4%), inflammation (10.8%), and rarely sarcoma, lymphoma (<5%). The biliary dilatation and surface retraction was significantly correlated to IHCC ($p<0.05$). The infiltrative pattern was correlated to chronic inflammation. Other image features were not correlated to specific pathologic diagnosis.
Conclusion: The presence of LR-M features and biliary dilatation or capsular retraction may be helpful in the diagnosis of IHCC without a biopsy. If only LR-M image features without biliary dilatation or capsular retraction are present, then a biopsy is essential for the accurate diagnosis. However, the infiltrative pattern may be an inflammatory disease which is not malignant, so it should be carefully considerate when making a diagnosis.
Limitations: A small number studied. Single institution. Retrospective study.
Ethics committee approval: IRB approval was provided.
Funding: No funding was received for this work.

RPS 1401-7 11:51

The diagnostic performance of LI-RADS v2018 and the value of major features and ancillary features in the diagnosis of 10-19 mm hepatocellular carcinoma (HCC) on gadoxetatic acid MRI

S. Xie, J. Chen, Y. Zhang, D. Rong, L. Sun, J. Wang; Guangzhou/CN (xiesidong2001@163.com)

Purpose: Recent updates in LI-RADS v2018 have changed diagnostic criteria for 10-19 mm HCC, but few studies investigated the diagnostic performance of LI-RADS v2018 for small HCC using gadoxetatic acid MRI. We retrospectively assessed the diagnostic performance of LI-RADS v2018 for 10-19 mm HCC in Chinese patients with chronic liver disease and explored several modifications of LI-RADS aiming to improve the sensitivity for diagnosing HCC without decreasing specificity on gadoxetatic acid MRI.
Methods and materials: Between June 2015 and April 2017, 111 patients at high risk for HCC who had up to 10-19 mm observations detected on gadoxetatic acid MRI and had no history of previous treatment for hepatic lesions were retrospectively studied. LI-RADS MRI features were reviewed by two independent radiologists in consensus. Observations were categorised according to LI-RADS v2018 and several modified versions of LI-RADS, which allow major features and ancillary features favoring HCC (AFs-HCC) to upgrade LR-4 to LR-5. Sensitivities, specificities, and accuracies of LR-5 for HCC were determined and compared.
Results: A total of 129 observations in 111 patients were included, which were 86 (66.7%) HCCs, 40 (31.0%) benign lesions, and 3 (2.3%) non-HCC malignancies (Table 3). The diagnostic performance of LR-5 defined by LI-RADS v2018 for 10-19 mm HCC was modest with a sensitivity, specificity, and accuracy of 58.6%, 97.6%, and 71.3%, respectively. Comparing to LI-RADS v2018, mLI-RADS IV (APHE+HBP hypointensity[no "washout"]=LR-5) and mLI-RADS III (APHE+TP hypointensity[no "washout"] =LR-5) showed highest sensitivities (77.0%, 73.6%) ($P<0.001$, $P<0.001$) and accuracies (82.2%, 81.4%) ($P<0.001$, $P=0.001$) while maintaining high specificities (92.9%, 97.6%) ($P=1.000$, $P=0.500$) (Table 6) (Figure 1).
Conclusion: In our study we found that comparing to LI-RADS v2018, mLI-RADS IV, and mLI-RADS III improved sensitivity without decreasing specificity of LR-5 for small HCC.
Limitations: Our study has several limitations. First, we conducted our study retrospectively at a since centre, thus confirmation is warranted in a prospective multicentre setting. Second, the number of patients in our study was relatively small. Further studies with a large patient population are needed to validate the presented result in our study. Finally, the reference standard for the final diagnosis was composite and not based on a histologic diagnosis alone. This may have caused selection bias.

Ethics committee approval: IBR approval was obtained.
Funding: This work was funded.

Diagnostic accuracy of single-phase CT texture analysis for prediction of LI-RADS v2018 category

S. Puttagunta, C. van der Pol, A. M. Kulkarni, I. Carrión Martinez, J. Wat, M. Ferri*; Hamilton/CA (drputtaguntamyhead@gmail.com)*

Purpose: To determine if texture analysis (TA) can classify liver observations likely to be hepatocellular carcinoma (HCC) based on the liver imaging reporting and data system (LI-RADS) using single portal-venous phase (PVP) CT.
Methods and materials: This retrospective cohort study included 64 consecutive LI-RADS observations, 38 LI-RADS 5, 12 LI-RADS 4, and 14 LI-RAD 3, on CT over a 19-month period. Each observation was segmented on PVP images and TA features including mean Hounsfield Unit (HU), median, minimum, maximum, standard deviation, skewness, kurtosis, and entropy were extracted. The final LI-RADS category was established by two fellowship-trained abdominal radiologists on multiphase CT. PVP TA features for LI-RADS observations were compared using Kruskal-Wallis and two sample t tests. Logistic regression was used for prediction of LI-RADS group. Diagnostic accuracy was assessed using receiver operating characteristic curves and Youden's method. P<0.05 defined statistical significance.
Results: Multiple PVP TA features were associated with the LI-RADS group including the mean HU (P=0.003), median (P=0.002), minimum (P=0.010), maximum (P=0.013), standard deviation (P=0.009), skewness (P=0.007), and entropy (P<0.001). On logistic regression, skewness remained significant (P=0.016) and could predict LI-RADS group with an area-under-the-curve (AUC)/sensitivity (SN)/specificity (SP) of 0.78/70%/79%. When the logistic regression model incorporated all significant features on univariate analysis, the AUC/SN/SP improved to 0.98/96%/100%.
Conclusion: TA features on PVP CT can differentiate liver observations likely and unlikely to be HCC based on LI-RADS with high diagnostic accuracy. This may preclude the need to immediately recall some patients for additional multiphase imaging.
Limitations: Retrospective design. Sample size. 2D TA was performed and 3D TA may have provided more data.
Ethics committee approval: Research Ethics Board approved.
Funding: No funding was received for this work.

Comparison of current guidelines for the noninvasive diagnosis of hepatocellular carcinoma using gadoxetic acid-enhanced MRI: diagnostic performances in liver transplantation candidates

S. Jeon, J. M. Lee, I. Joo, J. Y. Park, J. Yoo*; Seoul/KR*

Purpose: To compare the diagnostic performances of current guidelines for diagnosis of HCC in liver transplantation (LT) candidates using gadoxetic acid-enhanced liver MRI (Gd-EOB-MRI).
Methods and materials: In this retrospective study, 81 patients (119 HCCs and 35 non-HCCs) with liver cirrhosis who underwent preoperative Gd-EOB-MRI and subsequent LT were included. Per-lesion imaging diagnoses of HCCs were made using four different guidelines (American Association for the Study of Liver Disease (AASLD), European Association for the Study of the Liver (EASL), Asian Pacific Association for the Study of the Liver (APASL), and Korean Liver Cancer Association-National Cancer Center (KLCA-NCC) guidelines), and patient allocation was determined according to the Milan criteria (MC). Comparisons of per-lesion sensitivity, specificity, and accuracy of patient allocation between guidelines were performed using logistic regression with generalised estimating equations.
Results: For diagnosis of HCC, AASLD guidelines showed the highest specificity (97.4%) followed by EASL and KLCA-NCC guidelines (92.1% and 92.1%, P>0.99 and =0.15, respectively, in comparison to AASLD), while the specificity of APASL guidelines was demonstrated to be significantly lower than that of AASLD guidelines (78.9% vs. 97.4%, P=0.006). APASL and KLCA-NCC guidelines (75.9% and 65.6%) showed significantly higher sensitivities than AASLD/EASL (34.5% and 38.8%, respectively; all Ps<0.001). For organ allocation, KLCA-NCC showed higher accuracy in selecting unsuitable candidates (with non-HCC malignancies or beyond MC HCCs) than EASL (68.4% vs. 31.8%; P=0.001).
Conclusion: For diagnosis of HCCs using Gd-EOB-MRI in LT candidates, AASLD guidelines provided the highest specificity, followed by EASL, KLCA-NCC, and APASL guidelines, with a statistically significant difference found only with APASL guidelines. KLCA-NCC guidelines provided the most accurate selection of unsuitable LT candidates.
Limitations: Retrospective design.
Ethics committee approval: Approved by IRB with a waiver of informed consent.
Funding: No funding was received for this work.

RPS 1401-12 12:09

Long-term evolution of LR-2, LR-3, and LR-4 observations in cirrhotic patients with hepatitis C treated with direct-acting antivirals

R. Cannella, S. Greco, F. Vernuccio, G. Cabibbo, C. Cammà, V. Di Marco, M. Midiri, G. Brancatelli*; Palermo/IT (rob.cannella89@gmail.com)*

Purpose: To assess the long-term evolution of observations with low (LR-2), intermediate (LR-3), and high (LR-4) probability for hepatocellular carcinoma (HCC) in cirrhotic patients with hepatitis C treated with direct-acting antivirals (DAA).
Methods and materials: This retrospective study assessed 2017 consecutive HCV patients treated with DAA between 2015 and 2019. Inclusion criteria were: i) cirrhosis or prior history of HCC, ii) available contrast-enhanced liver imaging studies (CT or MRI), iii) multiple follow-ups before and after DAA, and iv) at least one indeterminate lesion before DAA. Two radiologists reviewed imaging studies, recorded major imaging features, and categorised each lesion according to the LI-RADSv2018. Differences in evolution before and after DAA were evaluated using the Pearson $\chi 2$ or Fisher exact test. The cumulative risk of LR-5 was calculated by using the Kaplan-Meier method.
Results: Final population included 67 patients (mean age 69.5±10.8 years) with 109 observations (mean size 11.8±6.7 mm), including 31 (28.4%) LR-2, 67 (61.5%) LR-3, and 11 (10.1%) LR-4, with a mean follow-up of 44±23 months. Evolution of indeterminate observations to LR-5 was more common before DAA than after DAA (before DAA: 0 (0%) LR-2, 11 (16.4%) LR-3, and 8 (72.7%) LR-4 evolved to LR-5 vs. after DAA: 1 (3.2%) LR-2, 10 (14.9%) LR-3, and 1 (9.1%) LR-4 evolved to LR-5; p<0.001). Cumulative risk for LR-5 evolution was 15.5% at 6 months, 23.8% at one year, and 37.6% at two years. LI-RADS category was significantly associated with risk of progression into LR-5 (p<0.001).
Conclusion: The use of DAA therapy does not increase progression of indeterminate lesions into definitively HCC.
Limitations: Retrospective, small sample, lack of cohort of HCV cirrhotic patients not treated with DAA.
Ethics committee approval: IRB-approved study, informed consent was waived.
Funding: No funding was received for this work.

Evaluation of the diagnostic accuracy of the RA magnetic resonance imaging (MRI) scoring system (RAMRIS) in wrist and metacarpophalangeal (MCP) joints in patients with rheumatoid arthritis (RA)

H. Wu, G. Zhang*; Guangzhou/CN*

Purpose: To validate the relationship of the RA MRI scoring system (RAMRIS) and the Sharp/Van der Heijde score on radiography with 28-joint count disease activity score (DAS28) in therapy-naive patients with RA.
Methods and materials: We analysed radiograph and MRI data of unilateral wrist and metacarpophalangeal (MCP) joints in 408 patients with newly diagnosed rheumatoid arthritis. Two readers scored synovitis, bone marrow oedema, bone erosion, joint space narrowing, and tenosynovitis according to RAMRIS. Radiographs were scored according to the SvH method. Correlations between RAMRIS, SvH scores, and DAS28 were determined. Low to moderate (≤5.1) and high (>5.1) disease activity were divided. The differences of RAMRIS and SvH scores in the 2 groups were compared.
Results: Synovitis, tenosynovitis, and MCP (2-5) scores were positively associated with DAS28 (all p<0.05). The tenosynovitis and MCP (2-5) scores of the low to moderate disease activity groups (7.93 ± 3.97, 11.21 ± 5.3, respectively) were significantly lower than those of the high disease activity group (10.11± 4.47, 13.97 ± 5.25, respectively) (P=0.021 and P=0.025, respectively). The total scores of RAMRIS in the high disease activity group (39.19 ± 18.24) were significantly different from those of the low to moderate disease activity groups (32.48 ± 20.52, P=0.025)
Conclusion: Synovitis, tenosynovitis, and MCP scores can be used to assess the activity of RA. The tenosynovitis, MCP, and total scores of RAMRIS may be helpful for differentiating high, moderate, and low disease activity.
Limitations: The study only included inpatients and may not be entirely generalisable to other populations. This study was also limited in the evaluation of DAS-28.
Ethics committee approval: Our study was approved by the ethics committee of our hospital and informed consent was obtained.
Funding: No funding was received for this work.

RPS 1410a-2 11:21

High-resolution MRI assessment of flexor tendon pulleys in psoriatic arthritis for disease detection and differentiation from rheumatoid arthritis using a 16-channel hand coil

D. B. Abrar[1], M. Frenken[1], M. Boschheidgen[1], S. Nebelung[2], P. Sewerin[1], G. Antoch[1], D. McGonagle[3], C. Schleich[1]; *[1]Düsseldorf/DE, [2]Aachen/DE, [3]Leeds/UK*

Purpose: To evaluate the value of 3-Tesla magnetic resonance imaging (MRI) changes of flexor tendon pulleys for the differentiation of psoriatic (PsA) and rheumatoid arthritis (RA) using a novel 16-channel high-resolution hand coil.
Methods and materials: 17 patients with active PsA, 20 patients with active RA, and 16 healthy controls (HC) were evaluated by high-resolution 3T MRI using the dedicated 16-channel hand coil. Images were analysed by 3 independent readers for the degree of inflammatory changes, the thickness of flexor tendon pulleys, and the comparison to the outcome measures for RA clinical trials PsA MRI score (PsAMRIS) and to its sub-scores: synovitis, flexor tenosynovitis, bone oedema, bone erosion, periarticular inflammation, and bone proliferation.
Results: Flexor tendon pulleys were thicker in PsA than in RA patients (mean difference 0.16 mm, p<0.001) and HC (mean difference 0.2 mm, p<0.001) and showed a higher degree of associated inflammatory changes (mean difference from RA: 4.7, p=0.048; mean difference HC: 14.65, p<0.001). Additionally, there was a strong correlation of accessory pulley inflammation and total PsAMRIS and its acute-inflammatory sub-scores (for second digit: synovitis r=0.72, flexor tenosynovitis r=0.7, overall PsAMRIS r=0.72, p<0.05). Similar correlations between MRI determined pulley inflammation and synovitis, flexor tenosynovitis, and periarticular inflammation were evident in digits 3-5. Weaker correlations between pulley inflammation and PsAMRIS and its inflammatory subscores were evident in RA.
Conclusion: The assessment of MRI changes of flexor tendon pulleys is potentially beneficial for disease detection in PsA, as well as for its distinction from RA and HC.
Limitations: A small study population and a different disease duration of the study groups.
Ethics committee approval: Study was approved by the local ethics comittee.

The semi-automated algorithm for the detection of bone marrow oedema lesions in patients with axial spondyloarthritis

I. Kucybała, J. Polak, Z. Tabor, A. Urbanik, W. Wojciechowski*; Cracow/PL (iwona.kucybala@gmail.com)*

Purpose: To create an efficient tool for the semi-automated detection of bone marrow oedema lesions in patients with axial spondyloarthritis (axSpA).
Methods and materials: MRI examinations of 22 sacroiliac joints of patients with confirmed axSpA-related sacroiliitis (mean SPARCC score: 24.3±26.1) were included in the study. The design of our algorithm is based on Maksymowych et al. evaluation method and consists of the following steps: manual segmentation of bones (T1W sequence), automated detection of reference signal region, sacroiliac joint central lines and ROIs, a division of ROIs into quadrants, and automated detection of inflammatory changes (STIR sequence). As a gold standard, two sets of manual lesion delineations were created. Two approaches to the performance assessment of lesion detection were considered: pixel-wise (detections compared pixel by pixel) and quadrant-wise (quadrant to quadrant). Statistical analysis was performed using Spearman's correlation coefficient.
Results: The correlation coefficient obtained for pixel-wise comparison of semi-automated and manual detections was 0.87 (p=0.001, 95% CI 0.83-0.92), while for quadrant-wise analysis was 0.83 (p=0.001, 95% CI 0.75-0.89). The correlation between two sets of manual detections was 0.91 for pixel-wise comparison (p=0.001, 95% CI 0.86-0.94) and 0.88 (p=0.001, 95% CI 0.82-0.92) for the quadrant-wise approach. Spearman's correlation between two manual assessments was not statistically different from the correlation between semi-automated and manual evaluations, both for pixel- (p=0.14) and quadrant-wise (p=0.17) analysis. The average single-slice processing time was 0.64±0.30 seconds.
Conclusion: Our method allows for highly objective detection of bone marrow oedema lesions in patients with axSpA. The quantification of both affected pixels and quadrants using our semi-automated algorithm have comparable reliability to manual assessment.
Limitations: Time-consuming manual segmentation of bones.
Ethics committee approval: Jagiellonian University Bioethics Comittee approval No.1072.6120.16.2019.

How tin filtration affects the value of an effective radiation dose in CT of the sacroiliac joints: can CT replace x-ray in patients with suspected sacroiliitis?

E. Korcakova, J. Štěpánková, D. Suchy, P. Hosek, K. Bajcurova, J. Pernicky, H. Mirka*; Plzen/CZ (korcakovae@fnplzen.cz)*

Purpose: To calculate values of an effective radiation dose given by tin-filtrated ultra-low dose computed tomography (TFULDCT) in a cohort of patients referred with suspected sacroiliitis. For comparison, the effective radiation doses given by x-ray in the same group were calculated. We evaluated the accuracy of TFULDCT and x-ray for detecting bone changes in sacroiliac joints (SI).
Methods and materials: Effective radiation dose was calculated by an experienced radiation physicist using ImpactDose 2.3, patient model-real patient data (CT Imaging GmbH, Germany), and PCXMC 2.0 (x-ray, STUK Finland). Datasets of 30 consecutive patients examined by TFULDCT and x-ray were

evaluated independently by 3 radiologists. Every investigator blindly evaluated the CT and x-ray studies and decided whether the finding was positive, negative, or uncertain for sacroiliitis. The results were statistically evaluated.
Results: The median value of an effective radiation dose received by TFULDCT of SI joints in our cohort was 0.11 mSv (0.06-0.34 mSv). The median of an effective radiation dose for x-ray in the same patient cohort was 0.22 mSv (0.09-0.58 mSv). CT provides a statistically significantly more reliable distinction between positive and negative cases than x-ray. X-ray had a greater number of unclear findings.
Conclusion: Our results show that TFULDCT significantly reduces the effective radiation dose and in the examination of SI joints achieves lower values than an x-ray. TFULDCT can be used for monitoring patients with axial spondylartitis because it has a high accurancy in assessing the bone changes and does not burden patients with a high radiation dose.

Glycosaminoglycan remodelling of lumbar intervertebral discs in elite rowers throughout their annual training cycle
M. Frenken, L. Kasprowski, M. Boschheidgen, B. Bittersohl, G. Antoch, C. Schleich, S. Nebelung, D. B. Abrar*; Düsseldorf/DE (miriam.frenken@med.uni-duesseldorf.de)*

Purpose: To assess the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in elite rowers (ER) at different stages of their annual training cycle compared to healthy volunteers (HV) using GAG chemical exchange saturation transfer (gagCEST).
Methods and materials: 205 lumbar IVD of 21 ER (23 ±3 years, 9 female, 11 male) and 25 HV (27 ±2 years, 13 female, 12 male) were prospectively examined with 3T magnetic resonance imaging (MRI). Standard T2-weighted (T2w) sequences were used for morphological grading according to the Pfirrmann classification. GAG content of the nucleus pulposus (NP) and annulus fibrosus was determined with gagCEST in non-degenerated discs according to Pfirrmann. ER were examined during the peak of their competition preparation (T0) and 6 months later during the peak of their post-competition recovery period (T1).
Results: At T0 we found significantly higher gagCEST values in ER compared to HV (NP: 4.26 ±2.37% vs 3.38 ±1.72%, p<0.05; confidence interval (CI) 0.32%/1.44%; AF: 2.75 ±1.7% vs 1.961 ±1.23%, p<0.01; CI 0.4%/1.2%). At T1, gagCEST values decreased and illustrated no significant difference compared to HV (NP: 3.55 ± 2.31%, p=0.531, CI 0.038%/0.73%; AF: 2.31 ±1.57%, p=0.073, CI 0.03%/0.74%).
Conclusion: Compared to HV, lumbar IVD of ER show significantly higher gagCEST values during the peak of their competition preparation and similar values during the recovery period, indicating a GAG remodelling effect by training. The results suggest that physical activity (rowing) potentially prevents molecular GAG depletion in the lumbar IVD.
Limitations: Observations over a one-year training cycle, no long-term results beyond that.

Degeneration at atypical spinal segments in patients with abdominal aortic aneurysms
N. A. Farshad-Amacker, M. Farshad, J. Galley, R. Sutter, T. Götschi, U. J. Mühlematter*; Zurich/CH (nadja.farshad@balgrist.ch)*

Purpose: Abdominal aortic aneurysms (AAA) affect vascular perfusion of the lumbar spine by compromising its direct vascular supply. AAA treatment with endovascular aortic aneurysm repair (EVAR) completely occludes the direct vascular supply to the lumbar spine. We hypothesised that patients with AAA and patients with EVAR show a different pattern of spinal degeneration compared to controls without AAA.
Methods and materials: Patients who underwent EVAR with computed tomography images (CT) >6 months prior (n=52), at the time of EVAR (n=100), and >1 year after EVAR (n=100) were included and compared to an age- and gender-matched control group without AAA (n=94). Degeneration scores, levels with the most severe degeneration, and levels with the progression of degeneration were analysed in CT and compared at different time points. Statistics included Fisher's exact test, Wilcoxon's signed-rank test and a Mann-Whitney U test.
Results: Levels of most severe degeneration were located more commonly in the mid-lumbar area in AAA patients compared to control subjects (p=0.016) with significantly more endplate erosions (p=0.001). However, EVAR did not result in an additional accelerated degeneration.
Conclusion: AAA is associated with atypical location of lumbar spinal degeneration at the mid-lumbar segments, but EVAR does not seem to additionally accelerate the degenerative process. This observation underlines the importance of disc and endplate vascularisation in the process of spinal degeneration.
Limitations: The retrospective design.
Ethics committee approval: The ethical committee approved this retrospective study.
Funding: No funding was received for this work.

Ultrasound evaluation of nail and extensor digitorum tendon involvement in psoriatic patients
L. Wang, L. Qiu*; Chengdu/CN (liyunwang1992@qq.com)*

Purpose: To evaluate ultrasound manifestations of the nail involvement in psoriatic patients, compare them with healthy individuals, and search for correlations between ultrasonography and clinical features.
Methods and materials: 37 psoriatic patients and 42 healthy volunteers were included. PASI index, mNAPSI index, and psoriatic area were recorded of all patients. 6 ultrasonography parameters in B mode and power Doppler concerning the nail plate, the bed, the matrix, the proximal nail fold, and extensor digitorum tendon of each finger in all subjects were evaluated and compared.
Results: The incidence of US abnormal morphology in the nail plate was significantly higher in psoriatic patients than healthy controls (55.98% vs 4.05%). The nail plate, the bed, the matrix, the proximal nail fold, and the extensor digitorum tendon were significantly thicker in psoriatic patients (0.82±0.25 vs 0.66± 0.09mm, 1.78±0.63 vs 1.48±0.33 mm, 2.81±0.51 vs 2.55±0.46 mm, 0.96±0.23 vs 0.89±0.13 mm, and 1.07±0.38 vs 1.00±0.29 mm, $p < 0.05$, respectively). The largest area under the curve (AUC) was obtained from the nail plate (AUC=0.749). No statistical difference was found in power Doppler ultrasound grading between both groups. The thicknesses of the nail plate, the bed, and the matrix were positively correlated with PASI index, mNAPSI index, and psoriasis area.
Conclusion: The changes of the nail unit and extensor digitorum tendon can frequently be found by ultrasound in psoriatic patients. Special attention might be paid to the ultrasonographic morphology and thickness of the nail plate.
Limitations: We did not evaluate nails with other imaging methods.
Ethics committee approval: The Clinical Trials and Biomedicine Ethics Committee of West China Hospital of Sichuan University approved this study and informed consent was obtained.
Funding: The National Natural Science Foundation of China (81671696).

RPS 1410a-8 11:57
The role of ultrasonography in monitoring long-standing rheumatoid arthritis
M. L. Dura, P. Zuchowski, P. Gorgolewski, S. Jeka*; Bydgoszcz/PL (p.zuchowski81@gmail.com)*

Purpose: In the course of rheumatoid arthritis (RA) there may occur irreversible inflammatory-destructive changes within joints. In later stages of RA, joint pain often results from destructive changes instead of an active inflammatory process in the synovial membrane. The aim of this study was to assess the cause of joint

pain in patients with long-standing RA (LSRA) in whom low disease activity was diagnosed through a disease activity score (DAS28).
Methods and materials: 53 patients with RA were enrolled in the study, each with low disease activity (DAS28 (CRP) <3.2) and disease history of 8 years or more. Participants had their metacarpophalangeal (MCP) II-V and proximal interphalangeal (PIP) I-V joints evaluated through physical examination. Joints exhibiting pain were further subjected to power Doppler ultrasound (PDUS) and grey-scale ultrasound (GSUS) examination.
Results: 954 joints in total were evaluated through physical examination, with pain found in 218 (22%) joints in 41 (77%) patients. In 218 joints examined through PDUS, an active inflammatory process was found in 171 (78%) joints. In the remaining 47 (22%) joints, the pain was related to irreversible destructive changes, including the presence of bone erosion in radiographs and membrane hypertrophy determined via GSUS. In the group of 41 patients with joint pain determined through physical examination, in 6 (15%) it was related to the presence of irreversible destructive changes and not an active inflammatory process.
Conclusion: US examination allows the designating of patients with LSRA in whom joint pain is connected with irreversible destructive changes in joints. In such a patient group, it may be advisable to terminate or alter the standard therapy for patients with active RA.
Limitations: A small study group.
Ethics committee approval: n/a

RPS 1410a-9 12:03

The importance of lumbrical muscle enhancement on bilateral dynamic contrast-enhanced hand MRIs of patients with arthralgia: a possible diagnostic MRI-clue for rheumatoid arthritis

Z. Akkaya, A. Gürsoy Çoruh, A. H. Elhan, G. Sahin*; Ankara/TR (zehraakkaya@gmail.com)*

Purpose: To investigate the significance of lumbrical muscle enhancement (LME) in patients with hand arthralgia.
Methods and materials: Blinded to the diagnoses, dynamic contrast-enhanced bilateral hand MRIs of 100 patients (F:M=88:12) with hand arthralgia taken from 2014-2019, using 3.0T and 1.5T scanners, were retrospectively evaluated by 2 radiologists for the presence of LME. When identified, the degree of enhancement was graded as weak or strong.
Patients were stratified in 3 groups according to their final diagnoses as rheumatoid arthritis (RA)(n=41), control (fibromyalgia, osteoarthritis(OA), and rheumatological disease-ruled out cases)(n=31), and other arthritides groups (n=28)(spondyloarthropathy, Behçet's, Sjögren's, erosive OA, systemic lupus erythematosus, dermatomyositis, and polymyalgia rheumatica).
Categorical variables were compared by using Chi-Square/Fisher's exact tests. The difference among groups for continuous variables was evaluated by one-way ANOVA/Kruskal Wallis ANOVA. A multiple comparison test was used to know which groups differed from others where applicable. The agreement between raters was assessed by Cohen's Kappa(κ) statistic. P values <0.05 were considered significant.
Results: The mean patient age was 47.2±11.2. Age and gender were not significantly different among groups (p=0.17, p= 0.84, respectively). The RA group showed significantly more (p<0.001) and a stronger degree of enhancement (p=0.001) with substantial inter-rater-correlations for right and left hands (κ=0.739, κ=0.671, respectively, p<0.001). Right hands of RA and control patients showed significantly more LME (p=0.001, p=0.033, respectively).
Conclusion: In comparison to controls and other arthritides cases, RA patients demonstrated a significantly higher rate and degree of LME on MRIs with substantial inter-rater-correlations. This could indicate a subtle but important radiological clue for the diagnosis and differential diagnosis of RA.
Limitations: Due to the difficulty in recruiting patients with definitely established diagnoses, patient numbers were low in the arthritides group for individual disease analyses.
Ethics committee approval: Hospital Ethics Review Board approval was obtained.
Funding: No funding was received for this work.

RPS 1410a-10 12:09

T2 mapping of the sacroiliac joints in patients with axial spondyloarthritis: a pilot study

D. Albano[1], R. Bignone[2], V. Chianca[1], R. Cuocolo[3], C. Messina[1], L. M. M. Sconfienza[1], F. Ciccia[2], M. Midiri[2], M. Galia[2]; [1]*Milan/IT,* [2]*Palermo/IT,* [3]*Naples/IT (albanodomenico@me.com)*

Purpose: To determine whether T2-mapping of the sacroiliac joints (SIJs) might help to identify patients with spondyloarthritis.
Methods and materials: This pilot study included 21 biologic-naive patients with axial spondyloarthritis (10 males; mean age=43±12years; range=19-57) and 21 controls (14 males; mean age=34±10; range=28-71) who prospectively underwent SIJs MRI at 1.5T, including a multislice multi-echo spin-echo sequence. Standard MRIs were reviewed to assess the SIJs according to the assessment of spondyloarthritis international society (ASAS) criteria and spondyloarthritis research consortium of Canada (SPARCC) MRI index. T2 maps were used to draw regions of interests in the cartilaginous part of the SIJs. Disease activity was assessed using a BASDAI questionnaire. The Bland-Altman method, ROC curve analysis, Chi-square, Mann-Whitney U, Pearson's and Spearman's correlation coefficient were used for data analysis.
Results: MRI was positive for sacroiliitis in 6/21 patients (29%). Interobserver reproducibility of T2 values was 88% (coefficient of repeatability=5.9, bias=0.96, p<0.001). Mean T2 values of patients (59.2±2.9ms, range: 54.3-66.3ms) were significantly higher (p<0.001) than those of controls (39.6±3.4ms, range: 33.6-46.6ms). A T2 value of 50.5ms yielded 100% sensitivity and 100% specificity to differentiate patients from controls. Mean T2 values on the iliac side of the SIJs of patients (62.8±9.8 ms) were significantly higher than on the sacral side (56.4±11.3 ms; p<0.001). No significant association/correlation was found between T2 values and BASDAI, disease duration, SPARCC, ASAS criteria, HLA-B27-positivity, age, and gender (p≥0.197).
Conclusion: T2 values of the SIJs were significantly higher in patients than in healthy controls, making this tool potentially helpful for early identification of patients with spondyloarthritis.
Limitations: A small sample size and a lack of follow-up.
Ethics committee approval: IRB approval was obtained. All patients provided their written informed consent.
Funding: No funding was received for this work.

Loss of glycosaminoglycans in lumbar intervertebral discs in patients with ankylosing spondylitis

D. B. Abrar[1], M. Frenken[1], M. Boschheidgen[1], S. Nebelung[2], G. Antoch[1], P. Sewerin[1], X. Baraliakos[3], C. Schleich[1]; [1]*Düsseldorf/DE,* [2]*Aachen/DE,* [3]*Herne/DE*

Purpose: To evaluate the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in patients with ankylosing spondylitis (AS) using GAG chemical exchange saturation transfer (gagCEST).
Methods and materials: 325 lumbar IVD of 40 patients with AS (mean age 50 ±10 years) and 25 healthy control patients (HC) were prospectively examined with 3T magnetic resonance imaging (MRI). MRI protocol contained morphological T2-weighted (T2w) images to grade IVD according to the Pfirrmann classification and biochemical imaging with gagCEST to calculate a region of interest (ROI) of the nucleus pulposus (NP) and annulus fibrosus (AF). Prior to the statistical testing of gagCEST effects in patients and HC, IVD were classified according to Pfirrmann.
Results: Significantly lower gagCEST values of NP and AF were found in non-degenerative IVD (Pfirrmann 1 and 2) of AS patients compared to HC (NP: 1.88 % ±1.21% vs 3.38 % ±1.71%; p<0.01; confidence interval (CI): 0.89%/2.11%. AF: 1.11 % ± 1.07 % vs 1.96 %± 1.23 %; p<0.01; CI 0.39%/1.3%).
Conclusion: GagCEST analysis of morphologically non-degenerative IVDs in T2w images showed significantly lower GAG values in patients with AS in the NP and AF compared to HC.
Limitations: A small study population and differences in disease duration and treatment.
Ethics committee approval: Written and inforfmed consent. Approval by the local ethics committee.
Funding: No funding was received for this work.

Reduction of metal artefacts caused by titanium peduncular screws at the spine using monoenergetic images and the MARS (metal artefact reduction software) system in dual-energy computed tomography
L. Ceccarelli, F. Ponti, P. Spinnato, R. Clinca, L. Lotrecchiano, A. M. Chiesa, G. Facchini*; Bologna/IT*

Purpose: To evaluate the reduction of metal artefacts in patients with titanium peduncular screws at spine level using standard acquisitions, monoenergetic images (mono-E), and monoenergetic image + MARS (mono-E+MARS) acquired with dual-energy computed tomography (CT).
Methods and materials: 25 patients (15 women, 10 men) who had undergone vertebral stabilisation with titanium peduncular screws were studied using dual-energy CT (GE, Discovery 750 HD) with standard acquisitions (QC), 100 to 140 keV monoenergetic reconstructions and 140keV+MARS reconstruction.
A quantitative evaluation was performed using ROI to measure attenuation (Hounsfield Unit (HU)) at the most hyperdense and most hypodense artefacts caused by titanium peduncular screws.
A qualitative analysis was also performed based on subjective evaluation by two radiologists in terms of image quality and the reduction of artefacts.
Results: A comparison of the mean attenuation values showed a significant ($p<0.0001$) reduction of artefacts in 140keV+MARS images compared to monoenergetic and conventional images at the level of the most hyperdense and hypodense artefacts.
Monoenergetic reconstructions showed a significant ($p<0.0001$) reduction of artefact compared to conventional images.
Monoenergetic images were qualitatively richer in diagnostic information.
Conclusion: Mono-E+MARS showed a quantitatively greater reduction of artefacts from titanium peduncular screws at spine level, although monoenergetic images were better from a diagnostic point of view.
Limitations: The retrospective nature of the study.
Ethics committee approval: We obtained ethics committee approval.
Funding: No funding was received for this work.

Exposure to environmental tobacco smoke estimated using the SHSES scale and epicardial adipose tissue thickness in patients with hypertension
P. Gac, M. Poreba, P. Macek, G. Mazur, R. Poreba*; Wroclaw/PL (pawelgac@interia.pl)*

Purpose: To assess the relationship between the exposure to environmental tobacco smoke (ETS) estimated using the SHSES scale and epicardial adipose tissue thickness (EATT) in patients with hypertension.
Methods and materials: The study included 96 people with hypertension (69.32±9.54 years). All patients were assessed for exposure to ETS based on the SHSES scale and 128-slice coronary computed tomography (coroCT) was performed. Based on the SHSES scoring criterion, subgroups of subjects were identified: A) without ETS exposure (0 SHSES points, n=50), B) low ETS exposure (1-3 SHSES points, n=11), C) moderate ETS exposure (4-7 SHSES points, n=20), and D) high ETS exposure (8-11 SHSES points, n=17). Based on the images obtained in coroCT, EATT was measured. The maximum measurement taken along the anterior free wall of the right ventricle was taken as EATT.
Results: In the studied group, EATT was 5.75±1.85 mm. EATT was statistically significantly higher in subgroup D than in subgroups A and B (A: 5.28±1.64 mm, B: 5.04±2.64 mm, D: 7.04±2.64 mm, p_{A-D} and $p_{B-D}<0.05$). There was a positive linear correlation between exposure to ETS expressed by the number of points on the SHSES scale and EATT ($r=0.44$, $p<0.05$). In the regression analysis, it has been documented that higher SHSES scores, higher BMI, and higher systolic and diastolic blood pressure values are independent risk factors for higher EATT, while the use of ACE inhibitors and β-blockers are independent protection factors against higher EATT.
Conclusion: In patients with hypertension, there is a positive relationship between exposure to environmental tobacco smoke estimated using the SHSES scale and epicardial adipose tissue thickness.
Limitations: A single-centre study.
Ethics committee approval: Local Bioethical Committee.

Principal shape components derived from shape analysis of left coronary artery bifurcation correlated weakly with calcium score in a cohort with intermediate cardiovascular risk
Y. Huang, W.-J. Lee, S.-J. Chen, Y.-C. Chen, C.-L. Ko, T.-D. Wang, C.-M. Chen, Y.-C. Chang*; Taipei/TW (squll1peter@gmail.com)*

Purpose: A wide left coronary artery bifurcation angle has been reported to be associated with the severity of coronary artery disease, but it may not reflect complex three-dimensional vessel morphology. This study aimed to utilise statistical shape analysis to categorise and quantify the shape patterns of left coronary artery bifurcation, and correlate the shape changes to coronary calcium scores.
Methods and materials: Coronary CT angiography obtained from 406 subjects with intermediate cardiovascular risks were retrieved from a cross-modality multicentre cardiovascular imaging database. The centrelines of the left coronary artery adjacent to bifurcation was extracted and manually corrected. Statistical shape analysis of these centerlines was performed and the most significant principal components were determined by a scree test. The correlations between shape quantification results and coronary calcium scores were examined with the Pearson correlation coefficient. Patients were stratified into a high-calcium score group (Agatston score>100) and a low calcium score group.
Results: The scree test yielded 5 most significant shape patterns, explaining 76% of changes. The derived principal components were used on 178 subjects with available clinical information. There was a weak correlation: the calcium scores of LAD and LCX increased with wider bifurcating angle and shorter LM length (PC#1) (Pearson correlation coefficient: 0.18 for LM and 0.17 for LCx). The calcium score was independent of a simple acute turn at proximal LCX (PC#3). The differences in shape patterns were not significant between the high-calcium score group and the low-calcium score group.
Conclusion: Statistical shape analysis provided comprehensive shape change pattern observation. The calcium score of the left coronary artery was weakly correlated with LM length and bifurcating angle, and was independent of simple acute proximal turn of LCX.
Limitations: Shape analysis is subjected to intepretation.
Ethics committee approval: Aproved by NTUH research ethic committee.

Coronary artery calcification with high-pitch chest CT using 256-detector row wide-volume CT scanner: comparison with dedicated calcium scoring CT

J. M. Shin, T. H. Kim, S. Y. Lee, S. J. Ki, C. H. Park*; Seoul/KR (sjaemin@yuhs.ac)*

Purpose: To assess the reliability of non-gated non-contrast chest CT (NCCT) with a wide coverage and fast gantry rotation time reconstructed at different slice thicknesses in quantification of coronary artery calcification (CAC) compared to ECG-gated calcium scoring cardiac CT (CaCT).
Methods and materials: Patients aged ≥50 who clinically required NCCT were prospectively enrolled. All CT scans were performed with 256-detector rows (z-axis coverage: 16 cm) and a gantry rotation time of 280 ms. NCCT was performed and immediately followed by CaCT. NCCT images were reconstructed at 0.625, 1.25, and 2.5 mm slice intervals. The CAC score was calculated using the Agatston method and also divided into four standard categories (0, 1-100, 101-400, and >400). Interobserver and intertechnique agreements were evaluated.
Results: 26 patients (14 males, mean age=66.04±6.97 years) were enrolled. The correlation of CAC scores between CaCT and NCCT with each slice thickness was almost perfect. The mean differences between CaCT and NCCT with a slice thickness of 0.625, 1.25, and 2.5 mm were 37.54, 6.67, and -41.04, respectively, in Bland-Altman plots. Intertechnique concordance of the four Agatston scoring categories was high with linear weighted kappa values of 0.599, 0.609, and 0.597 for NCCT and with a slice thicknesses of 0.625, 1.25, and 2.5 mm, respectively.
Conclusion: CAC quantification with NCCT using wide-detector, high-pitch, and high–temporal resolution scanning modes is almost perfectly consistent with CaCT and the strongest correlation was shown at a slice thickness of 1.25 mm.
Limitations: The patient number was small for the results to be generally accepted and iterative reconstruction used in this study might influence the absolute value of the CAC scores.
Ethics committee approval: Institutional review board of Gangnam Severance Hospital approved this study and all patients gave written informed consent.
Funding: No funding was received for this work.

Altered cardiac structure and function below recent risk-thresholds: a population-based cardiac magnetic resonance study

F. C. Laqua[1], R. Bülow[1], S. Gross[1], T. Ittermann[1], H. Völzke[1], S. Felix[1], M. Dörr[1], N. Hosten[1], P. L. Madsen[2]; *[1]Greifswald/DE, [2]Copenhagen/DK*

Purpose: To determine alcohol-associated cardiac remodeling and sex-specific differences by cardiac magnetic resonance imaging (CMR) in a low-risk population-based sample.
Methods and materials: In the Study of Health in Pomerania, 1,134 voluntaries (median age 51 years, 55.7% men) underwent gadolinium-enhanced CMR between 2008 and 2012. In a cross-sectional approach, left ventricular (LV) and left atrial (LA) structure and function were related to self-reported alcohol intake over the past month in multivariable linear regression models adjusted for a priori specified clinical and socio-demographic confounders.
Results: 75% of the investigated population consumed less than recently recommended limits of 100 g/week. Only in men was alcohol intake associated with a linearly greater LV mass ($\beta_{fullmodel}$=0.140(0.049;0.23) d (95%-CI); p=0.003), cardiac output ($\beta_{fullmodel}$=0.0093(0.002;0.02) l $min^{-1}g^{-1}$ d; p=0.008), and a lower systemic vascular resistance ($\beta_{fullmodel}$=-0.020(-0.04;-0.002) mmhg l^{-1}min g^{-1}d; p=0.030). In contrast, alcohol intake was associated with greater LV wall-stress ($\beta_{fullmodel}$=1.21(0.3;2.1) mmHg g^{-1}d; p=0.008) in women only. For neither men nor women was alcohol intake related to LV end-diastolic volume, LA maximal volume, LV ejection fraction, or late gadolinium enhancement.
Conclusion: Even in a low-risk drinking population, alcohol intake for men is dose-dependently associated with peripheral vasodilation and a greater LV mass, independent from hypertension. In contrast, despite unchanged geometry, women's hearts are exposed to greater LV wall-stress. Cardiac structure and function is altered below currently recommended risk-thresholds for alcohol intake.
Limitations: The character of an observational study limits the ability to confirm causal relationships. Regression-dilution bias may arise from using alcohol consumption during the past month as a proxy for usual/cumulative consumption.
Ethics committee approval: All individuals gave written informed consent and the study was approved by Ethics Committee of the University of Greifswald.
Funding: This study is supported by the German Federal State of Mecklenburg-West-Pomerania.

Metabolic syndrome and ectopic fat deposition in subclinical type 2 diabetes mellitus as determined by 1H-Magnetic resonance spectroscopy

Y. Gao[1], Z.-G. Yang[1], R. Shi[1], L. Jiang[2]; *[1]Chengdu/CN, [2]Guangzhou/CN (304789161@qq.com)*

Purpose: The purpose of this study was to assess the effects of MetS and ectopic fat deposition on LV structure changes in subclinical type 2 diabetes mellitus (T2DM).
Methods and materials: 53 T2DM patients and 20 healthy controls were prospectively enrolled. All of them performed CMR (3.0-T, Siemens Medical Solutions, Germany). We excluded patients with known cardiovascular disease and cardiovascular-related symptoms. We divided patients into MetS group and non-MetS group. Single-voxel ^{1}H-MRSS was performed to detect the myocardial triglyceride content using the post-processing software (jMRUI, version 6.0).
Results: Myocardial TG content was significantly higher in T2DM patients compared with controls (1.54±0.63 vs. 0.61±0.22 %, p < 0.001). GLS was lower in the MetS group than the non-MetS group and normal controls (all p<0.001). The MetS group had a significantly reduced upslope value (2.10±1.19 vs. 2.93±0.78, p<0.001) and an increased TTM value (36.09±14.57 vs. 24.77±11.01, p<0.001) than the controls. A correlation existed between the myocardium TG content and GLS (r = 0.339, p <0.05) and TTM (r = 0.415, p <0.05). ROC analysis showed that 1.56 was the optimal cutoff values of myocardium TG content that predicted the risk of LV deformation (AUC=0.71).
Conclusion: T2DM patients with MetS will cause more serious damage to the myocardium and myocardial TG content is negatively correlated with LVGLS and perfusion.
Limitations: The sample size was too small. A single-centre study, therefore an inclusion bias.

Association of coffee consumption with MRI markers of cerebral small vessel disease, cardiac function, and fat depots in a population-based study cohort

E. Beller[1], R. Lorbeer[2], D. Keeser[2], F. Meinel[1], S. Grosu[2], F. Bamberg[3], C. L. Schlett[3], B. B. Ertl-Wagner[4], S. Stöcklein[2]; *[1]Rostock/DE, [2]Munich/DE, [3]Freiburg/DE, [4]Toronto, ON/CA (ebba.beller@gmail.com)*

Purpose: Coffee is one of the most popular beverages in the world and even small health effects may have a large impact on public health. Therefore, we sought to determine the relationship between coffee consumption and cerebral small vessel disease (SVD), cardiac function, or fat depots, using a whole-body magnetic resonance imaging (MRI) protocol.
Methods and materials: MRI markers of SVD, cardiac function, and fat depots were obtained in a population-based study cohort without cardiovascular disease. A blended approach was used to estimate habitual coffee consumption. Associations of coffee intake with total brain volume, white matter lesions, cerebral microbleeds, total (TAT) and visceral adipose tissue (VAT), hepatic proton density fat fraction ($PDFF_{hepatic}$), and cardiac function were assessed by linear regression.

Results: In a sample of 132 women (mean age 56.3±8.8years) and 168 men (mean age 56.2±9.3years), habitual coffee consumption was positively associated with MR-based cardiac function parameters including late diastolic filling rate, stroke volume ($p<0.01$ each), and ejection fraction ($p<0.05$) when adjusting for age, sex, smoking, hypertension, diabetes, LDL, triglycerides, cholesterol, and alcohol consumption. Coffee consumption was negatively associated with VAT when adjusting for age, sex, smoking, hypertension, diabetes, LDL, triglycerides, and cholesterol ($p<0.05$), but not after additional adjustment for alcohol consumption. There was no significant association between coffee consumption and early diastolic filling rate, end-diastolic and end-systolic volume, TAT, $PDFF_{hepatic}$, or SVD parameters.
Conclusion: We found a significant positive and independent association between coffee intake and MRI-based systolic and diastolic cardiac function. Coffee consumption also seems to be inversely associated with VAT, but not independent of alcohol consumption. A significant association between coffee consumption and SVD was not observed.
Limitations: No difference between coffee preparation method or type of coffee was made.
Ethics committee approval: Ethic committee approved.

Coronary artery calcium scoring: towards an update of the international standard
G. D. van Praagh[1], J. Wang[1], N. R. van der Werf[2], M. Greuter[3], D. Mastrodicasa[1], K. Nieman[4], D. Fleischmann[1], M. J. Willemink[1]; [1]Stanford, CA/US, [2]Utrecht/NL, [3]Groningen/NL (gijsvanpraagh@live.nl)

Purpose: Improvements of CT technology over the last decade allow for improved acquisition and reconstruction methods of coronary artery calcium (CAC) quantification. Currently, CAC-CT requires a relatively high radiation dose and inter- and intra-scan reproducibility is suboptimal. This study aimed to optimise the standard for CAC-quantification using low-kVp protocols with improved reproducibility on state-of-the-art CT systems from two major vendors.
Methods and materials: An anthropomorphic thoracic phantom with cardiac calcification insert containing 9 cylindrical calcifications and 2 additional extension rings was used. Images were acquired with new-generation CT systems from two vendors using routine protocols and a variety of tube voltages (120-80 kVp), tube currents (≤75% dose reduction), slice thicknesses (3/2.5 and 1/1.25 mm), and reconstruction techniques (filtered back projection and iterative reconstruction (IR)). Every protocol was scanned 5 times after repositioning of the phantom to asses reproducibility. Calcifications were quantified as Agatston and volume scores. Routine scores were compared to other scores using Friedman's tests and post-hoc Wilcoxon signed-rank tests with Bonferroni correction.
Results: Reducing tube potential to 100 kVp, radiation dose with 25%, and slice thickness to 1/1.25 mm, respectively, combined with high IR-levels, resulted in similar total Agatston scores ($P>0.05$). Total volume slightly reduced to values closer to the physical volume ($P>0.05$). Moreover, intrascanner CAC-score variability decreased with 1-9%. Analysis per calcification showed that variability and CAC-scores decreased in higher density calcifications. In lower density calcifications, CAC-scores increased due to increasing HU-values. On average, 6/9 lesions were detected with traditional slice thickness, while 7/9 were detected with thin-slice images.
Conclusion: This multivendor study showed protocol-optimisation resulted in reduced radiation doses without affecting total Agatston scores, volume scores closer to the physical volume, and improved reproducibility.

Increased epicardial adipose tissue accumulation as a predictor for essential hypertension in non-obese adults
A. Dobrovolskij[1], D. Austys[2], V. Jablonskienė[2], V. Dobrovolskij[2], N. Valeviciene[2], R. Stukas[2]; [1]Coblenz/DE, [2]Vilnius/LT (adobrovolskij@gmail.com)

Purpose: Essential hypertension (EH) is identified as one of the most important risk factors for cardiovascular morbidity in industrialised countries. Epicardial adipose tissue (EAT) is considered to be an important factor in the development of cardiovascular diseases. The pathophysiological mechanisms of EAT remain unclear to this day. Diverging results are presented regarding the association between EAT and EH. Moreover, there has been insufficient research on EAT association with different stages of EH. Our aim was to evaluate the association between size of EAT depots and the risk of EH, taking into account its stage.
Methods and materials: There were 258 non-obese adult patients investigated with different cardiovascular diseases, 157 of whom had EH and 101 who did not. Patients with EH were classified to 3 groups according to the stage of hypertension. Volume and thickness of EAT depots on ventricular free walls (6 locations) and grooves (5 locations) were measured using cardiac magnetic resonance tomography images, and then compared between groups. For the prediction of EH, a regression model was constructed.
Results: Overall, EAT thickness (in all locations) and volume were higher among hypertensive patients ($p<0.001$). Mean EAT thickness and volume were larger in the stage 1 hypertension group than among normotensive patients ($p<0.05$). Furthermore, the volume of EAT was lower in the stage 1 than in the stage 2 hypertension group ($p<0.05$). However, the EAT depots did not differ between severe and the estage 2 hypertension group. EAT volume, patients' age, body mass index, and dyslipidaemia status were independent with EH associated factors in a predictive model.
Conclusion: Significant differences in EAT accumulation between hypertensive and normotensive patients show that EAT measurements may serve as a risk indicator for EH as well as a predictor of hypertension severity.

Impact of blending weight in hybrid iterative reconstruction on coronary artery calcium score based on cardiac CT
Z. Liu; Beijing/CN (liuzhuormyy@sina.cn)

Purpose: To investigate the impact of blending weight in hybrid iterative reconstruction (ASIR-V) on coronary artery calcium scores and risk classification based on cardiac CT.
Methods and materials: The non-contrast ECG-gated cardiac CT images of 100 patients were reconstructed using different blending weights of ASIR-V, including FBP (0% ASIR-V), 20% ASIR-V, 40% ASIR-V, 60% ASIR-V, 80% ASIR-V, and 100% ASIR-V. The average CT value and standard deviation (SD) in the ascending aorta and the maximum value of calcified plaque were compared among the different reconstructions. Agatston score, mass score, volume score, and risk classification based on Agatston score were also compared.
Results: An increased percentage of ASIR-V was associated with a reduction in SD of ascending aorta and the 3-types of calcium scores ($P<0.05$). Agatston scores were 170.2±387.3, 168.6±385.3, 166.4±381.9, 164.6±379.4, 162.9±376.7, and 161.1±374.1 for reconstructions, with 0%, 20%, 40%, 60%, 80%, and 100% ASIR-V, respectively. Mass scores were 23.62±52.56, 23.49±52.23, 23.32±52.30, 23.20±53.10, 23.15±52.83, and 22.99±52.41 mg, respectively. Volume scores were 68.7±140.7, 67.8±139.8, 67.0±139.6, 65.7±137.2, 64.8±135.9, and 64.0±135.0 mm^3, respectively (all $P\leq0.001$). There was no statistically significant difference in the average value in the ascending aorta and plaque maximum value ($P>0.05$) ASIR-V led to the risk reclassification to a lower category in 10 patients, including 8 from low to very low, and 2 from moderate to low based on Agatston scores.

Conclusion: ASIR-V results in image noise and calcium score reduction and may result in risk reclassification to a lower category.
Limitations: The results of this single-centre study were limited to only one scanner and one iterative reconstruction algorithm. The sample size of patients was small, which may affect the statistical results for the calcium score and risk reclassification.

The fight between CAD-RADS and the calcium score: who is the winner?
R. Malagò[1], G. Tabacco[1], S. Peretto[1], M. Poletti[2], M. Mochen[3], G. Salandini[1], M. Pernigotto[1], G. Mansueto[1]; [1]*Verona/IT,* [2]*Cles/IT,* [3]*Dimaro/IT*

Purpose: To compare the prognostic value of CAD-RADS classification with the calcium score relative risk.
Methods and materials: With a series population from a single-centre study of 1,918 pts (1,167 M, 751 F, mean age 63yrs) who underwent CA-MDCT from April 2008 to September 2019, we reconstructed and scored each exam, classifying the detected lesions and plaques according to the CAD-RADS system. 1,850/1,918 pts underwent additional pre-contrast coronary artery calcium protocol (Ca score). We determined the calcium burden of atherosclerotic plaques in these exams, according to Agatston method, and the relative risk of coronary events adjusted for patients age and gender. A correlation between the Agatston score and CAD-RADS was obtained using a Spearman test.
Results: Patients with significant stenosis (CAD-RADS 3) showed an extensive degree of coronary artery calcification (average value of Ca score: 1,052), with a discrete to moderate relative risk (76%). Patients with an occluded vessel (CAD-RADS 5) had a higher degree of coronary artery calcification (average value of Ca score: 1,929) and a moderate to high relative risk (87%).
Good correlation was recorded between calcium score and CAD-RADS, in case of Ca score 0 and CAD-RADS 0-1 and CAD-RADS 4 and 5 and Ca score severe (Rho 0.9 and 0.86 respectively P< 0.001), significant but a lower correlation in case of a moderate Ca score and CAD-RADS 3 (rho 0-67 p<0.001).
Conclusion: CAD-RADS better describes the overall plaque extension and degree of significance than a Ca score.
Limitations: Study population is not homogeneous for risk factors.

RPS 1403a-12 12:15
Fully automated calcium scoring algorithms for phantom experiments
G. D. van Praagh[1], N. R. van der Werf[2], M. Voet[3], J. Wang[1], D. Fleischmann[1], M. Greuter[3], T. Leiner[2], M. J. Willemink[1]; [1]*Stanford, CA/US,* [2]*Utrecht/NL,* [3]*Groningen/NL (gijsvanpraagh@live.nl)*

Purpose: Anthropomorphic phantoms containing calcifications are often used in coronary calcium scoring (CCS) studies. Manually quantifying CCS is highly time consuming. Accordingly, we aimed to develop and validate a fully automatic method for CCS in a commercially available phantom using two commonly used computer-programming languages.
Methods and materials: An anthropomorphic thorax phantom with cardiac calcification insert containing 9 cylindrical calcifications was used. An extension ring was used to simulate larger patients. Scans were acquired on an electron-beam tomography system and 5 state-of-the-art CT systems from 4 major vendors using routine protocols with 130 and 120 kVp, respectively, 3 mm slice thickness and filtered back-projection. To simulate interscan variability, each acquisition was repeated 5 times after repositioning the phantom. The robustness of CCS quantification-algorithms was assessed by evaluating a variety of settings on one CT-system. CCS was determined with vendor-specific software and quantified as an Agatston score. We developed 2 fully automated algorithms in 2 programming languages: MATLAB and Python. Besides CCS, image quality analysis functions were implemented into the algorithm (standard-deviations of a water-equivalent region-of-interest and noise power spectrum). To assess CCS accuracy of the algorithms, CCS was compared with their values obtained with the vendor-specific software using Bland-Altman and intraclass correlation analyses.
Results: Both algorithms achieved high agreements with vendor-specific software for Agatston scores (mean ± 95% confidence-interval for MATLAB and Python, respectively: -0.3% ± 4.0% and -0.1% ± 3.8%; ICCs were excellent for MATLAB and Python: 1.00 (1.00-1.00) for both). Output of the algorithms from one scan was given in <5 seconds.
Conclusion: We developed two algorithms to fully automatically quantify calcifications and evaluate image quality in a commercially available phantom with excellent agreement compared to vendor-specific software.

The role of computed tomography staging imaging in the prediction of the pathological depth of invasion (DOI) in oral cancer
M. Pietragalla[1], L. G. Locatello[2], C. Nardi[2], F. Mungai[1], L. Bonasera[2], C. Taverna[2], L. Novelli[2], S. Colagrande[2], V. Miele[2]; [1]*Pistoia/IT,* [2]*Florence/IT (michelepietragalla@hotmail.it)*

Purpose: Depth of invasion (DOI) has been introduced into the latest TNM classification of oral squamous cell carcinoma(OSCC) as a required parameter to correctly define T staging and prognosis. Despite its primarily pathologic definition (pDOI), there is increasing evidence that radiological DOI (rDOI) can preoperatively predict its final value even though a standard and practical definition is lacking. We wanted to assess the clinical impact and utility of computed tomography-derived (CT) rDOI in a cohort of OSCC patients and to better define its measurement.
Methods and materials: We retrieved 58 cases of OSCC operated on at our institution from 2016-2019. After accounting for plane-specific shrinkage factors and different oral subsites, we compared pDOI and rDOI for each spatial plane by a paired difference test and correlation coefficient. Radiological accuracy and survival analysis were also determined to identify the rDOI's clinical value.
Results: For the lateral tongue, pDOI was more strongly related with axial rDOI (ρ=0.923, P<0.01). For the hard palate, the best plane was the sagittal one (P<0.01). In floor-of-mouth (FOM) lesions and cheek buccal mucosa, the strongest correlation was with coronal rDOI (P<0.01). Sagittal scans seem to be the best to evaluate the dorsum of the tongue and retromolar trigone. Gengiva (P<0.01) was more correctly evaluated in the coronal plane. The overall accuracy of rDOI restaging was 75.41%. Disease-free survival seems to be worse as rDOI increases, although differences are not statistically significant (log-rank, P=0.204).
Conclusion: CT-derived rDOI can be of great value in the preoperative assessment of OSCC. We have identified specific spatial planes where its measurement is more strongly related to final pathological report and we hope that a standardisation of imaging and pathological analysis is needed.

Correlation of MRI derived parameters and SUV uptake obtained from FDG- PET-CT with human papillomavirus status in oropharyngeal squamous cell carcinomas

A. Jajodia, V. Mahawar, A. S. Rao, A. K. Chaturvedi*; New Delhi/IN (drmahawarvivek@gmail.com)*

Purpose: A favourable response to (chemo) radiotherapy (CCRT) is seen in human papillomavirus (HPV)-positive OPSCC patients. The apparent diffusion coefficient (ADC) derived from MRI has been shown to predict treatment response. We evaluated the correlation between the clinico-demographic profile of oropharyngeal squamous cell carcinomas patients (OPSCC patients), HPV status, and ADC values with SUV uptake obtained from FDG- PET-CT.
Methods and materials: The study population was obtained from a historical cohort diagnosed with HPV-related OPSCC. A total of 105 OPSCC patients who had undergone molecular testing for HPV status by p16 with immuno-histochemistry (IHC) were identified. 96 patients had pretreatment imaging (either PET-CT or MRI) and post CCRT imaging was included. Imaging was evaluated by head and neck radiologists to calculate the mean ADC and SUV max. Pearson's Chi-square and ANOVA analyses were performed to evaluate the correlation.
Results: 26 OPSCC were HPV-positive. HPV-positive HNSCC showed significant association with smoking (p=0.016), grade (p=0.013), the stage of the tumour (p<0.0001), T status (p=0.011), response to CCRT (p00.026), lymph nodes (p=0.042), and ADC values on follow-up imaging (p=0.007). The change in ADC was significantly correlated with P16 status (p=0.010) and percentage change in p16 status was marginally correlated (P=0.058).
Conclusion: In OPSCC patient's positive HPV status correlates with the follow-up mean apparent diffusion coefficient. The complementary prognostic value of the post-treatment apparent diffusion coefficient might be partially ascribed to patients with a positive HPV status. Further studies are reasonable to determine whether PET-CT is a useful imaging biomarker in comparison to ADC to risk-stratify patients with HPV-related OPSCC.
Limitations: A small cohort.

Redirection of parasagittal cuts of magnetic resonance imaging for the temporomandibular joint

M. K. Zayet*; Cairo/EG (mohamed.zayet@dentistry.cu.edu.eg)*

Purpose: Magnetic resonance imaging (MRI) is the main imaging modality in the diagnosis of temporomandibular disorders. Furthermore, sagittal cuts are the chief plane in diagnosing these disorders. This study aimed to investigate the capability of parasagittal cuts taken parallel to the lateral pterygoid muscle in depicting the structures of the temporomandibular joint.
Methods and materials: 20 symptomatic temporomandibular joint (TMJ) patients performed MRI bilaterally using traditionally used parasagittal cuts and another plane parallel to the lateral pterygoid muscle. Four-point scale was used to assess the clarity of articular disc position, disc morphology, cortical bone, and overall quality of the images of both investigated techniques in closed and open positions. Moreover, the final diagnosis of the cases was obtained in each technique.
Results: The mean and standard deviation of muscular aligned cuts in the clarity of revealing disc position, disc position, cortical bone, and overall image quality in closed position were 2.83± 0.39, 2.63± 0.49, 2.53± 0.51, and 2.83± 0.39, respectively, while those for traditional plane were 2.55± 0.50, 2.43± 0.50, 2.80± 0.41, and 2.53± 0.51, with the same order. In the open position, the same investigated points got 2.80± 0.41, 2.73± 0.45, 2.73± 0.45, and 2.80± 0.41 in muscular aligned images, and 2.78± 0.42, 2.65± 0.48, 2.82± 0.39, and 2.78± 0.42 in the traditional plane. Both techniques provided the same diagnosis in 97.5% of cases.
Conclusion: Parasagittal magnetic resonance images taken parallel to the lateral pterygoid muscle have higher image quality than a traditional plane in revealing temporomandibular structures.
Limitations: Small number of cases (40 temporomandibular joints).
Ethics committee approval: The study was approved by the research ethics committee of Faculty of Dentistry, Cairo University (19-4-18).

Visualisation of mandible fractures with the affection of the inferior alveolar nerve with high-resolution MRI sequences

E. Burian, L. Ritschl, M. Probst*; Munich/DE (e.burian@gmx.net)*

Purpose: Computed tomography (CT) or cone-beam computed tomography (CBCT) are the gold standards in clinical traumatology imaging when structures of the head and neck region are involved. However, CT and CBCT harbour inherent limitations in regards to soft tissue visualization. In mandible fractures, the inferior alveolar nerve (IAN) is at particular risk for damage. The aim of this study was to assess the IAN pre- and postoperatively and correlate elevated signal-to-noise-ratios (SNR) with potential sensitivity impairment.
Methods and materials: 18 patients suffering from a mandible fracture were examined on a 3T scanner. The conducted sequence protocol consisted of a 3D STIR, 3D WATS, and a 3D T1 FFE "black bone"-sequence (15 min scan time). Nerve function was assessed as normal, hypesthesia, anesthesia, or allodynia.
Results: The 3D T1 TFE sequences allowed for fracture detection in all patients. The 3D STIR sequence showed the highest SNR with regard to potential nerve damage (p<0.05). Besides some diagnostic accuracy in fracture detection like with CT, the direct visualisation of nerve structures was possible. Positive clinical nerve testing correlated with physiological SNR and hypoesthesia correlated with increased SNR (p<0.05).
Conclusion: The study highlights the feasibility of MRI for fracture detection and affection of the IAN. The applied sequence protocol showed comparable diagnostic power in detecting mandible fractures as with CT. Additionally, a reliable assessment of potential IAN damage with a good correlation to clinical sensory testing could be achieved.
Applying the described sequence protocol allowed for precise fracture detection as well as reliable nerve damage assessment.
Limitations: Motion artefacts due to a scan time of approximately 10 min.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

In vitro validation of a digital subtraction radiography (DSR) system in detecting root canal (RC) density changes

G. Trifylli[1], I. C. Mackie[2]*; [1]Nikaia/GR, [2]Manchester/UK (gtrifili@yahoo.com)*

Purpose: To calculate the accuracy and reliability of a DSR system when in vitro changes were made on anterior maxillary incisor teeth, which simulate post-traumatic complications (e.g. continued root development and pulp canal obliteration).
Methods and materials: Subtle RC density changes were made through filing 15 teeth which were then placed in customised acrylic sockets in a skull. Baseline and subsequent digital radiographs were taken after the use of 40, 60, and 90 K file size, and after no filing. During the image acquisition stage, standardised conditions, in terms of image geometry and density, were achieved by using a cephalostat method of head stabilisation (cephalostat headset and a customized film holder) and software for image processing. DSR was applied and the subtraction images represented small, medium, large, or no RC density change (gain or loss). Radiographic assessment slides were done by 3 observers. Observer A assessed the slides at two different times.
Results: DSR sensitivity (0.93-0.96 at a possible cut-off point, 0.78-0.82 at a probable cut-off point, and 0.44-0.62 at a definite cut-off point), specificity (perfect: 1.00), Youden's J index (range between 0.44 and 0.96 at all the cut-off points), intraexaminer agreement (wk: 0.96, 95% CI: 0.93-0.99) and interexaminer agreement (wk range: 0.90-0.95, 95% CI: 0.83-0.98) were calculated. The results were analysed in relation to the site, size, and kind (gain or loss) of the density change.
Conclusion: DSR led to a more accurate and reproducible diagnosis. Highly accurate dignoses of small lesions at a low degree of confidence (sensitivity: 0.80-0.87) proved DSR to be a diagnostically useful tool, particularly when early detection of tooth density change is needed.

Densitometric analysis of the condyle and axis in determining osteoporotic risk: a CBCT study

A. Uri, B. Evlice*; Adana/TR (alevuri@gmail.com)*

Purpose: To evaluate the usefulness of radiological density measurements of mandibular condyle (MC) and axis vertebra (AV) in patients with a risk of osteoporosis according to mental index (MI) values.
Methods and materials: Cone-beam computed tomography (CBCT) images of 96 patients were retrospectively analysed. Radiological density values of AV and MC (left and right), and measurements of MI (left and right), were performed from the areas formed by reference lines in the coronal section. Demographic data of patients such as age and gender were recorded. Patients were divided into two groups according to the mean age and into two categories as high and low risk according to the risk of osteoporosis by taking MI values (cut-off value: 3.0 mm) into the consideration. ROC curve analysis was used to determine the power of MC and AV's radiological densities to explain the risk of osteoporosis.
Results: There was a statistically significant difference between gender and MI values, and age groups and MC, AV, and MI values. In addition, MC and AV mean values were significantly lower in patients with a high risk of osteoporosis than in low-risk patients. There was a positive correlation between MC, AV, and MI variables in different strengths. Finally, the results of the ROC curve analysis showed that MC was more powerful with a lower difference than AV in determining the risk of osteoporosis.
Conclusion: MC and AV measurements are considered to be important predictors in determining the osteoporotic risk.
Limitations: The cut-off value of MI was considered as 3.0 mm, however, this value might be related to race or ethnicity.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

Radiomorphometeric evaluation of the clivus in an Indian paediatric population visiting a tertiary dental hospital: a cone-beam computed tomography study

A. Chaurasia*; Lucknow/IN (chaurasiaakhilanand49@gmail.com)*

Purpose: To determine the age and sex-related changes in clivus length and clivus width. Clivus width and clivus length were also evaluated for the age prediction of individuals.
Methods and materials: The CBCT images of 150 study subjects obtained from Carestream 9000cc (USA) CBCT machine at 90 Kvp, 4 mA for 11.3 seconds at FOV (17"×13.5"), voxel size of 300 in the age group of 6 to 17 years (76 male, 74 female) were chosen prospectively. The clivus length and clivus width were measured using trophy Dicom ink software on axial and sagittal images (DICOM images). An unpaired t-test and ANOVA test were used for comparison between groups. Pearson correlation coefficients were used to evaluate the correlations. The data analysis was done using SPSS version 21.0.
Results: Irrespective of age and sex, the mean clivus width was 28.8±3.98 and mean clivus length was 42.7±3.98. Statistically, no significant difference was observed between males and females ($p>0.05$) with clivus width. However, the clivus length was statistically significant ($p<0.001$) in both male and female populations. The clivus width and clivus length was directly associated with age. The mathematical equations derived from linear regression analysis can be used in the prediction of the age of an individual if the clivus width/clivus length is known.
Conclusion: The clivus measurements on CBCT can be used to predict the age of an individual in medicolegal disputes. As the Pearson correlation coefficient showed through strong associations between the clivus measurements, age, and gender, clivus measurements can be used to differentiate between the sex of humans and helps in age determination. Clivus dimensions can be used as an additional parameter in age and sex determination in inconclusive medicolegal cases.
Limitations: n/a
Ethics committee approval: Ethics committee approval obtained.

Comparison of the diagnostic value of CT signs of lacrimal sac dilatation in patients with dacryocystitis with verbal reporting and virtual endoscopy

A. Ageev[1], A. Dergilev[2], V. A. Obodov[1], A. Obodov[1]; *[1]Yekaterinburg/RU, [2]Novosibirsk/RU (ageev.artem@gmail.com)*

Purpose: To specify normal and pathologic values and intervals of main numeric CT signs of lacrimal sac dilatation to compare the diagnostic value of those CT signs and to compare the diagnostic value of virtual endoscopy (VE) and conventional text reports for LS position description for intraoperative navigation purpose.
Methods and materials: 102 adult patients with dacryocystitis were included in this study. 204 CT volumes including lacrimal sacs (LS) and nasolacrimal ducts (NLD) images were obtained.
The main group included CT images of 123 LS and NLD on the affected side.
The control group included CT images of 81 LS and NLD of the same patients on the intact side, excluding patients with bilateral dacryocystitis.
Pearson's Chi-square test and receiver operating characteristic curve (ROC) analysis were applied to the collected data.
Results: CT signs of normal LS volume were specified: volume ≤0,29±0.1 cm^3 (sensitivity 73.17%, specificity 90.12%), height ≤13.9±1.3 mm (sensitivity 68.29%, specificity 74.07%), width ≤5.9±0.2 mm (sensitivity 65.85%, specificity 91.36%), and depth ≤6.55±0.4 mm (sensitivity 89.43%, specificity 74.07%).
The diagnostic value of CT signs of LS dilatation was found regressing in the following sequence: volume (area under the curve, AUC=0.886), depth (AUC=0.865), width (AUC=0.841), height (AUC=0.734), upper dislocation (AUC=0.586), and forward dislocation (AUC=0.564).
Significant differences in the diagnostic accuracy of text reports and VE were found: χ^2=52.61 ($P<0.0001$) and AUC difference 0.418±0.03 (VE AUC=0.992±0.01, text reports AUC=0,574±0,1).
Conclusion: LS volume is the most accurate CT sign of LS dilatation in patients with dacryocystitis. VE is better for LS position description than text reports and thus VE is recommended for routine clinical use.
Limitations: The numeric criteria of LS dilatation in children and other races will probably be different.

Evaluation through dacryo-CT of the relapse of epiphora after dacryocystorhinostomy

G. Salandini, M. Maturi, E. Genco, F. de Cecco, S. Mehrabi, G. Mansueto*; Verona/IT (giulia.salandini06@gmail.com)*

Purpose: To evaluate computed tomography dacryocystography (dacryo-CT) as an imaging method to identify the relapse of stenosis in patients with a recurrence of epiphora after dacryocystorhinostomy, as well as providing useful information to plan a new surgical operation.
Methods and materials: A retrospective study was performed including patients who underwent a dacryo-CT from January 2014-September 2019 in the AOUI of Verona. Patients who underwent dacryocystorhinostomy and presented with a recurrence of epiphora were identified.
The following qualitative variables were considered: relapse of stenosis, failure of the surgical shunt, patency of the nasolacrimal duct downstream, and the presence of anatomical variants.
Results: Patients who underwent dacryo-CT after dacryocystorhinostomy were 10 in total, 8 who underwent a monolateral dacryocystorhinostomy and 2 who underwent a bilateral dacryocystorhinostomy.
5 males and 5 females patients, aged between 32 and 88, were examined.
7 of the 10 patients had a relapse of stenosis of the lacrimal drainage apparatus.
Among the patients with a failure of the surgical shunt, 4 had a nasal septal deviation, 2 had sinusitis, and 1 presented with a total opacification of the maxillary sinus due to possible relapse of his previous underlying disease (inverted papilloma).
Among the 3 patients who had regular patency of the surgical shunt after the dacryocystorhinostomy, 1 developed contralateral stenosis of the nasolacrimal duct and 1 developed a mucocele of the lacrimal sac in the same side of the dacryocystorhinostomy, which was regularly patent.

Conclusion: Dacryo-CT is an optimal imaging method to identify the causes of failure of surgery and to plan a possible second operation.
Limitations: The low sample size and the retrospective nature of the study.
Ethics committee approval: n/a

Assessment of the internal nasal valve angle by computed tomography: a new method proposal and a revision of current techniques
N. Janovic, A. Janovic, B. Pavlovic, M. Dimitrijevic, M. Djuric*; Belgrade/RS (aleksa.janovic@stomf.bg.ac.rs)*

Purpose: To test a new CT method for the internal nasal valve (INV) angle measurement and compare it with current techniques and endoscopy.
Methods and materials: 40 INV angles in 20 adult patients (mean age 38.25±10.9) were measured on CT images using a "nasal base view (NBV)" method and a new method and compared by Student's t-test. All patients were candidates for functional endoscopic sinus surgery (FESS) and preoperative CT examination. The exclusion criteria were a history of external nose trauma, septoplasty, esthetic nasal reconstructions, and diseases that may distort the INV angle. Angles were also measured on endoscopic images and correlated statistically with CT techniques. Measurements were made by two radiologists independently, and the interclass correlation coefficient (ICC) was calculated.
Results: INV angles were not significantly different between NBV and the new method (t=-1.256, p=0.216), although the new method provided slightly higher angles (NBV 11.19 ± 3.62 vs. the new method 11.86 ± 3.90). Both methods correlated significantly with angles measured on endoscopy images, but a much stronger correlation was detected with the new CT method (R=0.387, p=0.014 vs. R=0.808, p<0.001). The new CT method showed a stronger level of agreement (ICC=0.930) between radiologists in contrast to the NBV method (ICC=0.658).
Conclusion: A stronger correlation with nasal endoscopy and a better reproducibility gives priority to the new CT method for the INV angle measurement in daily radiological practice.
Limitations: A relatively small number of patients might limit the study. The INV narrowing was not diagnosed in all patients who participated in the study.
Ethics committee approval: The study was approved by the Ethics Committee of the Faculty of Medicine, No. 29/V-1.
Funding: No funding was received for this work.

MRI detects chronic rhinosinusitis in infants and preschool children with cystic fibrosis
M. O. Wielpütz, O. Sommerburg, F. Wuennemann, E. Optazaite, M. Stahl, H.-U. Kauczor, I. Baumann, M. A. Mall, M. Eichinger*; Heidelberg/DE (wielpuetz@uni-heidelberg.de)*

Purpose: Chronic rhinosinusitis (CRS) contributes to the disease burden of patients with cystic fibrosis (CF). However, its onset and progression in infants and preschool children with CF remain poorly understood. Our aim was to determine the prevalence and extent of CRS in early CF using magnetic resonance imaging (MRI).
Methods and materials: MRI was performed in 67 infants and pre-school children with CF (mean age 2.3±2.1y, range 0-6y), and 30 non-CF controls (3.5±2.0y). Paranasal sinus dimensions and structural abnormalities including mucosal swelling, mucopyoceles, and nasal polyps of the maxillary, frontal, sphenoid, and ethmoid sinuses, and in addition medial maxillary sinus wall deformation, were assessed using a novel CRS MRI scoring system.
Results: Pneumatisation and dimensions of paranasal sinuses did not differ between the two groups. MRI detected an increased prevalence of mucosal swelling (83% vs 17%, P<0.001), mucopyoceles (75% vs 2%, P<0.001), polyps (26% vs 7%, P<0.001), and maxillary sinus wall deformation (68% vs 2%, P<0.001) in CF compared to controls. Furthermore, the extent of these abnormalities was also increased with an MRI sum score of 22.9±10.9 in CF compared to 4.5±7.6 in non-CF controls (P<0.001).
Conclusion: MRI detected normal dimensions of paranasal sinuses and a high prevalence and severity of paranasal sinus abnormalities due to CRS in infants and preschool children with CF without radiation exposure. Our results support the development of MRI for sensitive non-invasive diagnosis and the monitoring of CRS in young children with CF, and as an outcome measure for clinical trials.
Limitations: We did not assess the relationship between structural abnormalities and disease burden obtained by a questionnaire.
Ethics committee approval: Approved by the institutional ethics committee and informed written consent was obtained from parents or legal guardians.

Imaging of the pulmonary vasculature in congenital heart disease without gadolinium contrast: intraindividual comparison of a novel compressed SENSE accelerated 3D REACT with 4D CE-MRA
L. Pennig[1], A. Wagner[1], K. Weiss[1], S. Lennartz[1], D. Maintz[2], T. Hickethier[1], C. P. Naehle[3], A. Bunck[1], J. Doerner[3]*; [1]Cologne/DE, [2]Münster/DE, [3]Bonn/DE (lenhard.pennig@uk-koeln.de)*

Purpose: To compare a novel compressed SENSE accelerated (factor 9) ECG- and respiratory-triggered 3D relaxation-enhanced angiography without contrast and triggering (REACT-non-CE-MRA) with standard non-ECG-triggered time-resolved 4D contrast-enhanced MRA (4D CE-MRA) for imaging of the pulmonary vasculature in patients with congenital heart disease (CHD) at 1.5T.
Methods and materials: This retrospective analysis of 25 patients (06/2018-04/2019) with known or suspected CHD was independently conducted by two radiologists executing measurements on REACT-non-CE-MRA and 4D CE-MRA on 7 dedicated points (inner-edge): main pulmonary artery (MPA), right and left pulmonary artery, right superior and inferior pulmonary vein, left superior (LSPV), and inferior pulmonary vein. The image quality for arteries and veins was evaluated on a four-point scale in consensus.
Results: 23 of 25 patients presented with CHD. There was a high interobserver agreement for both methods of imaging at the pulmonary arteries (ICC ≥ 0.96); at pulmonary veins, REACT-non-CE-MRA showed a slightly higher agreement, pronounced at LSPV (ICC 0.946 vs 0.895). Measurements in 4D CE-MRA reached higher diameter values compared to REACT-non-CE-MRA at the pulmonary arteries with significant difference (e. g. MPA: mean 0.408 cm, p=0.002). REACT-non-CE-MRA (average acquisition time 07:01 ± 02:44 min)

showed significantly better image quality than 4D CE-MRA at the pulmonary arteries (3.84 vs 3.32, p=0.0002) and veins (3.32 vs 2.72, p=0.0152).
Conclusion: Compressed SENSE accelerated 3D REACT-non-CE-MRA allows for reliable and fast imaging of the pulmonary vasculature with higher image quality and slightly higher interobserver agreement than 4D CE-MRA without contrast agent and associated disadvantages. Therefore, it represents a clinically suitable technique for patients requiring repetitive imaging of the pulmonary vessels, e.g. patients with CHD.
Limitations: A retrospective study. No comparison to DSA.
Ethics committee approval: Ethics committee approval was given and consent was waived.
Funding: No funding was received for this work.

Long-term follow-up of extracardiac Fontan procedure by CCT and CMR
M. Caicoya[1], M. Bret Zurita[1], I. Miguelsanz Martínez[2], E. Cuesta López[1], F. Gutiérrez-Larraya Aguado[1], E. Sanchez Pascual[1]; [1]Madrid/ES, [2]Tres Cantos/ES (martin.boto@gmail.com)

Purpose: In over 20 years of experience in congenital cardiopathy imaging in our tertiary hospital, we have witnessed the evolution of univentricular heart (UVH) surgery up to the arrival of Fontan procedure. We want to describe the late complications of patients with extracardiac Fontan correction and to familiarise radiologists with technical considerations for optimal image acquisition to avoid diagnostic pitfalls.
Methods and materials: Cardiac computed tomography (CCT) was performed in a 320-MDCT (Aquillion one, Canon Medical Systems S.A.®), with acquisition of an EKG-gated arterial phase and a 70 s-delayed phase (whole thorax). Cardiac-MRI (CMR) was obtained in a 3T system (Magnetom Skyra, SIEMENS®). EKG-gated dark and bright-blood, cine turbo-FLASH, PC in ascending aorta and AV valve, 3D Angio-MRI (wide FOV including upper abdomen) in arterial and venous phases, and late gadolinium enhanced sequences were obtained. Gadolinium contrast (3 mmol/Kg b.w.) was administered.
Results: We recruited 20 patients (18-26 years old). The mean follow-up period was 14 years. 9 (45%) patients had right and 11 (55%) patients had left morphological UVH. The average EF was 53.8%. 2 cases had ventricular EF<45%. Fontan stenosis was found in 4 patients (20%). 9 cases (45%) showed AV regurgitation and 2 patients (10%) presented with aortic regurgitation. Vascular complications (n=13) included 9 (45%) veno-venous and 2 (10%) arteriovenous fistulae. 10 cases (50%) had hepatic lesions.
Conclusion: CMR and MDCT are essential for follow-up and detection of late complications of extracardiac Fontan correction. The appearance of these complications may indicate the start of the Fontan failure.
Special imaging acquisition protocols are required for optimal evaluation of Fontan connections and complications.

Is IVIM enough to assess hepatic injury in post-repair tetralogy of Fallot?
S. Baş Özkök, M. Sorkun; *İstanbul/TR (minealacagoz@gmail.com)*

Purpose: Although congestive hepatopathy is well explained in Fontan circulation and intravoxel incoherent motion (IVIM) was performed for liver injury, no reports have been published about liver injury in post-repair TOF patients by IVIM parameters. We aimed to research in post-repair TOF patients whether cardiac MRI (CMR) and laboratory findings correlate with liver injury by IVIM parameters.

Methods and materials: 30 patients with post-repair TOF (15.46±7.64 years old, F/M: 15/15) and 25 healthy controls (18.53±5.73 years old, F/M: 15/10) were included. IVIM sequences were revealed after CMR examination by a 1.5T scanner and 32-channel phased-array surface coil.
IVIM values (D, D*, and perfusion fraction) were measured by locating ROI in 8 segments of the liver. Pulmonary artery regurgitation fraction (RF), right and left end-diastolic volume index (LVEDVI, RVEDVI), and ejection fraction (LV-EF, RV-EF) were correlated with IVIM parameters in post-repair TOF patients.
Results: Mean LVEDVI, LV-EF, RVEDVI, RV-EF, and pulmonary artery RF were 92.3±21.43ml/m^2, 48.63±5.96%, 172.57±41.32ml/m^2, 39.53±6.37%, and 46.03±10.83, respectively. There was a significant difference between DWI, DTrue, and perfusion fraction of post-repair TOF (DWI: 177.50±126.78 mm^2/second versus 205.70±82.15 mm^2/second (p = 0.00318), DTrue 0.00165±0.0005 mm^2/second versus 0.00144±0.0008 mm^2/second, D* 0.068±0.075 versus 0.079±0.074 mm2/second (p = 0.12602), perfusion fraction 34.68±16.95% versus 29.57±12.56% (p =0.00001), and D*fraction 0.365±0.089 % versus 0.380±0.077%, respectively). There was no statistically significant correlation between IVIM parameters and CMRI measurements.
Conclusion: Liver injury can be seen independently from cardiac parameters. Evaluation of the liver should be added to annual cardiac check-ups. DWI, DTrue, and perfusion fraction parameters can be used for evaluating liver injury in post-repair TOF patients and assessing capillary perfusion and connective tissue/cell density by IVIM sequences.
Limitations: A relatively small sample size. A lack of histopathologic correlation with imaging.
Ethics committee approval: Institutional Review Board approval. Written informed consent was obtained.
Funding: No funding was received for this work.

Multiparametric myocardial mapping of paediatric cardiac tumours: preliminary results in comparison with conventional cardiac MR evaluation
V. Bordonaro, D. Curione, T. P. Santangelo, P. Ciancarella, C. Napolitano, P. Ciliberti, A. Secinaro; *Rome/IT (bordonaroveronica@gmail.com)*

Purpose: To evaluate the diagnostic role of native T1, ECV, and T2 values of paediatric cardiac tumours.
Methods and materials: We retrospectively included 8 paediatric patients (mean age 8.25 ± 3.62 years, range 2-16; 6 femmine) with suspected cardiac masses (2 fibromas, 2 angiomas, 1 rhabdomyoma, 1 teratoma, 1 myxoma, and 1 lipoma) who underwent cardiac MRI on a 1.5T scanner using T2 and pre- and post-contrast T1 mapping sequences. Native T1, ECV, and T2 values were obtained as an average among 3 non-overlapping ROIs placed into the lesion and an additional ROI covering the whole mass. The analysis was performed by two experienced readers, blinded to the suspected diagnosis.
Results: The 2 fibromas showed native T1 values of 972 ± 96 ms, ECV values of 100% ± 2, and T2 of 47 ± 2 ms. The 2 angiomas had native T1 of 1,310 ± 48 ms and ECV of 57% ± 5 and T2 of 78 ± 2 ms. The rhabdomyoma had native T1 of 1,420 ms, ECV of 29%, and T2 of 73 ms. The teratoma showed native T1 values of 1,378 ms, ECV of 29%, and T2 of 58 ms. The myxoma had native T1 values of 1,644 ms, ECV of 74%, and T2 of 126 ms. The lipoma showed native T1 values of 215 ms, undetectable ECV, and T2 of 89 ms.
Conclusion: Preliminary data obtained from this small series of paediatric tumours suggests that ECV values trend towards a higher reproducibility and better correlates with the suspected diagnosis derived from a conventional MRI approach compared to native T1 and T2 values (e.g. ECV=100% in fibromas, normal ECV in rhabdomyoma, and ECV equal to plasmatic component in angiomas).

Possibilities of CT-angiocardiography in single ventricle defect diagnostics

T. Tazhigaliyeva; *Nur-Sultan/KZ (torgyn.tazhigaliyeva@gmail.com)*

Purpose: To explore the possibilities of CT-angiocardiography in the single ventricle of the heart (SVH) diagnostics.
Methods and materials: Studies were conducted in the radiology department of JSC "National Research Cardiac Surgery Center" from October 2011 to December 2018, inclusive. 1,844 patients with suspected CHD were examined, 125 (6,8%) of whom had a SVH: females - 59 (47,2%), males - 66 (52,8%).
Results: The studies results of 125 SVH patients were analysed; 70 (56%) via right ventricular hypoplasia (type A), 32 (25.6%) via left ventricular hypoplasia (type B), and 23 (18.4%) via a single ventricle (type C).
A single ventricle was diagnosed at the age of 1 up to 6 months in 74 (59.2%) patients, from 6 months to 1 year in 14 (11.2%) patients, from 1 to 5 years in 18 (14.4%) patient, from 5 to 10 years in 4 (3.2%) patients, and over 10 years in 15 (12%) patients.
SVH with other CHDs combination: atrial septal defect in 86 (68.8%) patients, patent ductus arteriosus in 70 (56%) patients, transposition of the great arteries in 51 (40.8%) patients, ventricular septal defect in 57 (45.6%) patients, pulmonary atresia in 28 (22.4%) patients, anomalous pulmonary veins drainage in 26 (20.8%) patients, patent foramen ovale in 19 (15.2%) patients, double superior vena cava in 15 (12%) patients, and coarctation of the aorta in 9 (7.2%) patients.
89 (71.2%) patients were operated on and 36 (28.8%) were not operated on, of which 56 had positive outcomes (62.9%) and 34 resulted in death (38.2%).
Conclusion: CT-angiocardiography is a highly informative and minimally invasive method for SVH diagnostics, replacing invasive methods such as cardiac catheterisation and angiocardiography. Sensitivity was 96.7%, specificity was 97.4%, and accuracy was 96.7%.

Correlation between changes in cardiac iron and hepatic iron in paediatric patients with thalassemia major

A. Pepe[1], A. Meloni[1], A. Filosa[2], L. Pistoia[1], E. Grassedonio[3], R. Righi[4], P. Preziosi[5], V. Positano[1], M. Casale[2]; [1]*Pisa/IT,* [2]*Naples/IT,* [3]*Palermo/IT,* [4]*Ferrara/IT,* [5]*Rome/IT (alessia.pepe@ftgm.it)*

Purpose: We evaluated if changes in myocardial iron overload (MIO) were related to baseline hepatic iron or changes in hepatic iron overload in children with thalassemia major (TM).
Methods and materials: We considered 68 TM patients enrolled in the MIOT project with <18 years at the first MRI and who performed a follow-up study at 18±3 months.
Myocardial and hepatic iron burdens were quantified by the T2* technique. Liver T2* values were converted into liver iron concentration (LIC) values.
Results: Baseline global heart T2* values were 29.72±11.21 ms and 16 patients showed baseline MIO (T2*<20 ms).
Mean percentage changes in global heart T2* values per month were 0.66±1.70 and they were significantly higher in patients with baseline MIO (1.99±2.53% vs 0.25±1.09% ms; P=0.002).
Percentage changes in global heart T2* values/month were not associated to initial MRI LIC values (R=0.048; P=0.695) or to final MRI LIC values (R=-0.134; P=0.277).
No correlation was detected between % changes in heart T2* and MRI LIC values (R=-0.244; P=0.067).
Conclusion: In paediatric TM patients, changes in MIO are not correlated to baseline MRI LIC values and changes in hepatic iron. Our data seems to not support the hypothesis that it is necessary to clean the liver before removing MIO.
Limitations: The limited sample size, however, TM is a rare disease.
Ethics committee approval: The study complied with the Declaration of Helsinki. The institutional review board approved this study. For all patients, parents gave their informed consent to the protocol.
Funding: The MIOT project receives "no-profit support" from industrial sponsorships (Chiesi Farmaceutici S.p.A. and ApoPharma Inc.).

Biventricular cardiac strain in patients with a tetralogy of Fallot: a cardiac magnetic resonance study

C. B. Monti[1], G. Guarnieri[1], U. Barbaro[2], D. Capra[1], M. Alì[1], F. Sardanelli[1], F. Secchi[1]; [1]*Milan/IT,* [2]*Messina/IT (caterinab.monti@gmail.com)*

Purpose: To evaluate left (LV) and right ventricular (RV) strain and their modifications over time in patients with a tetralogy of Fallot (ToF).
Methods and materials: We retrospectively evaluated patients with ToF with two cardiac magnetic resonances (CMR) performed between 2014 and 2019. We segmented epicardium and endocardium in both ventricles in long-axis end-systolic and end-diastolic cine images, and calculated LV and RV volumes, ejection fraction (EF), global longitudinal (GLS), and radial and circumferential strain for the LV and RV. We conducted analyses overall and divided patients into two groups according to whether they underwent pulmonary valve replacement between the two CMRs (Group-1) or not (Group-0).
Results: Our study population included 46 patients, of which 30 belonged to Group-0 and 16 to Group-1. EF remained unvaried from the first to the second CMR overall (from 55%,60-63% to 55%,50-60%, p=0.563,) and in subgroups (Group-0 from 57%,48%-65% to 55%,49-62%, p=0.534, Group-1 from 54%, 51-58% to 53%, 50-60%, p=0.763). Overall, RV GLS increased (p=0.017) from the first (-22.8%,-26.3--21.1) to the second CMR (-20.1%,-23.1--16.9%). In Group-0, RV-GLS increased (p=0.034) from the first (-23%,-26.9—21.9%) to the second CMR (-20.5%,-25.3– -16.7%), while in Group-1, RV-GLS remained unvaried (p=0.238) from the first (-22.6%,-24.8—19.6%) to the second CMR (-19.6%,-22.6—17%).
Conclusion: RV-GLS may represent an early biomarker of RV functional deterioration in patients with ToF. Furthermore, pulmonary valve replacement may stall the worsening of RV GLS.
Limitations: A retrospective, monocentric study. A small study sample.
Ethics committee approval: Ethics committee approval was obtained, informed consent was waived due to the retrospective nature of the study.
Funding: No funding was received for this work.

Right versus left ventricular blood pool ratio in T2 mapping: a simple method for detecting left-to-right shunts by CMR

T. Emrich[1], T. Schöler[1], I. A. Abidoye[2], T. Deisler[1], A. L. Emrich[1], P. Wenzel[1], C. Düber[1], A. Varga-Szemes[3], K.-F. Kreitner[1]; [1]*Mainz/DE,* [2]*Ado-Ekiti/NG,* [3]*Charleston, SC/US (tilman.emrich@gmail.com)*

Purpose: Left-to-right shunts (L-R-Shunt) lead to volume overload of the right ventricular system, pulmonary hypertension, and alterations of the RV myocardium, resulting in adverse cardiac events. CMR is able to detect L-R-Shunts by comparison of phase-contrast measurements of pulmonary and aortic flow (Qp/Qs-ratio), which is not routinely done in clinical CMR. T2-mapping is generally used for the analysation of myocardial oedema. Additionally, it is sensitive to the oxygenation of blood. This work evaluates an easy screening tool for the evaluation of L-R-Shunts using T2-mapping.
Methods and materials: We retrospectively analysed the ratio of T2-relaxation times of the LV/RV blood pool and Qp/Qs-ratio by phase-contrast-imaging from 5 patients with established relevant L-R-shunts. 7 healthy volunteers were used as a control group. Qp/Qs-ratio was calculated by dedicated measurements of pulmonary and aortic flow. In routinely acquired T2-maps of the mid-ventricular slice, the ratio between left and right ventricular blood pool T2-relaxation time was calculated.
Results: Compared to the control group, the L-R-Shunt-group showed relevant elevation of Qp/Qs and RV volume overload. T2 RV/LV-Ratio was significantly raised in patients with L-R-Shunts (0.93vs0.70, p=0.005). A ratio of >0.82 showed a 100% sensitivity and 85.7% specificity for detection of L-R-Shunts, resulting in a positive and negative predictive value of 83.3%, resp 100%. Alterations could also be depicted easily by visual assessment.

Conclusion: RV-LV blood pool T2-relaxation time ratio seems to be an easy and reliable method for the screening of L-R-Shunts. Elevated ratios of >0.82 should lead to a dedicated evaluation of Qp/Qs-ratio to determine the relevance of an L-R-Shunt. Despite its promising application, our preliminary results need to be validated in a larger study cohort.
Limitations: A single-centre study.
Ethics committee approval: The study was approved by the local ethics committee (2018-13520/837.196.13/837.477.14).
Funding: No funding was received for this work.

Anomalous ductus arteriosus connection and its relationship with the right aortic arch
M. Xie, H. Cao, L. Hong*; Wuhan/CN (Xiemx@hust.edu.cn)*

Purpose: To analyse the sonographic features of anomalous ductus arteriosus (DA) connection in the fetus and to investigate the relationship between anomalous ductal connection and the right aortic arch (RAA).
Methods and materials: Detailed fetal echocardiography was performed on 5,080 pregnancies referred to our hospital from 2014 to 2018. The three-vessel-trachea (3VT) view and DA transverse and long-axis view were chosen to observe the connection, course, dimension, and flow direction of DA. The presence of left/right/double-sided DA or aortic arch, vascular ring, and associated cardiovascular anomalies were evaluated.
Results: 41 fetuses (25.4±3.5 weeks) had anomalous DA connection and RAA was detected in all 41 cases. 21 fetuses (29/41) demonstrated a right-sided DA which abnormally connected between the pulmonary trunk (PT) or right pulmonary artery (RPA) and descending aorta (DAo). The other 12 cases (12/41) revealed a left-sided DA abnormally connected between the left pulmonary artery (LPA) and left subclavian artery (LSA). No vascular ring around the trachea was detected in all 41 cases. 5 cases (5/41) were isolated anomalous DA connection with RAA, while the remaining 36 cases (36/41) all demonstrated associated cardiac anomalies, including a tetralogy of Fallot (14/41), pulmonary atresia (9/41), double outlet right ventricle (6/41), transposition of the great arteries (3/41), and other cardiac anomalies. Reversed flow across DA was observed in 13 cases.
Conclusion: In our study, anomalous DA connection was always associated with RAA without forming vascular ring. The right-sided DA with anomalous connection between PT/RPA and DAo was more frequently seen than the left-sided DA abnormally connecting between LPA and LSA. DA abnormal connection is always accompanied with other cardiovascular anomalies.
Limitations: The embryonic developmental mechanisms of anomalous DA connection and its relationship with RAA still need further investigation.

Application of prospective ECG-gated multiphase scanning for coronary CT in children with different heart rates
S. Tang*; Chongqing/CN (sltang66@163.com)*

Purpose: To explore the application of prospective ECG-gated multiphase scanning in coronary CT imaging in children with different heart rates.
Methods and materials: In the control group, 200 children aged 2-4 years who underwent coronary CT examination in our hospital from January 2017 to December 2017 were retrospectively selected. They were divided into 5 groups according to the heart rate frequency: ＜75 beats/min, 75-85 beats/min, 86-95 beats/min, 96-105 beats/min, or 106-120 beats/min, with 40 in each group. Each child was treated with retrospective ECG-gated scanning technology. 6 groups of phase images were reconstructed: 40%, 45%, 50%, 70%, 75%, and 80%. The optimal phase was selected for coronary artery reconstruction.
Results: For the 2 groups with the same heart rate, the radiation dose in the study group was 72% lower than that in the control group. There was no significant difference in coronary artery image quality between the 2 groups at the optimal phase.
Conclusion: Applying prospective ECG-gated multiphase scanning technology to children's coronary CT imaging can significantly reduce the scanning radiation dose of children without affecting the quality of coronary artery image.
Limitations: The study was limited to children aged 3-4 years. Children with a heart rate higher than 120 beats/min were not included in the study, which needs to be further improved in future studies.
Ethics committee approval: The study protocol was approved by the Human Ethics Committee of the Children's Hospital of Chongqing Medical University. Written informed consent was obtained from the parents or guardians of all patients before the examinations.
Funding: No funding was received for this work.

Radiographer's assessment of referrals for CT and MR imaging using a web-based data collection tool
C. Chilanga[1], K. B. Lysdahl[1], H. M. Olerud[1], R. Toomey[2], A. Cradock[2], L. A. Rainford[2]; *[1]Kongsberg/NO, [2]Dublin/IE (chiluten72@gmail.com)*

Purpose: To investigate radiographers' compliance with guidelines in assessing CT and MRI referrals and determine factors that influenced their performance.
Methods and materials: 5 referral scenarios for each of CT and MRI were distributed to radiographers who volunteered at the EFRS Research Hub at ECR 2019. A web-based data collection tool designed by Ziltron Ltd was used. The radiographers were required to determine the appropriateness of each referral, highlight any concerns, and recommend suitable alternative investigations if applicable. An overall performance score from 0-5 was calculated and a linear regression analysis was used to determine factors that influenced the radiographers' performance.
Results: 91 (n= 5l CT, n=40 MRI) radiographers participated. 58% and 57% of responses were consistent with recommended guidelines for CT and MRI, respectively. Possession of an MSc qualification in CT was a significant predicting factor of consistency with the guidelines (p=0.02). Being a radiographer in a lead professional role and/or an educator was a significant predicting factor for a greater consistency with the guidelines (p=0.01) in MRI, and approached significance for CT (p=0.06). The routine use of referral guidelines was reported by 80% of participants.
Conclusion: Over 50% of the radiographers' responses complied with guidelines.
Limitations: There may be a selection bias as participants were ECR 2019 attendees and predominantly working in Europe. Caution in translating the outcomes beyond this cohort is warranted. Additionally, the referral cases were designed with minimal text to enable easy comprehension for non-native English participants, however, the impact of language must be considered.
Ethics committee approval: Ethical approvals were obtained from the UCD Institutional UREC in Ireland and NSD (reference number 776616) in Norway.
Funding: No funding was received for this work.

Image quality assessment of cervical and lumbar spine MRIs

T. E. C. D. Sousa[1], L. P. V. Ribeiro[2], A. F. Abrantes[3], A. D. M. Ribeiro[1], S. Rodrigues[3], K. B. Azevedo[3], N. F. Pinto[3], R. P. P. Almeida[3]; [1]Portimão/PT, [2]Parchal/PT, [3]Faro/PT (tiagosousa10@gmail.com)

Purpose: To assess if the image quality from cervical and lumbar spine MRI examinations meets the quality criteria previously established in a radiology department.
Methods and materials: A retrospective study was conducted in a public radiology department using a random sample of 450 cervical and lumbar spine MRI examinations grouped in 15 smaller samples, each one with 30 exams. Using a quality criteria checklist organised into 4 main groups, the conformities and non-conformities found were recorded and used to establish 3 types of quality control chars: the proportion of conformities and non-conformities (p chart), the total number of non-conformity exams (np chart), and the total number of non-conformities in each sample (c chart), in order to suggest corrective actions for improvement.
Results: Considering all exams, 289 were classified as conforming (64.22%) and 171 were classified as non-conforming (38%). Considering the non-conform exams group for the cervical spine, the quality criteria "motion artefacts" presented the highest number of non-conformities (55.56%), followed by "aliasing artefact" (31.11%). For the lumbar spine non-conform exams group, the quality criteria "cross-talk artefact" presented the highest number of non-conformities (45.59%), followed by "aliasing artefact" (21.32%) and "motion artefacts" (20.59%).
Conclusion: The existence of suitable quality control of the image is essential to achieve high-quality standards. Strategies for improving radiographers performance and scientific knowledge must be implemented to ensure that spine MRI examinations are performed in compliance with all the quality criteria established. Therefore, it is essential to implement a checklist for a systematic evaluation based on a quality control program.
Limitations: n/a
Ethics committee approval: The ethics committee approved the study.

A comparison of female pelvic MR image quality: Saudi and Irish perspectives

S. Al Dahery; *Jeddah/SA (shrooq_talal@hotmail.com)*

Purpose: Optimisation of MRI sequences is crucial to ensure high image quality for an accurate diagnosis. The aim is to compare the female pelvic MR image quality acquired from Saudi and Irish MR departments and evaluate the factors impact on it.
Methods and materials: Axial and sagittal T2W MR images were retrospectively collected from (9 Irish; 90 cases) and (10 Saudi; 94 cases) hospitals. Signal intensities of the fundus, gluteus maximus muscle, and the background noise standard deviation were obtained to calculate SNR/CNR. The images were evaluated by 8 expert observers and qualitative evaluation scores were recorded. An intervention was performed to improve image quality in a Saudi centre which had recorded low image quality for several criteria during phase one/two. Resultant images were collected and reviewed.
Results: Variation in the matrix and voxel sizes caused a statistically significant difference in SNR for axial T2W MR images. There was a significant difference in CNR due to the differences in the TR/TE. Statistically significant differences in CNR were recorded for the sagittal images, as the matrix and voxel sizes differed. There was no difference in SNR for sagittal images. Using thinner slices in the uterine T2W sequences resulted in better visualisation of the zonal layers.
Conclusion: A range of currently applied female pelvic MR protocols were identified across Irish and Saudi hospitals which resulted in image quality variations. MR image quality can be optimised by using a robust multi-phase optimisation process as evidenced following the optimisation intervention.
Limitations: The inability to fully explore the impact of patient BMI on image quality.
Ethics committee approval: Exemption from full ethical approval was granted by the Irish Institutional Human Research Ethics Committee and by the relevant IRB in MOH for Saudi hospitals.
Funding: King Abdullah Scholarship.

S. Al Dahery: Speaker at UCD

RPS 1414-4 11:43

Simulated magnetic resonance imaging (MRI) by radiographers to reduce the sedation of paediatric patients

M. Champendal, G. Gullo, L. Marmy; *Lausanne/CH*

Purpose: To develop updated recommendations that are evidence-based to perform simulations as a strategy to prepare paediatric patients for MRI examinations when reducing the use of sedation.
Methods and materials: A systematic review using the Joanna Briggs Institute system for unified management (JBI SUMARI) was performed to identify studies published after 2010. Sedation, anxiety, paediatric*/child, mock MRI/play therapy were included in the search using a 6S model. The databases consulted were National Guidelines Clearinghouse, Nice, HealthEvidence, JBI, Cochrane, Uptodate, Tripdatabase, PubMed, Cinhal, and Google Scholar. 3 independent reviewers assessed articles and Gradepro software was used to rate each recommendation.
Results: 5/266 articles were selected. One was a systematic review, 2 were randomised controlled trials, and 2 were quasi-experimental and observational studies. 2 recommendations graded as B came up: paediatric patients' preparation with an MRI simulation is efficient between 4 and 11 years old. The relative risk of sedation was reduced to almost 50% for patients prepared with a simulated MRI compared to those without preparation. A modified Yale preoperative anxiety scale (mYPAS) test was suggested as a tool to select patients that can be exposed to a simulation when the score is less than 33.
Conclusion: The simulation of an MRI to prepare paediatric patients for this examination is a strategy that can work, but only in specific circumstances and mainly for an age superior to 4 years old. Simulation can reduce anxiety, ensuring a successful examination without sedation. Further studies, however, should be conducted to very if this strategy can be applied to other imaging modalities even using the same simulation setting.
Limitations: Only a few studies were available.
Ethics committee approval: n/a
Funding: No funding was received for this work.

RPS 1414-5 11:49

Technique and protocols for cardiothoracic time-resolved contrast-enhanced MRA sequences: a systematic review

M. Zanardo[1], F. Sardanelli[1], L. A. Rainford[2], C. B. Monti[1], J. G. Murray[2], F. Secchi[1], A. Cradock[2]; [1]Milan/IT, [2]Dublin/IE

Purpose: To review current cardiothoracic applications of time-resolved magnetic resonance angiography (TR-MRA) sequences, focusing on contrast agent (CA) protocols, adopted technical parameters, and acquisition schemes.
Methods and materials: A systematic search of the literature (Medline/EMBASE) was performed in May 2019 to identify articles utilising TR-MRA sequences. The study design, year of publication, population, magnetic field strength, type, dose and injection parameters of CA and injection, and technical parameters of TR-MRA sequences were extracted.
Results: Of 117 retrieved articles, 16 matched the inclusion criteria. The study design was prospective in 9/16 (56%) articles and the study population ranged from 5-185 patients for a total of 506 patients who underwent cardiothoracic TR-MRA. Magnetic field strength was 1.5T in 13/16 (81%) and 3T in 3/16 (19%) articles. The administered CA was gadobutrol (Gadovist) in 6/16 (37%) articles, gadopentetate dimeglumine (Magnevist) in 5/16 (31%), gadobenate dimeglumine (Multihance) in 2/16 (13%), gadodiamide (Omniscan) in 2/16 (13%), and gadofosveset trisodium (AblavarTM) in 1/16 (6%). CA showed highly variable doses among studies: a fixed amount or based on patient body weight (0.02-0.2 mmol/kg) was injected with a flow rate ranging from 1-5 mL/s. Sequences were "TWIST" in 13/16 (81%), "TRICKS" in 2/16 (13%), and "CENTRA" 1/16 articles (6%).
Conclusion: Results identified that a variety of technical approaches were adopted throughout different studies, highlighting a lack of standardisation and consensus. TR-MRA sequences are currently adopted in different clinical settings with different technical approaches, mostly due to different CA dose and type. Further studies are warranted in order to establish appropriate parameters for TR-MRA, especially in relation to CA protocols.
Limitations: No quality assessment was performed in the included studies.
Ethics committee approval: n/a
Funding: No funding was received for this work.

The efficacy of the GRASE sequence compared to the compressed sensing technique for breath-hold three-dimensional MR cholangiopancreatography in patients with hyperintense bile on T1-weighted images

D. Morimoto, T. Hyodo, M. Itou, H. Fukushima, K. Kamata, M. Takenaka, K. Miyagoshi, M. Kudo, K. Ishii*; Osaka-Sayama/JP (morimoto-d@med.kindai.ac.jp)*

Purpose: To compare the image quality of single breath-hold (BH) three-dimensional (3D) MRCP using GRASE with that of the compressed sensing (CS) technique.
Methods and materials: We retrospectively identified 44 patients with hyperintense bile on T1-weighted fat-suppressed images who underwent BH 3D MRCP using both GRASE and CS with a 1.5T scanner. Maximum intensity projection MRCP images were reviewed for visibility of the right, left, and common hepatic duct, common bile duct, gallbladder (GB), cystic duct, and pancreatic duct (PD), motion artefact, background suppression, and overall image quality using a 5-point scale (1=poor; 5=excellent). The scores and availability rates, the latter defined as a visibility score of ≥3, were compared between GRASE and CS using a Wilcoxon signed-rank test and McNemar's test, respectively.
Results: The median visibility scores of each biliary segment were significantly higher in GRASE than CS ($p \leq 0.001$ for all). No significant difference was found for the PD ($p=0.396$). The motion artefact score was not significantly different ($p=0.313$). GRASE had significantly lower background suppression scores ($p<0.001$) and higher overall image quality scores ($p<0.001$) than CS. GRASE had significantly higher rates of availability on the basis of visibility of the GB (44/44 vs 29/44, $p<0.001$) and cystic duct (39/44 vs 19/44, $p=0.001$) than CS. Similar but non-significant trends were observed for the other biliary segments.
Conclusion: BH 3D MRCP with GRASE provides better image quality and higher availability for depiction of the biliary ducts than CS in patients with hyperintense bile on T1-weighted images.
Limitations: Non-consecutive patients might lead to a selection bias.
Ethics committee approval: IRB approval was obtained and informed consent was waived.

The impact of phase-encoding direction on calculated ADC values in DW-MRI of normal bone marrow in the distal femur and proximal tibial

A. Alqattan, A. McGee, E. Delahunt, A. Cradock, S. Eustace, J. McNulty*; Dublin/IE (abrar.alqattan@ucdconnect.ie)*

Purpose: Multiple artefacts can cause variation in the calculated apparent diffusion coefficients (ADCs) for defined anatomical regions, resulting in unreliable quantification in DW MRI. The appropriate selection of parameters and phase-encoding (PE) direction are essential to minimise artefacts. The aim of this preliminary study was to evaluate the impact of PE-orientation on mean ADC for normal bone marrow at sites associated with ACL injury-related bone bruising.
Methods and materials: A standard knee protocol and optimised axial-DWI sequences acquired with the same parameters except for the PE-direction (anterior-posterior (AP) and right-left (RL)) were performed on 15 healthy individuals (18-35 years). For each subject, 30 50mm^2 regions-of-interest (ROIs) were placed on locations associated with ACL-related bone bruising: anterior, medial, and posterior ROIs in the medial and lateral tibial condyles (TC) and medial and lateral femoral condyles (FC). Mean ADC values were calculated and the effect of PE-direction (AP vs RL at b50_600s/mm^{2}and b50_ 800s/mm^2) was evaluated.
Results: The calculated mean ADC for all ROIs with an AP PE-direction was higher than RL PE-direction (diff=0.0066; SE=0.005) for b50_600s/mm^2 and marginally lower (diff=0.0007; SE=0.007) for b50_800s/mm^2. In the FCs, the effect of AP PE-direction was higher than the RL PE-direction by 0.019 (b50_600s/mm^2) and by 0.0398 (b50_800s/mm^2). The mean ADC was marginally lower in (TCs) by -0.005 and -0.025 for both b-value image sets. These results indicate marginal and non-statistically significant differences in mean ADCs for DWIs acquired in two PE-directions (p=0.11).
Conclusion: For healthy volunteers, the use of an AP or RL PE-direction has a minimal impact on ADCs, however, mean ADCs may be affected by changing the PE-direction in subjects with ACL-related bone bruising or ACL reconstructions, which will be evaluated in further research.

Patient satisfaction of the Aspetar MRI service

T. Smith, M. N. A. Mohamed, H. Lloyd, S. Allenjawi, M. Farooq*; Doha/QA (mrinawas@gmail.com)*

Purpose: Patient satisfaction is important as the quality of care directly impacts on the income of health care facilities (Lang et al 2013). Numerous studies on patient satisfaction surveys have been conducted internationally, however, few have focused on MRI services, with virtually no cultural information related to Middle-Eastern populations. From the data collected, we hope to identify areas of weakness in dissatisfaction from our clients. We hope to enhance the image of the radiology department through improved revenue and public positivity.
Methods and materials: After IRB approval, all patients above the age of 18 years who had had an MRI examination were provided with a patient satisfaction survey questionnaire in either Arabic, French, or English. The survey was voluntary and anonymous with 500 surveys taken in a period of 6 months. The questionnaires asked for the patient's demographics, excluding identifiable data, and covered the key factors of competence, communication, sense of confidence, physical environment, and staff demeanour.
Results: There was no significant difference between nationality and satisfaction. The appointment of a scan within 3 days showed a significance in competence, communication, and sense of confidence. Waiting time showed significance in the department's competence, where the best satisfaction was within 15 minutes. For patients who had to wait more than 30 minutes, women were more dissatisfied than men of all participants.
Conclusion: The overall experience with the service of MRI was excellent and 98% would recommend that Aspetar MRI provides the best services and better patient care. Waiting times can impact on patient satisfaction for those who stay more than 15 minutes in waiting areas before proceeding to their scan and this needs to be addressed in the future.
Limitations: n/a
Ethics committee approval: Consent obtained.

Patient perceptions of radiographer communication skills in MRI examinations

R. P. Sousa[1], O. Lesyuk[2], L. P. V. Ribeiro[3], S. Rodrigues[4], R. P. P. Almeida[4], A. F. Abrantes[4], A. D. M. Ribeiro[5]; *[1]Sagres/PT, [2]São Brás de Alportel//PT, [3]Parchal/PT, [4]Faro/PT, [5]Portimão/PT (rpsousa16@gmail.com)*

Purpose: The improvement of results in healthcare through the transmission of information to the patient using empathy and trust is already a verified hypothesis. Healthcare professionals should base themselves on interpersonal competencies throughout their daily work routine to promote quality in medical imaging, patient safety, and technical excellence. The aim of this study was the exploration of the patient's perceptions regarding the performance of

radiographers in terms of interpersonal communication skills during MRI procedures.
Methods and materials: The instrument used was the questionnaire "communication assessment tool" (Makoul et al. 2007) adapted to the professional reality of radiographers. 110 valid questionnaires (including 15 questions with a 5-point Likert scale) from patients aged from 18-85 years old were conducted. The paper-based instrument was delivered and filled by the patients after the performance of MRI procedures in 2 public hospitals.
Results: The internal consistency of the questionnaire was excellent (Cronbach's alpha=0.964). The highest ratings were for radiographer behaviour items, such as "used an accessible language" (4.62), "respect for the patients" (4.58), and "he paid attention to me" (4.53). The lowest ratings were "encouraged to make questions" (3.88), "involved patients in decision-making process" (4.06), and "talk with patients about the next following steps" (3.81).
Conclusion: Radiographers communication skills were evaluated with good levels of patient confidence with the MR examinations. Despite the overall positive results, this area of health service delivery must be accorded the attention it deserves to continually improve patient satisfaction through improved communication.
Limitations: The sample size.
Ethics committee approval: The ethics committee approved the study and written informed consent was obtained.
Funding: No funding was received for this work.

A survey to explore magnetic resonance imaging safety in Greece
N. Stogiannos[1], C. Westbrook[2]; [1]*Corfu/GR,* [2]*Cambridge/UK (nstogiannos@yahoo.com)*

Purpose: To explore specific MRI safety policies in Greece and compare them with the recommendations of the American College of Radiology (ACR). The null hypothesis was that there are no significant differences between the safety policies employed in Greece and the ACR's safety guidelines.
Methods and materials: All the MRI units currently operating in Greece were included in this study. Census sampling method was used. This resulted in a sample size of 307 MR scanners, operating both in a public/private or inpatient/outpatient environment. A specific questionnaire was distributed to the participants, with pre-coded closed questions. Statistical analysis was performed on IBM Spss statistical software, version 24.0. Descriptive statistics were performed to analyse the results. Pearson's Chi-square test was used to measure possible relationships between variables.
Results: Out of 307 MR scanners, 104 valid responses were received. The response rate was 33.87%, while the level of statistical significance was $p<0.05$. The margin of error was 7.9 percentage points at the 95% confidence interval. Cronbach's alpha coefficient was 0.686.
Conclusion: Greek MRI units reported a relatively good level of compliance with the recommendations of the ACR. However, a high lack of MR safe equipment was noticed, as well as some inconsistencies regarding the optimal zoning system. Specific safety measures are recommended to enhance MRI safety in Greece. Further research is needed.
Limitations: The item non-response bias. The generalisation of the results cannot be achieved due to the relatively low response rate.
Ethics committee approval: Written informed consent was obtained. Approval was given from the scientific committees of all public hospitals in line with the Greek legislation.
Funding: No funding was received for this work.
Author Disclosures:

Assessment of MRI safety knowledge and concepts in radiographers and other medical staff
V. M. F. Silva[1], D. Santos[2], A. Santos[2], J. Santos[2]; [1]*Porto/PT,* [2]*Coimbra/PT (vitorsoft@gmail.com)*

Purpose: There are risks and hazards related to MRI examinations. Therefore, it is extremely important to ensure both professionals and patients' protection from MRI risks and hazards. MRI risks and hazards professionals' knowledge is crucial for better practices.
The main purpose was to evaluate the knowledge about MRI safety of radiographers and medical physicians (radiology and neuroradiology), considering their experience, education, and background.
Methods and materials: This study was directed to radiographers and medical physicians working in public, private, and public-private institutions through an online questionnaire with 20 questions. The analysis of the influence of the experience in MRI was made with a Student t-test for independent samples and a Mann-Whitney test. Statistical analysis of the influence of extracurricular formation on MRI was performed using the ANOVA test.
Results: 128 complete replies were obtained, 102 from radiographers, 15 from radiologists, and 3 from neuroradiologists.
It was found that MRI experience and education were statistically significant ($p\leq0.05$) in concerns about MRI safety knowledge when compared to professionals without MRI experience and education.
Conclusion: This study focuses on the impact of continuing education, highlighting the importance of training dedicated to the area of professional performance related to MRI safety.
Limitations: The sample could be bigger.

A comparison of postoperative recurrence evaluation among FDG-PET/MRI, whole-body MRI, FDG-PET/CT, and conventional methods in non-small cell carcinoma patients
Y. Ohno[1], M. Yui[2], K. Aoyagi[2], T. Yoshikawa[3]; [1]*Toyoake/JP,* [2]*Otawara/JP,* [3]*Kobe/JP (yohno@fujita-hu.ac.jp)*

Purpose: To compare the capability for postoperative recurrence evaluation among FDG-PET/MRI, whole-body MRI, FDG-PET/CT, and conventional methods based on guidelines in non-small lung cancer (NSCLC) patients.
Methods and materials: 484 consecutive postoperative NSCLC patients (289 men, 195 women; mean age 69 years) prospectively underwent whole-body MRI, integrated PET/CTs, and conventional radiological methods, as well as a follow-up or pathological examinations. All patients were divided into recurrence (n=42) and non-recurrence (n=442) groups based on pathological and follow-up examinations. All co-registered PET/MRIs were generated by means of our proprietary software. The probability of postoperative recurrence in each patient was visually assessed on all methods by means of a 5-point visual scoring system. To compare diagnostic performance among all methods, receiver operating characteristic analyses were performed. The diagnostic accuracy of postoperative recurrence was statistically compared by using McNemar's test.
Results: The area under the curves (AUCs) of PET/MRI (AUC=0.99) was significantly larger than others (MRI and PET/CT: AUC=0.97, $p<0.05$; conventional methods: AUC=0.94, $p<0.05$). When feasible threshold values were applied, the accuracy of PET/MRI (97.7%) was significantly higher than others (MRI: 96.3%, $p<0.05$; PET/CT: 94.8%, $p<0.05$; conventional methods: 90.0%, $p<0.05$). The accuracy of MRI was significantly higher than PET/CT and conventional methods ($p<0.05$). In addition, the accuracy of PET/CT was significantly higher than conventional methods ($p<0.05$).
Conclusion: FDG-PET/MRI has better the potential for postoperative recurrence evaluation than others in postoperative NSCLC patients.
Limitations: Qualitative visual assessment for postoperative recurrence.
Ethics committee approval: This prospective study was approved by the institutional review board of Kobe University Hospital, and written informed consent was obtained.

Dynamic perfusion area-detector CT (ADCT) versus FDG-PET/CT: the capability for therapeutic outcome prediction in small cell lung cancer patients with limited disease

Y. Ohno[1], Y. Fujisawa[2], K. Fujii[3], N. Sugihara[2], S. Seki[4], T. Yoshikawa[4]; [1]Toyoake/JP, [2]Otawara/JP, [3]Tokyo/JP, [4]Kobe/JP
(yohno@fujita-hu.ac.jp)

Purpose: To directly compare the capability for therapeutic outcome prediction among dynamics contrast-enhanced (CE-) perfusion area-detector CT (ADCT) and FDG-PET/CT in small cell lung cancer (SCLC) patients evaluated as limited disease (LD).
Methods and materials: 43 consecutive and pathologically diagnosed SCLC patients assessed as LD underwent PET/CT, dynamic CE-perfusion ADCT, chemoradiotherapy, and follow-up examination. In each patient, therapeutic outcomes were assessed based on RECIST guideline. All patients were divided into 2 groups as follows: responder (CR+PR: n=33) and non-responder (SD+PD: n=10) groups. The total tumour perfusion (TTP) and tumour perfusions from pulmonary (TPP) and systemic (TPS) circulations calculated by the dual-input maximum slope method from dynamic ADCT data and SUV_{max} were assessed at each targeted lesion. The average value of each index from all targeted lesions was compared between responders and non-responders by Student's t-test. To compare the differentiation capability in the 2 groups, all indexes as having significant difference were assessed by ROC analysis. Differentiation capability was compared among all indexes as having a significant difference between the 2 groups by McNemar's test.
Results: There were significant differences in all indexes except TPP ($p<0.05$). The area under the curve (AUC) of TPS (AUC=0.92) was significantly larger than that of SUV_{max} (AUC=0.73, p=004). When applied, each feasible threshold value and the accuracy of TTP (83.7%) and TPS (93.0%) were significantly higher than that of SUV_{max} (76.7%, $p<0.05$).
Conclusion: Dynamic CE-perfusion ADCT has a better potential for predicting the therapeutic outcome than PET/CT in SCLC patients with limited disease.
Limitations: No comparison of survival.
Ethics committee approval: This prospective study was approved by the institutional review board of Kobe University Hospital and written informed consent was obtained.

Radiological classification of sub-solid lung nodules to differentiate three subtypes of early pulmonary adenocarcinoma

X. Cui[1], M. A. Heuvelmans[1], S. Zheng[1], H. J. M. Groen[1], M. Dorrius[1], M. Oudkerk[1], G. de Bock[1], R. Vliegenthart[1], Z. Ye[2]; [1]Groningen/NL, [2]Tianjin/CN
(cuixiaonan1988@163.com)

Purpose: To design a CT reporting system for the classification of sub-solid lung nodules to differentiate early pulmonary adenocarcinoma subtypes (SSNs) in clinical patients.
Methods and materials: We retrospectively identified 437 SSNs from 2011-2017 with pathological confirmation. SSNs were divided into a training group (N=291) and a testing group (N=146). In multinomial univariable and multivariable logistic regression, CT characteristics were analysed to identify factors discriminating between 3 adenocarcinoma subtypes [pre-invasive lesions (PLs), minimally invasive adenocarcinoma (MIA), and invasive adenocarcinoma (IA)]. The resulting differentiating factors were included in a classification and regression tree (CART) model. Subsequently, a CT reporting system was constructed for SSNs based on the optimised classification model. The classification performance was validated in the testing group.
Results: The most important differentiating factors based on CT-derived characteristics of sub-solid nodules were visual density (non-solid or part-solid), core (present or absent), diameter of solid component (≤6 mm or >6 mm), and semantic features (vacuole sign, pleural indentation, and vascular invasion). Overall sensitivity, specificity, and diagnostic accuracy of CT reporting system were 89.0% (95%CI: 84.8%-92.4%), 74.6% (95%CI: 70.8%-78.1%), and 79.4% (95%CI: 76.5%-82.0%) for the training group, and 84.9% (95%CI: 78.1%-90.3%), 68.5% (95%CI: 62.8%-73.8%), and 74.0% (95%CI: 69.6%-78.0%) in the testing group, respectively.
Conclusion: A CT reporting system for sub-solid pulmonary nodules helps to differentiate 3 adenocarcinoma subtypes. The classification tool can be used to assist clinicians in making follow-up recommendations or decisions with regards to surgery in patients with SSNs.
Limitations: This study is a single-centre retrospective study. The results may be limited to the local population.

RPS 1416a-5 11:33

Preoperative staging of tumours with mediastinal invasion: cine-MRI versus CT in the detection of cardiac and vascular involvement

N. Gennaro, U. Cariboni, F. Fazzari, V. M. Giudici, A. Rossi, O. G. Santonocito, P. Novellis, M. Infante, L. Balzarini, L. Monti; Rozzano/IT
(nicolo.gennaro@st.hunimed.eu)

Purpose: The accurate staging of tumours invading the mediastinum provides surgeons with critical information for patient selection and surgical planning. Contrast-enhanced CT is currently used for presurgical staging.
The aim of the study is to assess whether cine-MRI improves accuracy in the detection of neoplastic infiltration of critical mediastinal vascular and cardiac structures compared to contrast-enhanced CT, thus possibly expanding the spectrum of patient candidates to radical surgery.
Methods and materials: From 2008-2018, 32 patients (17M, 25F, mean age 56±14 years) diagnosed with neoplasms invading the mediastinum (lung cancer, n=16; sarcoma, n=7; thymic tumours, n=6; carcinoid, n=1; teratoma, n=1; germ cell tumours, n=1) underwent both contrast-enhanced CT and ECG-gated cine-MRI for preoperative staging. Imaging studies were reviewed by 2 expert cardio-radiologists.
The presence/site of infiltration of critical (aorta, myocardium, and pulmonary arteries) and non-critical vascular structures were noted and analysed separately. CT and MRI diagnostic performances were assessed using the postoperative anatomopathological report as a reference standard.
Results: Cine-MRI showed better diagnostic accuracy (90.2% vs 70.5%, p=0.03) in the detection of cardiac, aortic, and pulmonary artery involvement compared to CT. MRI excluded invasion of the myocardium and critical vascular structures in 8/32 (23.5%) patients that were initially considered non-surgical candidates according to CT findings.
Conclusion: Cine-MRI is more accurate than contrast-enhanced CT for the pre-operative assessment of mediastinal tumours with extensive contact with the heart or the great vessels. In our series, cine-MRI refined resectability in 23.5% of patients considered as non-surgical candidates according to contrast-enhanced CT findings.
Limitations: The limited number of patients and the unavailability of synchronised-CT studies for comparison with ECG-gated cine-MRI.
Ethics committee approval: ERB approved.
Funding: No funding was received for this work.

Prognostic 18F-FDG PET markers for immune-checkpoint inhibitor therapy in patients with non-small cell lung cancer

D. Kifjak, L. Beer, A. Haug, M. E. Mayerhöfer, M. Hochmair, H. Prosch; *Vienna/AT (daria.kifjak@meduniwien.ac.at)*

Purpose: To identify 18F-FDG-PET-CT quantitative imaging markers for survival in patients with advanced non-small cell lung cancer (NSCLC) treated with PD-1/PD-L1 inhibitors.
Methods and materials: This prospective, single-centre study included 40 patients with NSCLC who underwent 18F-FDG-PET-CT before and 8-12 weeks after the start of treatment with a PD-1/PD-L1 inhibitor. We semi-automatically extracted the following parameters: SUV_{Peak}, TLG (total lesion glycolysis), MTV (metabolic tumour volume), SLR (the spleen-to-Liver ratio), and the bone marrow-to-liver ratio at baseline and the follow-up scan. Each parameter at baseline was dichotomised using the median and percent changes of the parameter were dichotomised using ≤50% reduction as the threshold, respectively. We assessed progression-free survival (PFS) and overall survival using the Kaplan-Meier test and Cox regression analysis.
Results: In the univariate analysis, high baseline TLG (hazard ratio (HR): HR=3.05), MTV (HR=3.05), SLR (HR=2.70) as well as changes in TLG (HR=5.84), SUV_{peak} (HR=7.40) and MTV (HR=3.70) were associated with increased mortality ($p<0.05$). In the multivariate analysis, only the high baseline SLR (adjusted aHR=3.51, p=0.008) and changes in TLG (aHR= 6.90, $p<0.001$) were independently associated with increased mortality. Similarly, these parameters were associated with reduced PFS, while in the multivariate analysis, only changes in TLG were independently associated with reduced PFS (aHR=3.54, p=0.003).
Conclusion: Changes in the metabolically active tumour burden correlate with PFS and overall survival. Increased metabolic activity of the spleen at the start of the therapy is an independent risk factor for mortality.
Limitations: The small sample size and single-centre study. Different PD-1 and PD-1L inhibitors.
Ethics committee approval: Ethics committee approval obtained.

RPS 1416a-8 11:45

The optimisation of the CT window setting to differentiate pre-invasive from invasive sub-solid lung nodules

X. Cui[1], S. Fan[1], M. A. Heuvelmans[2], H. J. M. Groen[2], M. Dorrius[2], M. Oudkerk[2], G. de Bock[2], R. Vliegenthart[2], Z. Ye[1]; *[1]Tianjin/CN, [2]Groningen/NL (cuixiaonan1988@163.com)*

Purpose: To determine the best CT window width setting to differentiate pre-invasive from invasive sub-solid pulmonary nodules.
Methods and materials: We retrospectively identified 437 pathologically confirmed SSNs. A solid lesion component on CT images was regarded as a marker of invasiveness (suggestive of MIA or IA). We used a fixed window level (WL) of 35 Hounsfield units and adjusted the window width (WW) until a solid component became visible. This WW was recorded. The best WW cut-off to distinguish invasive and pre-invasive lesions was based on the receiver operating characteristic curve. This WW was defined as the "core" window width. Sub-solid nodules were subsequently categorised as part-solid or non-solid based on the identification of a solid component on the two WW settings, mediastinal window setting (WW/WL, 350/35 HU) and core window setting. The test characteristics were compared.
Results: 88/437 lung lesions were pre-invasive (17 atypical adenomatous hyperplasias and 71 adenocarcinomas in situ) and 349 were invasive (233 minimally invasive adenocarcinomas and 116 invasive adenocarcinomas). The best WW to detect a solid component in SSNs was 1175 HU with AUC of 0.80. Sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy for invasiveness of the SSN were 51.3%, 84.1%, 92.7%, 30.3%, and 57.9% for normal mediastinal window setting and 87.7%, 60.2%, 89.7%, 55.2%, and 82.2%, respectively, for the new core window setting. Of the 233 MIA lesions, 191 (82.0%) were categorised as part-solid based on the core window setting compared to 72 (32.2%) based on the mediastinal window setting.
Conclusion: A new window setting (WW/WL, 1175/35 HU) outperformed the regular mediastinal window setting (WW/WL, 350/35 HU) for detecting a solid component in SSNs.
Limitations: n/a

CT evaluation of NSCLC treated with PD-1/PD-L1 inhibitors: experience of long term follow-up

M. Porta[1], D. Ippolito[1], C. Talei Franzesi[1], M. S. Capici[1], C. Maino[1], L. Riva[1], S. Sironi[2]; *[1]Monza/IT, [2]Bergamo/IT (m.porta9@campus.unimib.it)*

Purpose: Immunotherapy may lead to atypical patterns of tumour response such as pseudoprogression where an initial appearance of an enlarged lesion is followed by tumour regression due to infiltration and recruitment of various immune cells, such as T or B lymphocytes.
The aim of our study is to evaluate the type of response in patients with advanced stage NSCLC treated with PD-1/PD-L1 inhibitors.
Methods and materials: We retrospectively examined 35 patients with advanced-stage NSCLC (24 adenocarcinomas, 9 squamous cell carcinomas, and 1 undifferentiated carcinoma) treated with PD-1/PD-L1 inhibitors.
All patients underwent CT examination (256-row scanner) every 8 weeks, with a minimum of 3 and maximum of 6 CTs for each one. The images were evaluated using iRECIST criteria and all target lesions were analysed with "Intellispace Portal 10.1" software using the "tumour tracking" application for semi-automatic analysis.
Results: Atypical responses were observed in 12 patients (34%); one of them showed pseudoprogression (3%) while 11 showed dissociated responses (31%). No hyperprogression was identified. Patients with dissociated responses had significantly lower median survival than patients with pseudoprogression or typical response ($p<0.05$). Overall, 11 patients showed progression disease (31%) while 24 patients demonstrated partial response or stable disease (69%).
Conclusion: Our results demonstrated a low incidence of pseudoprogression according to the literature (ranging from 0.6% to 5% for patients with NSCLC treated with PD-1/PD-L1 inhibitors). Therefore, increased the tumour burden will reflect true progression than pseudoprogression in most patients.
Whereas, the still-controversial "dissociated response" showed a high occurrence in our study with a poor prognosis.
Limitations: A retrospective study with low availability of patients with at least 3 comparable CTs.
Ethics committee approval: n/a
Funding: No funding was received for this work.

RPS 1416a-10 11:57

The relationship of FDG and iodine-related parameters in non-small cell lung cancer: the potential benefit of PET/CT with dual-energy CT scan in therapy response monitoring

J. Baxa[1], M. Pesek[1], M. Svaton[1], B. Schmidt[2], M. Sedlmair[2], J. Ferda[1]; *[1]Pilsen/CZ, [2]Forchheim/DE (baxaj@fnplzen.cz)*

Purpose: To assess the relationship of FDG uptake and iodine-related parameters in non-small cell lung cancer (NSCLC) with a focus on the therapy response monitoring and prediction.
Methods and materials: Patients (n=45) with confirmed NSCLC stage IIIB and IV who were not qualified for concomitant chemoradiotherapy were included in the study. FDG-PET/CT using single-source dual-energy CT (DE-CT) was performed for staging and early follow-up (after the 2nd cycle of chemotherapy). The correlation of FDG uptake and iodine-related values was assessed and compared with the therapy response.
Results: A strong correlation was found between volumetric FDG parameters (MTV=metabolic tumour volume and TLG=total lesion glycolysis) and the total iodine uptake (mg) using the Spearman correlation coefficient in staging (r=0.0.874, 0.894) and follow-up (r=0.935, 0.934). We also found a significant correlation of change in these values after 2 cycles of therapy. In the prediction

analysis, we proved a significant correlation of iodine uptake, MTV, and TLG with the outcome, and iodine uptake was found as a possible strong predictor (r=0.711; p<0.0001). The change in iodine uptake after chemotherapy correlated with an early therapy effect (r=0.659; p<0.0001).
Conclusion: Our results suggest possible interchangeability in functional assessment. Iodine uptake and volume metabolic parameters were found as predictors of early therapy effect and could be used for a personal approach in therapy conducting.
Limitations: The number of patients and short follow-up period.
Ethics committee approval: The study was approved by institutional ethics committee and patents signed informed consent.

Pseudo or real progression in advanced lung cancer immunotherapy: just a matter of size?
M. C. Sciandrello, A. Ferraris, D. Tore, A. Carisio, G. Bartoli, A. Depaoli, C. Guarnaccia, M. C. Martina, P. Fonio*; Turin/IT (mariaclotilde.sciandrello@gmail.com)*

Purpose: To evaluate early radiological findings that help to discriminate between pseudoprogression and true disease progression in patients with advanced lung cancer treated with immunotherapy.
Methods and materials: We retrospectively evaluated CT scans of 62 patients with non-small cell lung cancer (NSCLC) treated with PD-1 inhibitor using the iRECIST criteria and considering the invasion of adjacent healthy tissues as a possible predictor of true progression. Patients considered in unconfirmed progressive disease (iUPD) underwent a second CT scan 4-8 weeks after suspected progression.
Results: During follow-up, 39 iUPDs were documented; 23 cases after the first cycle of immunotherapy and 16 later, during treatment. The patients presented different CT scan findings: 4 with new lesions, 28 with an increase in the volume of preexisting lesions, and 7 cases of mixed response were documented. Local aggressive tumour behaviour with an invasion of nearby healthy structures was documented in 5 patients. A restaging CT scan performed 4-8 weeks later confirmed true progression (immune confirmed progressive disease, iCPD) in 36 cases, thus leading to a suspension of immunotherapy. All cases of local aggressive behaviour were confirmed as true progression. Only 3 cases of true pseudoprogression were reported (4.8%).
Conclusion: In our experience, the rate of pseudoprogression did not exceed 5%, which is in line with the literature. In clinical practice, considering local cancer aggressiveness could be a useful criterion to allow a more confident differential diagnosis between pseudo and real progression in addition to dimensional iRECIST criteria. This observation, that should be validated in a larger population, could help in identifying a subgroup of patients at a higher risk of real progression, which might be a useful element for clinical decision making.
Limitations: The poor sample, limited to advanced lung cancer.

A nomogram based on CT images and 3D texture analysis for preoperatively differentiating thymic epithelial tumours
C. Ren*; Shanghai/CN (rencaiyue@163.com)*

Purpose: To develop and validate a nomogram in preoperatively predicting pathological classification for thymic epithelial tumour (TET) patients.
Methods and materials: 172 patients with pathologically confirmed TET were retrospectively analysed. They were randomly divided into a training set (n=120) and a validation set (n=52). Preoperative clinical demographics, CT signs, and texture features of each patient were analysed and predictive models were developed using the lasso regression. The predictive effectiveness of models was evaluated and compared by the AUC and DeLong test. A nomogram based on selected parameters was developed. C-index and calibration plots were formulated to evaluate the reliability and accuracy of the nomogram.
Results: 120 patients with low-risk TET (LTET) (A1, AB, and B1 thymoma) and 72 patients with high-risk TET (HTET) (B2, 3 thymoma, and thymic adenocarcinoma) were enrolled in this study. A clinical model, CT model, texture model, and the combination model were established and the AUCs of the 4 models in differentiating LTET from HTET were 0.64, 0.82, 0.86, and 0.94, respectively. The DeLong test showed the combination model held the highest predictive efficiency (p<0.05). A predictive nomogram was developed by the combination model's 4 independently risk factors. The internal and external validated C-index values for the nomogram were 0.89 and 0.96, respectively. The calibration curves indicated a good consistency for differentiating TET classification.
Conclusion: The nomogram we developed on this basis was verified to have clinical utility and has the potential to assist clinicians in making treatment recommendations for TET patients.
Limitations: The results need to be confirmed by further prospective and multicentric studies.

Dose management capability of digital variance angiography (DVA): a 70% reduction of radiation dose in lower limb angiography
M. Gyánó[1], K. Szigeti[1], S. Osváth[2], J. Kiss[1], C. Csobay-Novák[1], B. Nemes[1]; *[1]Budapest/HU, [2]Budakeszi/HU (mgyanostb@gmail.com)*

Purpose: In previous clinical studies, digital variance angiography (DVA) provided higher SNR and better image quality than digital subtraction angiography (DSA). The observed quality reserve might provide an opportunity for the reduction of radiation exposure in x-ray angiography. Our aim was to evaluate the potential of DVA to reduce x-ray dose in lower limb angiography.
Methods and materials: In this prospective clinical study (OGYÉI2830/2017), we enrolled 30 patients with normal renal function undergoing elective lower limb angiography. We compared the signal-to-noise ratio (SNR) of DSA and DVA image-pairs in three regions (abdominal, femoral, and crural) obtained by the Siemens Extremities Care preset (E, 1.2 Gy/frame) or by a low-dose protocol (R, 0.36 microGy/frame). Visual evaluation of all images was performed by specialists using a 5-grade rating scale. The quality of DSA-E and DVA-R images was also compared.
Results: The SNR of DVA images were consistently higher (2.7-3.1-fold) than the corresponding DSA images. Even DVA-R had better SNR than DSA-E (2.1-fold). Altogether, 256 image-pairs were evaluated. DVA images had a significantly higher Likert-score than the corresponding DSA images (E: 3.90±0.07 vs 3.56±0.08, p<0.05; R: 3.60±0.08 vs 3.29±0.09, p<0.05) but there was no difference between DSA-E and DVA-R (3.56±0.08 vs 3.60±0.08). In 77% of all comparisons, DVA-R had at least as good quality as DSA-E with the following regional differences: abdominal 62%, femoral 74%, and crural 84%.
Conclusion: Our data shows that DVA allows for a very substantial (70%) x-ray dose reduction in lower limb angiography without affecting the quality and diagnostic value of angiograms.
Limitations: A single-centre trial.

Endovascular thromboaspiration in acute superior mesenteric artery thromboembolic occlusion

S. Perissi[1], M. Femia[2], U. G. Rossi[2], P. Rigamonti[2], A. M. Ierardi[3], G. Carrafiello[2], M. Cariati[2]; *[1]Genoa/IT, [2]Milan/IT, [3]Varese/IT*

Purpose: Acute thromboembolic occlusion of the superior mesenteric artery (AMS) is a condition with an unfavourable prognosis. Early diagnosis and timely treatment, either surgical or endovascular, is fundamental to restoring blood flow to the ischaemic intestine and to reduce the possible necrotic bowel tracts. The aim of our work is to describe the management of acute AMS thromboembolic occlusion through endovascular thrombus aspiration.
Methods and materials: We reviewed the charts of 41 patients from 2017-2019 with MD-CT diagnosis of acute AMS thromboembolic occlusion and initial signs of bowel ischemia. 35/41 patients underwent endovascular thrombus aspiration through femoral access, with co-axial technique for the treatment of the AMS trunk and its collateral. In the remaining 6 patients, the same technique was performed with subsequent transcatheter selective thrombolytic therapy (12 hours) for the treatment of small distal branches residual thrombi. A follow-up with MD-CT was performed 15 days after the endovascular procedure.
Results: Technical success was achieved in 39/41 patients (95%) and clinical success in 37/41 (90%). 35/41 patients (85%) had postprocedural patency of the main trunk of the SMA and its distal branches with no bowel resection. 4/41 patients (10%) underwent partial resection of the necrotic intestine. 2/41 patients (5%) died after massive bowel ischemia.
Conclusion: Acute thromboembolic occlusion of SMA is a potentially fatal vascular emergency which requires early diagnosis and rapid restoration of mesenteric blood flow. Percutaneous endovascular revascularisation techniques are a valuable alternative to surgical thrombectomy as a first-line therapy.
Limitations: The potential sources of bias.

A retrograde anterior tibial approach for SFA recanalisation: an alternative to the conventional antegrade technique

G. Falcone[1], F. Fanelli[1], A. Cannavale[2], F. Mondaini[1], E. Casamassima[1], G. Gabbani[1], V. Miele[1]; *[1]Florence/IT, [2]Rome/IT*

Purpose: To report our initial experience on retrograde recanalisation of femoropopliteal occlusions (CTO) through the anterior tibial artery (ATA).
Methods and materials: 33 patients (23 male, mean age 68y) with symptomatic CTO (claudication <50mt, Rutherford class ≥iii) of the femoropopliteal segment (mean length 97.4 ± 3.76 mm) underwent a retrograde approach via ATA. In all cases, antegrade recanalisation was unsuccessful. ATA access was performed under ultrasound guidance using a micropuncture set. Recanalisation of the obstructed segment was performed using a support catheter in combination with a 0.035"/0.018" guidewire. After recanalisation, angioplasty and/or stenting was performed through the femoral approach in a standard way.
Results: Technical success with recanalisation of the CTO segment was achieved in all patients. Endoluminal recanalisation was possible in 31 cases (93.9%), while in 2 patients, subintimal revascularisation (6.1%) was performed. The mean recanalisation time was 11' ± 3' (range 5'-15'). The final treatment was performed with a drug-coated-balloon in 24 patients and a drug-eluting stent in the remaining 9. Haemostasis of the ATA was obtained with balloon inflation (inflation time 3-4 minutes) in 26 cases (78.7%), and manual compression in 7 (21.2%). No complications occurred during or after the procedure. Patency of ATA was assessed by USCD in all patients before discharge and after 30 days.
Conclusion: Retrograde ATA access is a feasible and safe approach for complex femoropopliteal recanalisation. Several advantages are reported in comparison to other retrograde accesses (popliteal, pedal, etc.).
Limitations: The population size.

Percutaneous angioplasty with a drug-coated balloon (DCB-PTA) in femoropopliteal arterial disease

G. Mazzarella, D. Laganà*; Catanzaro/IT (gmazzarella@tim.it)*

Purpose: To evaluate the efficacy and safety of percutaneous angioplasty with DCB-PTA as a therapeutic treatment in femoropopliteal steno-occlusions. We evaluated and compared the primary patency at 12 months of both TASC type A and B lesions and TASC type C and D lesions.
Methods and materials: From May 2016-August 2019, 87 patients (34 TASC A, 38 TASC B, 14 TASC C, and 6 TASC D) were treated. After having crossed the steno-occlusions and pre-dilatation with an uncoated balloon, an angioplasty with a paclitaxel-coated balloon was performed. A computed tomographic angiography (CTA) of the lower limbs was made to plan the treatment, while the results were evaluated with ultrasonography (CDUS) after 1, 3, and 6 months from the procedure, and with a CTA after 1 year.
Results: DCB-PTA was made in our study population without early and late clinically adverse events related to the PTA. During the procedure, no distal embolisms or complications to the access site occurred and in 69 patients an immediate resolution of the lesion was obtained. The primary patency at 12 months for TASC type A and B lesions was 81% with target lesion revascularisation (TLR) in 12 patients, while the primary patency at 12 months for TASC type C and D lesions was of 70% with target lesion revascularisation (TLR) in 6 patients.
Conclusion: DCB-PTA is a convenient therapeutic treatment and shows early and late efficacy in TASC A and B lesions. In contrast, it shows less efficacy in terms of restenosis in TASC type C and D lesions but still represent a good alternative.
Limitations: The experience of a single centre.

The efficacy of different embolisation techniques in relation to the different patterns of arterial bleeding: a retrospective analysis of 83 consecutive cases treated in emergency conditions

G. Bianchi, A. Iacopino, G. Campidoglio, P. Palumbo, A. Pace, M. Varrassi, S. Carducci, A. V. Giordano, C. Masciocchi*; L'Aquila/IT*

Purpose: To assess the efficacy of different embolic endovascular materials used to control acute arterial bleeding caused by traumatic or iatrogenic conditions.
Methods and materials: We retrospectively evaluated 83 patients (age range 14-81 years) who underwent embolisation procedures in emergency conditions to control acute abdominal bleedings. Technical success, recurrency rate, and complications were assessed in relation to the pattern of arterial bleeding and to the different embolisation techniques and materials (coils, glue, gel foam, covered stents, and plugs).
Results: The majority of cases were traumatic and iatrogenic bleeding, respectively, 30 and 42 patients ($p<0.001$). The most frequent bleeding patterns were blush in 75% of cases (single or multiple), pseudoaneurysms (15%), pseudoaneurysms with fistulisation (5%), and oozing bleeding (5%). Technical success was 99% for all the procedures. Treatment failures occurred in complex arterial bleeding patterns (pseudoaneurysms and pseudoaneurysms with fistulisation). In 1% of cases, a subsequent embolisation was necessary. In general, the complication rate was less than 1%.
Conclusion: Arterial bleeding is potentially life-threatening and can be treated with interventional angiographic techniques. Technical success, low recurrency rate, and a low percentage of complications are related to appropriate procedural planning. Our study demonstrates the efficacy of many embolic endovascular materials in controlling different patterns of bleeding. A multidisciplinary approach is essential, as well as the integration and review of laboratory data and other imaging studies.

Limitations: A small sample size.

RPS 1409b-6 11:55

Texture analysis of an arterial graft thrombus on CT angiography: does it correlate with the age of the thrombus and can it predict the success of catheter-directed thrombolysis?

A. K. Verma[1], R. Thornhill[2], S. Ryan[2], A. Hadziomerovic[2], K. R. Smyth[2], G. French[2], A. Gupta[2]; [1]*Lucknow/IN,* [2]*Ottawa/CA*
(drverma.gilbert25@gmail.com)

Purpose: To characterise a graft thrombus using quantitative texture analysis on CT angiography in relation to the thrombus age and clinical profile of a patient and its implication on catheter-directed thrombolysis
Methods and materials: This retrospective study included 67 patients with thrombotic grafts occlusion of the lower extremities referred for catheter-directed thrombolysis. Selected images from pre-procedure CT angiograms were retrieved in a defined study interval, de-identified and assigning each a unique identifier. The clinical data was collected and thrombolysis angiograms from PACS were reviewed for dose of tPA, complications, and the final result.
Thrombi on pre-procedure CTAs were manually segmented and saved as regions-of-interest for subsequent texture analysis. Various textural features were extracted for each ROI. The relationship between each textural feature and (a) the clinical age of the thrombus, (b) the dose of tPA administered, and (c) thrombolysis response (as TIMI grade flow) was explored using Spearman's rho correlation coefficients.
Results: The clinical age of the thrombus was positively correlated with grey-level skewness [p=0.0085], angular second moment [p=0.0031], and negatively correlated with sum entropy, entropy, and both run-level and grey-level non-uniformity.
tPA doses adjusted for the length of the graft segment thrombosed have a positive correlation with the mean grey-level, entropy, difference entropy, as well as both run-level and grey-level non-uniformity. It has a negative correlation with the angular second moment, suggesting decreased grey-level homogeneity associated with larger doses of tPA required.
Textural features were not significantly related to post thrombolysis flow across the re-canalised segment calculated as TIMI grade flow.
Conclusion: CT texture analysis features can be used to predict the age of the graft thrombi as well as the tPA dose required per cm length of the thrombosed graft.
Limitations: A single-centre study.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

Non-contrast-enhanced magnetic resonance imaging for the visualisation and quantification of an endovascular aortic prosthesis, their endoleaks, and aneurysm sacs at 1.5T

M. Salehi Ravesh[1], P. Langguth[1], J. A. Pfarr[1], I. Koktzoglou[2], R. Edelmann[3], J. Graessner[4], O. Jansen[1], J.-B. Hövener[1], J. P. Schaefer[1]; [1]*Kiel/DE,* [2]*Evanston/US,* [3]*Illinois/US,* [4]*Hamburg/DE (Mona.SalehiRavesh@uksh.de)*

Purpose: After an endovascular aortic aneurysm repair (EVAR), a follow-up at 1, 6, and 12 months is recommended for the remainder of the patient's life. The diagnostic standard methods for diagnosing endoleaks and the visualisation of aneurysms in EVAR-patients are invasive digital subtraction angiography (DSA), contrast-enhanced (CE) computed tomographic angiography (CE-CTA), and magnetic resonance angiography (CE-MRA). These techniques, however, require the use of iodine- or gadolinium-based contrast agents with rare, but possibly life-threatening side-effects such as renal impairment, thyrotoxicosis and allergic reactions, nephrogenic systemic fibrosis, and cerebral gadolinium deposition. The aim of this prospective study was to compare a non-contrast-enhanced MRI protocol (consisting of four MRI methods) with DSA and CE-CTA for the visualisation and quantification of an endovascular aortic prosthesis, their endoleaks, and aneurysms.
Methods and materials: 8 patients (mean age 76.8 ± 4.9 years, 63% male), whose thoracic, abdominal, or iliac aneurysms were treated with a different endovascular prosthesis and suffered from type I-V endoleaks were examined on a 1.5 Tesla MR system. Quiescent-interval slice selective MR angiography (QISS-MRA), 4-dimensional (4D)-flow MRI, T1- and T2-mapping, and DSA and CE-CTA were used for the visualisation and quantification of the endoprosthesis, endoleaks, and aneurysms in these patients.
Results: QISS-MRA provided good visualisation of endoleaks and comparable quantification of the aneurysm size with respect to CE-CTA and DSA. The 4D-flow MRI provided additional information about the wall shear stress, which could not be determined using DSA. In contrast to CE-CTA, T1- and T2-mapping provided detailed information about heterogeneous areas within an aneurysm sac.
Conclusion: Compared to DSA and CE-CTA, the proposed MRI methods provide improved anatomical and functional information for various types of endoprostheses and endoleaks.
Limitations: The small number of patients.
Ethics committee approval: No. D 517/18.

Risk factors for macroembolisation in femoropopliteal interventions using the SpiderFX filter embolic protection device

K. M. Treitl, M. Czihal, M. Treitl; *Munich/DE*
(karlamaria.treitl@med.uni-muenchen.de)

Purpose: To assess the safety and efficacy of a filter embolic protection device (FEPD) in the treatment of femoropopliteal peripheral arterial occlusive disease (PAOD).
Methods and materials: The monocentric retrospective study included 244 cases (mean age 71.4 ± 10.9 years; mean lesion length 13.2 ± 12.9 cm; 60.4%/39.6% Fontaine stage II/III-VI) in which a FEPD was used during recanalisation. The clinical outcome and FEPD-related complications (retrieval/placement/vasospasm/peripheral embolisation) were assessed. The degree of filter filling was semi-quantitatively classified (5-point-scale) and risk factors for filter macroembolisation (FME; grade 4 and 5) were calculated by multivariate analysis.
Results: Balloon angioplasty ± stenting (BAP), directional atherectomy ± BAP ± stenting (DA), and rotational thrombectomy ± BAP ± stenting (RT) were performed in 141, 61, and 42 cases, respectively. Revascularisation was successful in 96.7%. FEPD placement and retrieval failed in one case each (0.4%). Vasospasm requiring medical spasmolysis, peripheral embolisation, and FME occurred in 11, 10, and 91 cases, resulting in FEPD-related complication rates of 4.5%, 4.1%, and 37.3%, respectively. Peripheral embolisation and FME were more frequent in the BAP- and RT-groups (BAP: 4.9%/36.2%; RT: 4.8%/47.7%; DA: 1.6%/32.8%). Total occlusion, lesion length>19 cm, visible thrombus, atherectomy, and diabetes mellitus were identified as risk factors for FME after BAP and DA.
Conclusion: The FEPD is safe and efficient in capturing embolic debris during recanalisation in femoropopliteal PAOD, but a residual risk of embolisation remains, especially in RT.
Limitations: n/a
Ethics committee approval: The study protocol followed the principles of the Declaration of Helsinki and was approved by the institutional ethical review board. The indication for endovascular treatment was determined in an interdisciplinary consensus conference according to the current national guidelines. Written informed consent was obtained.

Endovascular limb revascularisation in no-option critical limb ischaemia: distal deep foot vein arterialisation
G. Cangiano[1], M. Silvestre[2], F. Pane[2], A. Borzelli[2], M. Coppola[2], A. Paladini[3], F. Corvino[2], F. Amodio[2], R. Niola[2]; [1]*San Sebastiano al Vesuvio/IT,* [2]*Naples/IT,* [3]*Novara/IT (kekkopane@hotmail.it)*

Purpose: To describe our experience in treating no-option critical limb ischaemia patients employing endovascular techniques for distal deep venous arterialisation.
Methods and materials: We retrospectively reviewed 16 patients between 2016-2018 (11 M, 5F; mean age 65 years) not eligible for surgical or endovascular approaches for revascularisation and major amputation candidates. After several failed attempts of standard or alternative intraluminal arterial recanalisation, we tried a subintimal approach using a 0.014 inch and 300 cm-long guidewire supported by a 2×40 mm low-profile balloon catheter. Taking advantage of the presence of heavy calcification in the distal portion of the foot artery, we intentionally pursued entry into a distal vein from a subintimal channel through the artery. In case of failure, we attempted the creation of an iatrogenic fistula with a pioneer plus catheter after we placed covered stents to ensure its patency.
Results: In 10 patients, we were able to revascularise the foot with the first technique, in 6 patients we performed the second one. In one case, it was necessary to embolise a collateral vein which was stealing arterial blood from the angiosomic target. Major amputation was observed in one patient. In two cases, we had minor amputations. In 11 cases, we achieved successful wound healing during 6 month follow-up after the procedures. In 81% of patients (13/16), we observed 3-month-fistula patency. One patient died due to other cardiovascular reasons.
Conclusion: Distal deep venous arterialisation proved to be an effective, safe, and promising technique to improve recanalisation rates and limb salvage in no-options critical limb ischaemia patients. However, we need further trials and investigations to improve the rate of success and employ it safely in daily clinical practice.
Limitations: A small sample.

RPS 1409b-10 12:19
Postpancreatectomy haemorrhage (PPH) after pancreaticoduodenectomy (PD): what is the role of interventional radiology (IR)?
D. Palumbo[1], G. Guazzarotti[1], S. Gusmini[1], P. Marra[2], M. Salvioni[1], M. Venturini[1], F. de Cobelli[1]; [1]*Milan/IT,* [2]*Bergamo/IT*

Purpose: To evaluate the role of IR in the diagnosis and management of PPH.
Methods and materials: From 01/2015-05/2019, 656 patients underwent PD. PPH has been classified on the basis of bleeding onset (early if within 24 hours after surgery; delayed when occurring later) and severity (mild or severe according to the amount of blood loss and transfusion requirements) into three grades according to 2007 ISGPS classification.
The source of bleeding, bleeding pattern, type of material used for embolisation, and technical success have been systematically recorded for each PPH.
Results: 58 (8.8%) patients had at least one PPH episode, for a total of 70 PPH (6 early grade b, 14 late grade b, and 50 grade c). Early PPH patients underwent upfront surgery, whereas late PPH episodes were first evaluated with CT scan. Late grade b were then treated conservatively and late grade c all underwent IR procedures.
In this subset, diagnostic angiography revealed the bleeding source in 47/50 (94%) cases (gastroduodenal [15/50, 30%], hepatic [14/50, 28%], superior mesenteric [14/50, 28%], inferior epigastric [2/50, 4%], and dorsal pancreatic artery [2/50, 4%]).
We observed active bleeding in 28 cases (56%), pseudoaneurysms in 21 (42%), and irregular vessels in 16 (32%).
IR permitted an efficient treatment of PPH in 46/47 cases with positive diagnostic angiography (technical success: 97.8%) using, sometimes in combination, covered stent (22/46, 47.8%), coil (21/46, 45.6%), and embolising particles or cyanoacrylic glue (13/46, 28.3%).
Conclusion: IR has a fundamental role in the diagnosis and treatment of PPH, in particular of grade c PPH.
Limitations: The need for prospective validation.
Ethics committee approval: Patients' consent was collected according to the ethics committee requirements in all those who had previously signed a procedure-specific informed consent covering retrospective studies.
Funding: No funding was received for this work.

Type II endoleak: go straight!
G. Falcone[1], F. Fanelli[1], A. Cannavale[2], E. Chisci[1], M. Citone[1], S. Michelagnoli[1], V. Miele[1]; [1]*Florence/IT,* [2]*Rome/IT*

Purpose: Type II endoleaks represent the most common complication after endovascular aortic aneurysm repair (EVAR).
Methods and materials: 50 patients, 31 male, with post-EVAR type-II endoleak underwent percutaneous direct sac puncture. The procedures were performed under local anaesthesia.
Sac puncture was done using a 20G needle under rotational-angiography guidance. A coaxial system (4Fr catheter+2.7 microcatheter) was used to navigate within the sac. During the follow-up period, all patients underwent contrast-enhanced ultrasound (CEUS) at 6 and 12 months.
Results: Technical success with complete embolisation of the aneurysmatic sac was achieved in all cases. No complications, correlated to the direct percutaneous sac puncture, or to Onyx injection, occurred. The time of the procedure varied between 36 and 68 minutes (mean 51.36 minutes). The mean fluoroscopy time was 16.7 minutes. Posterior left access was used in 41 cases, posterior right access in 6 cases, and an anterior approach in 3 cases. In 19 cases (38%), one or more feeding vessels were visualised and embolised. Sac embolisation was achieved using Onyx+microcoils in 31 cases (62 %) and Onyx alone in 19 cases (38%). The mean amount of Onyx was 4.5 cc. After a 1-year follow-up, 34 cases (68%) of sac shrinkage were reported and in 16 patients (32%), the sac diameter remained stable.
Conclusion: Direct sac embolisation using Onyx, in combination with or without microcoils represents a safe and valid technique to solve type II endoleaks.
Limitations: The population size.

A new MR scoring system for pelvic endometriosis: a feasibility study
S. Kitai[1], A. Tamura[1], Y. O. Tanaka[1], Y. Ota[2], H. Kobori[3], R. Konno[4], R. Shiokawa[1], N. Okada[1], A. Nishimoto-Kakiuchi[1]; [1]*Tokyo/JP,* [2]*Kurashiki/JP,* [3]*Soka/JP,* [4]*Saitama/JP (kitai@jikei.ac.jp)*

Purpose: The revised classification of endometriosis by the American Society for Reproductive Medicine was widely used in evaluating pelvic endometriosis. However, it was not well correlated to the severity of symptoms and obstetrical outcomes as it heavily depended on the size of the ovarian endometriotic cyst. Some trials had been made to make classifications reflecting clinical importance. However, there is no widely accepted system to date. The purpose of this study is to establish a new evaluation scale for the severity of pelvic endometriosis, including adhesion and deeply infiltrating endometriosis (DIE), which are more clinically meaningful.
Methods and materials: 60 cases with pelvic endometriosis were retrospectively evaluated using the same scoring system with MR and laparoscopy, independently. Three radiologists evaluated MR images including sagittal and axial T1-, T2-, and fat-saturated T1-weighted images obtained with 1.5T superconducting MR systems. Two gynaecologists also evaluated recorded video during laparoscopic surgery. Both decisions were made by consensus reading. The score included adhesions between uterus and bladder, uterus and ovaries, uterus and rectum, ovaries and rectum, and bilateral ovaries and fibrotic plaque on the posterior uterine aspect, respectively. The Pearson's coefficient of correlation of the total score between MR and laparoscopy was calculated. We also studied the concordance rate of each score.
Results: The Spearman's rank correlation coefficient between the MR and laparoscopy was 0.81. The concordance rate of each score was 0.52-0.97.
Conclusion: Our new MR scoring system emphasised adhesion and DIE was feasible to evaluate the severity of endometriosis.
Limitations:
A limited number of cases.

RPS 1407b-2 11:31

Non-inferiority analysis of endometriomas using DIXON sequence in comparison with conventional pre-contrast volumetric T1 (VT1) sequence

M. M. Filisbino[1], F. H. C. Souza[1], L. E. Paiva[1], M. D. P. Estrela[2], D. M. D. Araújo[1], A. Skaf[1], H. M. L. Filho[1]; [1]São Paulo/BR, [2]Barretos/BR *(marianamarins2810@hotmail.com)*

Purpose: To assess the non-inferiority of a DIXON sequence (DiS) in relation to VT1 in endometrioma evaluation, between readers, using subjective and quantitative analysis.
Methods and materials: 100 consecutive MRIs performed between April 2016-April 2018 were evaluated, half with the word endometriomas in the report and half with normal exams.
The exams were randomly distributed to two readers, a fellow with one year experience and a junior radiologist with 3 years of experience in pelvic imaging. The readers did two sessions: first, they were instructed to look only at DiS, and second, after a month interval to reduce memory bias, only at the VT1 sequence. The following criteria were evaluated: the presence of an endometrioma, size, signal ratio (SR), and laterality.
The SR was assessed with a region of interest (ROI) placed in the lesion and in the ipsilateral vertebral musculature.
Results: Of the 50 endometriomas cases, 3 were excluded due to incomplete data.
The agreement was perfect between readers in the 50 cases without endometriomas.
The intraobserver agreement was 96.9% for the first reader and 92.8% for the second, with kappa (k) values of 0.94 and 0.85, respectively. Interobserver agreement was 94.9% using VT1 and 92.8% for the DiS, with k values of 0.89 and 0.85, respectively.
The signal ratio was 1.78 using DiS and 2.05 for VT1, with p value=0.005.
Conclusion: The DIXON sequence is effective as the conventional T1 sequence for the evaluation of endometriomas, showing good agreement between observers, even without a higher signal ratio, as we postulated previously.
Limitations: A small sample and single institution.
Ethics committee approval: n/a
Funding: No funding was received for this work.

MR classification of deep pelvic endometriosis: description and impact on surgical management

S. Lamrabet, A. Crestani, A. Bekhouche, C. Owen, C. Touboul, E. Darai, I. Thomassin; *Paris/FR (samia.lamrabet@gmail.com)*

Purpose: To retrospectively test the performance and reproducibility of MR Enzian classification and to develop a new MR classification, including lateral endometriosis, and to evaluate their ability to predict postoperative complications.
Methods and materials: Between 2017/01/01 and 2018/12/31, 150 women (mean age 34,5 years, 20-52 years) with deep endometriosis (DE) at MR imaging with a subsequent surgery were recruited. Two radiologists (junior and senior) independently reviewed MR images and rated DE according to MR Enzian classification and a new radiological classification named deep pelvic endometriosis index (dPEI), grading the severity of DE in low (≤2 compartments), moderate (3 or 4 compartments), and high extensive (≥5 compartments).
Results: MR and surgical Enzian classification were concordant for A lesions in 78.7% (118/150), for B lesions in 34.7% (52/150), and for C lesions in 82.7% (124/150). Operative time and hospital stay were longer in A2 compared to A0, B2 to B0, C3 to C2, and C2 to C0 ($p<0.001$) in high extensive compared to moderate extensive DE, and in moderate to low extensive DE ($p<0.01$). Patients with a vagina or rectosigmoid involvement had, respectively, 6 and 3 times more frequent complications according to Clavien Dindo ($p<0.001$). Postoperative dysuria was correlated to the presence of A lesions (OR=6.82, p=0.001), parametrial lesions (OR=6.6, p=0.0002), a moderate or high extensive DE according to dPEI (OR=4.15, p=0.001), unilateral lateral pelvic involvement (OR=3.6, p=0.03), and C lesions (OR= 2.6, p=0.04).
Conclusion: MR imaging is accurate to predict postoperative complications, helping clinicians to preoperatively inform patients of the specific risk of surgery for DE.
Limitations: A highly experienced centre. No long term follow up.
Ethics committee approval: Our institutional ethics committees approved the study and granted a waiver of informed consent.
Funding: No funding was received for this work.

Minimal endometriosis: is it a valid MRI diagnosis? A retrospective correlation study between readers with distinct expertise levels

H. Leao Filho, E. Soares Souza, M. Figueiredo Alves, M. Sousa Castro, A. Skaff; *São Paulo/BR (hiltonmlf@gmail.com)*

Purpose: With increasing MRI usage for female pelvic pain evaluation, we are seeing an increase of minimal deep endometriosis diagnosis showing very subtle/subjective findings.
The study's purpose was to evaluate subtle/minimal endometriosis findings on MRI, assessing inter and intraobserver concordance between radiologists with different expertise levels.
Methods and materials: We conducted a retrospective study selecting 100 female pelvic MRI exams from 2015-2018. We searched for 50 normal MRI reports and 50 other examinations were chosen using keywords describing incipient/subtle endometriosis in the radiology reports.
The MRIs were independently analysed by three radiologists with different experience levels (two assistants with 15 and 3 years of expertise and one fellow with 1 year of expertise). They were blinded to clinical data and original reports. The readers filled a questionnaire determining the presence (or absence) and location of pelvic endometriosis. After a 2 months interval (memory bias), all the

readers re-evaluate the exams. The imaging criteria was revised with all the readers with practical cases before the study started.
Results: The intraobserver analysis was poor or weak in most compartments, with kappa (k) values varying between 0.24-0.48 for torus uterinus (TU-mean: 0.37) and 0.21-0.41 for utero-sacral ligaments (USL-mean: 0.36). The other areas reached lower k values, with the exception of ovaries (mean: 0.62).
The interobserver analysis was also low, with intraclass correlation values of 0.039 for TU and 0.032 for USL. Even if the studies were analysed by the presence of at least one area positive, the ICC was also poor, reaching 0.018.
Conclusion: Inter and intraobserver agreement were poor for assessing subtle/minimal endometriosis with pelvic MRI. These findings were independent of the reader's experience level.
Limitations: A single-centre study with a small number of patients and no pathological confirmation.
Ethics committee approval: Ethics approval, informed consent waived.
Funding: No funding was received for this work.

Role of preoperative transvaginal ultrasound mapping in the surgical management of deep infiltrating endometriosis: a prospective study
S. M. M. M. M. El-Maadawy, C. Nagy*; Dubai/AE (samarmaadawy@gmail.com)*

Purpose: To assess the accuracy of a new transvaginal ultrasound (TVS) mapping system in defining the size and location of deep infiltrating endometriosis (DIE) with laparoscopic and histologic confirmation.
Methods and materials: Our study included 51 patients showing features of DIE by TVS with subsequent laparoscopic and histologic evaluation. Data was collected from October 2017 to September 2019. All patients were examined by the same radiologist with GE E8 (GE Healthcare) ultrasound machine using a transvaginal 5-9 MHz transducer. Conventional 2D and 3D volume acquisition using volume contrast imaging (VCI) and tomographic ultrasound imaging (TUI) was used. Accurate mapping of the extent of DIE was recorded using a dedicated mapping sheet during TVS by the radiologist and at laparoscopy by the same surgeon who was blinded to TVS mapping. Results were correlated with histopathology findings.
Results: Laparoscopy detected DIE in all 51 patients. Depending on the locations of DIE, the accuracy of TVS ranged from 73%-98%. The lowest sensitivity (47%) and accuracy (73%) was seen in a TVS diagnosis of vaginal DIE with a positive likelihood ratio (LR+) of 2.8, while the highest accuracy (98%) was seen in detecting bladder lesions with LR+ of 47. 5 cases showed additional scar endometriosis with 100% accuracy.
Conclusion: We believe that the new TVS mapping is accurate in detecting the extent of DIE, which may help in preoperative evaluation and intraoperative management to tailor the surgical approach, thus improving patient outcomes.
Limitations: The high incidence of DIE in the sample due to patient selection and setting of the study as a referral centre for endometriosis.
Ethics committee approval: Informed consent was obtained from all patients.
Funding: No funding was received for this work.

RPS 1407b-6 11:55
Benign or malignant endometrium: can functional MRI techniques like diffusion-weighted magnetic resonance imaging (DW-MRI) and dynamic contrast-enhanced (DCE-MR) help us in differentiation?
M. Gulati, A. Garg, R. Dixit, G. Gandhi, N. Khurana*; New Delhi/IN (gulati_malvika92@yahoo.com)*

Purpose: To compare findings of conventional MRI, DWI, and DCE-MRI in benign and malignant endometrial lesions.
Methods and materials: 44 adult female patients with sonographically suspected endometrial lesions underwent MR imaging of the abdomen and pelvis (T1, T2WI, DWI, and DCE MRI). Conventional MR images were analysed for morphological features. The presence or absence of restricted diffusion was assessed on DWI and ADC values were calculated. Using DCE images, enhancement characteristics were studied and time-signal intensity (TIC) curves were generated. Appropriate tests for statistical analysis were applied. The ROC curve was applied to determine the ADC threshold value to differentiate between the malignant and benign lesions. The imaging diagnosis was finally compared with histopathological examination or follow-up imaging.
Results: Of 44 patients, 16 had benign lesions and 28 harboured malignant lesions. Conventional MR findings found to have a significantly higher frequency in benign lesions were a brightly hyperintense signal on T2WI, smooth tumour/endo-myometrial interface, and the presence of well-defined cystic areas within the mass ($p<0.01$). Diffusion restriction was seen only in 2/16 benign cases, however, was demonstrated in all the malignant cases ($p<0.01$). Using a ROC curve, cut off ADC value of $<0.859 \times 10^{-3}$ mm^2/sec was seen to have a sensitivity, specificity, PPV, and NPV of 100%, 89.3%, 100%, and 93.2%, respectively, for predicting malignant endometrial lesions. On dynamic imaging and TIC analysis, the increasing trend of enhancement was found to have a sensitivity of 86.2% and specificity of 81.2% for benign lesions.
Conclusion: Newer functional MR techniques of DWI and DCE-MR can significantly add to conventional MR imaging in differentiating benign from malignant endometrial lesions.
Limitations: A small sample size.
Ethics committee approval: Approval from an institutional ethical committee obtained.
Funding: No funding was received for this work.

Multiple-b values of diffusion-weighted imaging (DWI) for grading endometrial cancer
O. Zhang, X. Zhao, H. Ouyang*; Beijing/CN (18810683722@163.com)*

Purpose: To investigate multiple-b value DWI derived parameters in assessing the pathological grade of endometrial cancer (EC) preoperatively.
Methods and materials: 43 consecutive patients with EC confirmed by pathology underwent multiple-b value DWI with 13 b values on a 3.0T MR scanner preoperatively. Multiple-b value DWI derived parameters, including apparent diffusion coefficient (ADC), true diffusivity (D), perfusion-related diffusivity (D*), and perfusion fraction (f), were measured by two radiologists independently and were compared between three groups identified by three histological grades by using the ANOVA. After combining G1 and 2 groups, a binary logistic regression model was used to calculate the the predictive probability of combined parameters indicating statistical significance in identifying high-grade EC. ROC curve was employed to determine the diagnostic efficiency of these parameters.
Results: Significant differences of ADC and D values were found between G1 and G3 (P=0.001 and 0.010), between G2 and G3 of EC (P=0.009 and 0.025), while f values were significantly lower in G3 than those in G1 (P=0.010). There was no significant difference of D* between those three groups. The largest AUC was observed by using ADC to distinguish G3 from G1-2 (AUC=0.825). Moreover, the combined parameter showed better diagnostic performance and the combination of D and f values had the highest AUC in the prediction of high-grade EC (AUC: 0.828). With the cut-off larger than 0.289, the sensitivity and specificity were 85.7% and 72.4%, respectively.
Conclusion: Multiple-b value DWI derived parameters could provide additional information for grading EC, which could be helpful in treatment planning and prognosis evaluation.
Limitations: We performed 13 b values for a multiple-b value DWI protocol which prolonged the scan time.
Ethics committee approval: Review board approval and written informed consent obtained.
Funding: No funding was received for this work.

Three-dimensional turbo-spin-echo amide proton transfer MR imaging for type I endometrial carcinoma: correlation with Ki-67 proliferation status
Y. He, C. Lin, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. Jin*; Beijing/CN (ylhe_526@163.com)*

Purpose: To evaluate the utility of 3-dimensional amide proton transfer-weighted (APTw) imaging for type I endometrial carcinoma (EC) and the correlation with the Ki-67 labelling index.
Methods and materials: 54 consecutive patients suspected of endometrial lesions underwent APTw and IVIM imaging on a 3T MR scanner. APT values, calculated based on the asymmetry of the acquired Z-spectrum with respect to water frequency, using 3D TSE volume acquisition with B0 correction, were independently measured by two radiologists on 22 postoperative pathological confirmed type I EC lesions as well as IVIM-derived parameters (Dt, D*, f). A Student's t-test and Mann-Whitney U test were used to compare the differences of APT values and IVIM-derived parameters between different histological grades and Ki-67 proliferation groups. ROC analysis was performed. Pearson's

correlation analysis was performed between the APT values, IVIM-derived parameters, and Ki-67 labelling index.
Results: APT values of Ki-67 low-proliferation group (<30%, n=8) were 2.466 ± 0.191, significantly lower than the high-proliferation group (>30%, n=14) with APT values of 3.093 ± 0.142 (p=0.016). AUC was 0.768. The APT values of type I EC were moderately positively correlated with Ki- 67 labelling index (r=0.583, p=0.004). There were no significant difference of D_t (p=0.843), D*(p=0.262), and f(p=0.553) between the low-proliferation group and high-proliferation group. No correlation was found between IVIM-derived parameters and Ki-67 labelling index (D_t, p=0.717; D* p=0.151; f, p=0.153).
Conclusion: 3D TSE APTw imaging is feasible in type I endometrial carcinomas. APT values positively moderately correlate with Ki-67 proliferation status.
Limitations: The sample size was small. We selected the single largest area, not the whole volume, of EEA for APT values measurement.
Ethics committee approval: Approved by our institutional review board. Written informed consent was obtained.

Myometrial invasion by endometrial carcinoma: which sequence is more useful with 3.0 Tesla imaging
L. Karaca[1], A. Sağir Kahraman[1], Z. Ozdemir[1], E. Yılmaz[1], A. Akatlı[1], G. Mert Dogan (balaban)[2], H. Kural[1]; [1]*Malatya/TR*, [2]*Izmir/TR*
(karacaleyla4@gmail.com)

Purpose: To investigate the different sequences of 3 Tesla magnetic resonance imaging and histopathological analysis in assessing myometrial invasion in endometrial carcinoma.
Methods and materials: In this prospective study, 61 women with diagnosed endometrial cancer were examined using 3 Tesla MR and hysterectomy; histopathologic was examined. MRI protocol included DWI, T2-weighted images, dynamic contrast T1-weighted images, and zoom it DWI. Apparent diffusion coefficient (ADC) maps were also obtained. ADC was calculated using both DWI and zoom it DWI.
All series images were examined by endometrium distance to explain myometrial invasion. Histopathological confirmation was conducted following a hysterectomy.
Results: All sequences and histopathological results were compared with the paired sample t-test. There was no significant difference between diffusion and zoom it diffusion to evaluate invasion deep.
In assessing the depth of myometrial invasion, there was a high correlation between histopathological results and both sequences (0.940). Zoom it DWI sequences provided more precise assessment than other T1-weighted image and T2-weighted image sequences.
When all sequences were evaluated, dynamic T1-weighted contrast images were the most inconsistent with pathological results.
Conclusion: In the evaluation of the depth of myometrial invasion by endometrial carcinoma 3 Tesla MR imaging and zoom it, DWI has more value than other conventional sequences.
Limitations: Our study is limited by the relatively small number of patients. In addition, the reader knew the diagnosis of endometrial carcinoma.

A machine learning-based approach for predicting the malignant potential of T2-hyperintense mesenchymal and mixed tumours of the uterus by fusing T2WI features and clinical information
T. Wang, W. Peng, J. Gong; *Shanghai/CN*
(wangtt_shca@126.com)

Purpose: To develop a machine-learning method to predict the malignant potential of T2-hyperintense uterine mesenchymal and mixed tumours by fusing T2WI features and clinical information.
Methods and materials: This retrospective study enrolled 141 patients with T2-hyperintense uterine mesenchymal and mixed tumours (111 patients in the training cohort and 30 in the validation cohort). A total of 960 radiomics features were initially computed and extracted from each 3D segmented tumour depicting on T2-weighted MR images. A univariate feature selection method was used to select high-performance features. We used an SVM machine-learning classifier to build two models by using selected clinical and radiomics features, respectively. Receiver operating characteristics curve (ROC) analysis was used to assess the performance of each model and compared with two radiologists.
Results: 3 clinical and 5 radiomics features were selected for prediction models. The clinical-radiomics fusion model can significantly improve the performance (AUC: 0.87±0.03, p<0.001) compared with a T2 MR image-based model (0.78±0.04) and clinical information based model (0.74±0.05), respectively. Two radiologists achieved no significant difference in AUC values (0.85 vs 0.82, p=0.37). In comparison, the fusion model yields significantly higher performance compared with two radiologists (p<0.001).
Conclusion: The clinical-radiomics fusion model can improve the performance in characterising T2-hyperintense uterine mesenchymal and mixed tumours, and can outperform experienced radiologists.
Limitations: The sample size was relatively small. We only included patients with T2-hyperintense uterine mesenchymal and mixed tumours, introducing a selection bias. Only T2WI were used for radiomics feature analysis in our study , to minimise variability in acquisition parameters. Other useful sequences such as DWI or dynamic contrast-enhanced images were not used.

Diffusion kurtosis imaging of endometrial carcinoma
S. Satta, M. Dolciami, F. Di Stadio, S. Capuani, L. Manganaro, C. Catalano; *Rome/IT (seresatta@gmail.com)*

Purpose: To assess the usefulness of diffusion kurtosis imaging (DKI) as a noninvasive method for detecting and evaluating endometrial cancer (EMC).
Methods and materials: 18 consecutive patients with a histological diagnosis of EMC by biopsy and 19 healthy volunteers were enrolled. They underwent an MR exam with diffusion-weighted imaging (DWI), acquired using multiple b values (from b 0 to b 2500 s/mm2) for each subject. DKI parameters were calculated for each voxel, to obtain K (kurtosis) and D (diffusivity). We also evaluated conventional ADC. All DWI images were processed using an in-house program developed with MatLab software (R2016a; MathWorks, Natick, MA). For K and D maps, regions of interest (ROIs) were manually drawn approximately equivalent in size to tumoural tissue and myometrium for EMC and to endometrium and myometrium for healthy patients, using DWI and T2W as references. Mean ± SD of K, D, and ADC values for uterine wall layers and EMCs were calculated and differences analysed using an Anova test.
Results: ADC (*10-3 mm2/s): EMC 0.87±0.22; healthy 0.96±0.23; p - D (*10-3 mm2/s): EMC 1.05±0.30; healthy 1.14±0.25; p - K (u.a.): EMC 1.12±0.30; healthy 0.63±0.18; p 0.015. K significantly discriminated between a tumour and healthy tissue (p=0.015), whereas D and ADC didn't discriminate.
Conclusion: Kurtosis imaging seems to be more sensitive compared to conventional diffusion imaging in detecting EMC. These results are promising and the difference between EMC and healthy layers may be used to precisely predict myometrial infiltration during MR examination.
Limitations: A limited number of patients.
Ethics committee approval: The study was approved by an ethics committee. Every patient gave written informed consent.
Funding: No funding was received for this work.

Virtual metabolic biopsies using hyperpolarised carbon-13 MRI to unravel metabolic heterogeneity in renal tumours
S. Ursprung, R. A. Woitek, M. A. McLean, A. S. Costa, A. Warren, C. Frezza, E. Sala, G. Stewart, F. A. Gallagher*; Cambridge/UK (su263@cam.ac.uk)*

Purpose: Renal cell cancer is the most common renal neoplasm and has recently been recognised for its genetic and metabolic intratumoural heterogeneity, contributing to tumour evolution, aggressiveness and treatment failure. Hyperpolarised [1-^{13}C]pyruvate (hp^{13}C-pyruvate) magnetic resonance imaging (hpMRI) allows the non-invasive assessment of pyruvate metabolism, but it is not known how this correlates with tissue-based molecular assays.
Methods and materials: Tumour metabolism was imaged in three patients with renal tumours using hpMRI. Following injection of hp^{13}C-pyruvate, metabolic images were acquired from 3 cm thick axial slices using an 8-channel-array coil on a 3T MRI with a temporal and spatial resolution of 4 s and 1.7 x 1.7 cm in-plane. Lactate concentrations measured using liquid chromatography-mass spectrometry (LC-MS) on perfused and ischaemic tissue samples were correlated with hpMRI-based metabolite signals.
Results: The tumours demonstrated a higher exchange rate for the hp^{13}C-label between pyruvate and lactate (k_{PL}: 0.010 ± 0.004s^{-1}, mean ± S.D.) than the normal kidney (0.003 ± 0.001s^{-1}). The parametric maps demonstrated intratumoural metabolic heterogeneity with at least two metabolically distinct tumour regions in each patient and higher metabolic heterogeneity in higher-grade tumours. Metabolic differences observed on imaging were replicated in tissue samples obtained before and after vascular exclusion, despite showing signs of ischaemia. A strong positive correlation (rho = 0.73, p = 0.003) was observed between lactate SNR on imaging and tissue concentrations measured with LC-MS (Figure 2).
Conclusion: Hyperpolarised ^{13}C-pyruvate demonstrates metabolic intratumoural heterogeneity in renal cancer and imaging-based lactate levels correlate with steady-state tissue lactate concentrations. Hyperpolarised imaging may guide biopsies to regions of metabolically aggressive regions of the tumour.
Limitations: Limited patient number with ongoing recruitment.

Assessing tumour cell death in vivo using deuterium magnetic resonance spectroscopic imaging
F. Hesse, V. Somai, F. Kreis, F. Bulat, K. Brindle*; Cambridge/UK (friederike.hesse@cruk.cam.ac.uk)*

Purpose: To demonstrate that fast deuterium MRI can be used for detecting cell death and to assess early tumour treatment response.
Methods and materials: Methods for detecting early evidence of cell death were investigated in three different tumour models (blood, breast and colorectal cancer) by applying a fast 3D deuterium MRI pulse sequence with a time resolution of 5 minutes, following a bolus injection of [2,3-$^{2}H_2$] fumarate, before and 48 h or 24 h after treatment with a chemotherapeutic or a novel targeted agent, respectively. In vitro experiments were conducted on a 14.1 T high-resolution NMR spectrometer, whereas in vivo results, were gained on a 7.0 T horizontal bore magnet.
Results: Deuterium metabolic imaging (DMI) experiments in vivo were conducted in the same tumour models on three mice each to generate metabolic maps with high spatiotemporal resolution. A fast chemical shift imaging sequence allowed to assess tumour conversion of [2,3-$^{2}H_2$]fumarate to [2,3-$^{2}H_2$]malate following a bolus injection of labelled fumarate. Within 48 h of drug treatment, the malate/fumarate ratio increased significantly from 0.034 ±0.06 to 0.33 ±0.11 (p=0.04).
Conclusion: Deuterium MR spectroscopic images can provide quantitative and spatially resolved measurements of cell death imaging. This study demonstrates the potential of DMI for assessing early tumour responses to treatment in the clinic.
Limitations: Deuterium tracer possesses a relatively low sensitivity, which may constrain imaging spatiotemporal resolution. Injecting higher concentrated substrates remedied this limitation.
Ethics committee approval: Animal experiments were carried out in compliance with a project and personal license issued by the Home Office, approved by the Cancer Research UK, Cambridge Institute Animal Welfare and Ethical Review Body.
Funding: No funding was received for this work.

Improving longitudinal transversal relaxation of gadolinium chelate using silica coating magnetite nanoparticles
K. Xu, W. Zhang*; Chongqing/CN (292494513@qq.com)*

Purpose: Precisely and sensitively diagnosing diseases - especially early and accurate tumour diagnosis in clinical magnetic resonance scanner - is a highly demanding but challenging task. Gadolinium (Gd) chelate is the most common T_1 MRI contrast agent at present. However, traditional Gd-chelates are suffering from low relaxivity, which hampers its application on clinical diagnosis. Currently, the development of nano-sized Gd based T_1 contrast agent, such as incorporating gadolinium chelate into nanocarriers, is an attractive and feasible strategy to enhance the T_1 contrast capacity of Gd chelate. The objective of this study was to improve the T_1 contrast ability of Gd-chelate by synthesizing nanoparticles (NPs) for accurate and early diagnosis in clinical diseases.
Methods and materials: A reverse microemulsion method was used to coat iron oxide (IO) with a tunable silica shell and to form cores of NPs IO@SiO2 at step one. Then, Gd-chelate was loaded on the surface of the silica-coated iron oxide NPs. Finally, the Gd-based silica coating magnetite NPs IO@SiO2-DTPA-Gd was developed, and we tested the ability to detect tumour cells on a cellular level.
Results: The r_1 value of IO@SiO_2-DTPA-Gd with the silica shell thickness of ~ 11 nm is about 33.6 mM^{-1}s^{-1}, which is approximately six times higher than Gd-DTPA. Based on its high T_1 contrast ability, IO@SiO_2-DTPA-Gd can effectively detect tumour cells on a cellular level.
Conclusion: Our findings revealed an improvement of T_1 relaxation that was not only caused by the increase of molecular tumbling time caused by the IO@SiO_2 nanocarrier but also by the generated magnetic field caused by the iron oxide NPs. This nanostructure with high T_1 contrast ability may open a new approach to constructing a high-performance T_1 contrast agent.
Limitations: The study is limited by a lack of MRI detecting in vivo.

Extradomain-B fibronectin-targeting nanoprobe for FL/PA/CT trimodal accurate imaging and risk-stratification of breast cancer

D. Yao, Y. Wang, D. Wang; *Shanghai/CN (yaodefan@126.com)*

Purpose: Extradomain-B fibronectin (EDB-FN) is a marker for epithelial-to-mesenchymal transition (EMT), a biological process associated with tumour invasion, metastasis and drug resistance. EDB-FN is highly expressed in the extracellular matrix of aggressive human breast cancers. For non-invasive accurate detection and risk-stratification of breast cancer, a peptide-targeted gold nanorod, Pep-Sq@AuNRs, is synthesised for sensitive fluorescent, photoacoustic and computed tomography (FL/PA/CT) imaging of extradomain-B fibronectin in aggressive breast tumours.
Methods and materials: An EDB-FN-targeted peptide modified gold nanorod, Pep-Sq@AuNRs, was synthesized using a three-step process, and this probe is composed of three moieties. The first moiety is an EDB-FN-targeted peptide (Pep), preferably targeting EDB-FN. The second moiety is a NIR fluorescent dye (Sq), of which its essential properties of NIR FL/PA imaging and phototherapy. The third moiety is gold nanorods (AuNRs), acting as CT/PA contrast agent.
Results: This complex probe can effectively target aggressive MDA-MB-231 triple-negative breast cancer in mice, but not in low-risk slow-growing MCF-7 tumours. The NIR FL/PA signals were activated by EDB-FN for imaging, and the AuNRs were used for CT imaging and photothermal/photodynamic therapy (PTT/PDT). These results demonstrate that trimodal imaging with Pep-Sq@AuNRs may provide accurate detection and risk-stratification of breast cancer.
Conclusion: In summary, we developed a novel platform, Pep-Sq@AuNRs, as a model to distinguish aggressive MDA-MB-231 triple-negative breast cancer and low-risk slow-growing MCF-7 tumours in mice. The results demonstrate that Pep-Sq@AuNRs could effectively target the aggressive MDA-MB-231 triple-negative breast cancer and kill cancer cells by PTT/PDT.
Limitations: There are no limitations to this study.
Ethics committee approval: The animal handling was approved by the Ethics Committee of Xinhua Hospital, affiliated to Shanghai Jiao Tong University School of Medicine.

Novel complementary molecular imaging tools to monitor immunometabolic crosstalk in a rabbit model of liver cancer

L. J. Savic[1], L. Doemel[2], I. Schobert[1], M. Lin[2], R. J. Bucala[2], N. Goldberg[3], F. Hyder[2], D. Coman[2], J. Chapiro[2]; *[1]Berlin/DE, [2]New Haven, CT/US, [3]Jerusalem/IL (lynn-jeanette.savic@charite.de)*

Purpose: To establish novel complementary molecular imaging tools for non-invasive monitoring of metabolic (extracellular pH, pHe) and immune activities of the liver tumour microenvironment.
Methods and materials: Fifteen VX2 liver tumour-bearing rabbits were used: A) Nine rabbits underwent pHe-mapping after conventional transarterial chemoembolisation (cTACE, n=3), cTACE with pHe-buffering bicarbonate (n=3), or as untreated controls (n=3). B) Three rabbits received ^{160}Gadolinium-labeled anti-HLA-DR antibodies intra-arterially to detect antigen-presenting cells. C) Three animals received rhodamine-conjugated small iron oxide nanoparticles (SPION) intravenously to detect macrophage distribution. MRI was performed on clinical 3T-scanners before and 24hrs after treatment, including pHe, T1- and T2-weighted imaging. Immunohistochemistry (IHC) staining of HLA-DR and CD11b, Prussian blue staining, fluorescence microscopy of rhodamine, and imaging mass cytometry (IMC) of gadolinium were compared to MRI signal distribution.
Results: pHe-mapping of untreated tumours revealed tumour acidosis (pHe=6.75±0.02) compared to liver parenchyma (7.19±0.02, p<0.001). Bicarbonate-cTACE significantly increased tumour-pHe (6.98±0.03) compared to controls (p=0.024) and cTACE alone (pHe=6.86±0.05, p=0.008). Moreover, acid neutralisation was accompanied by restored immune cell infiltration in the peritumoral rim, which was not detectable after cTACE alone. T1-weighted MRI with^{160}Gadolinium-labelled antibodies revealed localised peritumoural ring enhancement, which corresponded to gadolinium distribution patterns detected by IMC. T2-weighted MRI with SPION showed curvilinear signal hypointensity due to selective peritumoral SPION deposition in macrophages.
Conclusion: ^{160}Gadolinium- and SPION-based molecular imaging allows for specific labelling of peritumoural immune cells that are eliminated by cTACE and restored with acid neutralisation as detected by pHe-sensitive MRS. Thus, these monitoring tools may improve the assessment of susceptibility and response to immuno-oncological and loco-regional therapies.
Limitations: Limited spatial resolution and limited number of subjects (pilot project).
Ethics committee approval: Animal protocols were approved by the Animal Care and Use Committee.
Funding: Funding by the National Institutes of Health (R01 CA206180, EB-023366) and the Society of Interventional Oncology.

Target-specific in vivo imaging of tumour-immune interaction: evaluation of the regulatory protein S100A9

A. Helfen, J. Rieß, A. Schnepel, O. Fehler, M. Gerwing, M. Masthoff, W. Heindel, M. Wildgruber, M. Eisenblaetter; *Muenster/DE, (anne.helfen@ukmuenster.de)*

Purpose: Tumour progression and metastasis depend on tumour-infiltrating immune cells, which form a characteristic inflammatory tumour microenvironment (TME). As a promoter of tumour invasion and TME formation, the protein heterodimer S100A8/A9 released by activated infiltrating monocytes is associated with poor prognosis. Our aim was to develop an in vivo imaging tool as a biomarker for TME influence on tumour behaviour.
Methods and materials: From syngeneic murine breast cancer tumours 4T1 (highly malignant) and 67NR (low malignancy), wildtype (wt) and S100A9 knock out cells (CRISPR/cas9-method, ko) were created and implanted into either female BALB/c wildtype or S100A9$^{-/-}$-mice (n=10 each). At 4mm tumour diameter, anti-S100A9-Cy5.5-driven fluorescence reflectance imaging has been performed 0 and 24h after injection (contrast-to-noise ratios of fluorescence intensities in arbitrary units, AU). In vivo imaging was correlated with immunohistology, Western Blot and FACS analyses.
Results: In S100A9$^{-/-}$-mice fluorescence signals were significantly reduced for wildtype (4T1: 62,9 vs. 43,02AU;p=0,048, 67NR:52,73 vs. 27,26;p=0,033) and S100A9$^{-/-}$-tumours (4T1ko:65,33 vs. 42,51AU;p=0,005; 67NRko:54,61 vs. 34,19AU; p=0,006). However, no significant differences were detected for 4T1ko and 67NRko cells as compared with wildtype cells (4T1:p=0.543, 67NR:p=0.85). In all subgroups, the fluorescence signal was significantly higher in 4T1 as compared to 67NR tumours, reflecting their higher malignant potential. Imaging results were confirmed by ex-vivo analyses. Furthermore, FACS indicated an immune cell shift to immature monocytes within the S100A9-positive TME.
Conclusion: Our results in the 4T1/67NR breast cancer model confirm a secretion of S100A8/A9 by components of the TME, while tumour cells do apparently not release S100A8/A9. S100A9-specific in vivo imaging reflects tumour malignancy and may serve as a biomarker for TME formation and activity.

Cathepsin B-activated nanoparticles for multimodal imaging-guided photodynamic therapy to breast cancer

Y. Wang, D. Yao, D. Wang; *Shanghai/CN (wangyanshu_1992@sina.com)*

Purpose: Breast cancer is one of the most devastating malignancies in women. Photodynamic therapy (PDT) is widely investigated as alternative treatment for breast cancer due to its unique advantages. In light of upregulated cathepsin-B (CTSB) in breast cancer, we synthesized a targeted near-infrared activatable

probe (Pep-SQ@USPIO) for MRI/fluorescent/photoacoustic (MRI/NIR FL/PA) imaging-guided PDT.
Methods and materials: Pep-SQ@USPIO based on USPIO core modified with Pep-SQ. The sequence of Pep-SQ consisted of two moieties: the first moiety is fibronectin targeted peptide which labelled with a green fluorescent group, naphthalimide; the second moiety is a NIR fluorescent dye (SQ), of which it's essential properties of NIR FL/PA imaging and PDT. The two moieties linked via a cathepsin B-sensitive peptide (GFLG) linker. Transmission electron microscopy images, hydrodynamic size profiles, absorption spectra, cck-8 assay and oxidative stress elevation were acquired. The influence of "turn on" the fluorescence signal was studied in vitro and in vivo. The in vivo mice with tumour model was applied to evaluate imaging and photodynamic therapy efficacy.
Results: Pep-SQ@USPIO is almost nonfluorescent with inactivated phototoxicity and successfully applied to MR/PA imaging. After cancer cellular uptake, the cleavage of the GFLG substrate by CTSB led to recovering the quenched NIR FL signal, resulting in a high tumour/normal signal ratio. Upon treatment with 660 nm laser irradiation, generated reactive oxygen species (ROS) would produce PDT and enable remarkable tumour inhibition.
Conclusion: This tumour-specific theranostic probes can precisely diagnose and exerts further selective treatment, which may address challenges faced by traditional medicine in breast cancer.

Functionalised nanoparticles for bone micro-fractures with spectral photon-counting CT

C. Lowe[1], F. Ostadhossein[2], M. Moghiseh[1], M. Anjomrouz[2], R. K. Panta[1], A. Y. Raja[1], A. P. H. Butler[1], D. Pan[3], M. Collaboration[1]; [1]*Christchurch/NZ,* [2]*Urbana/US,* [3]*St. Louis, MO/US (Mahdieh.moghiseh@otago.ac.nz)*

Purpose: We visualise bone microdamage with functionalised nanoparticles in excised human phalanx and whole rat specimens. Spectral photon-counting CT using a MARS scanner allowed characterisation of bone microdamage, microarchitecture, mineralisation, and composition. Such characterisation is essential to assess bone quality and the toughening mechanism of bone.
Methods and materials: Biological specimens involved imaging of the excised human phalanx followed by incubation in ligand targeted hafnia nanoparticles (HfO_2 NPs) and two rat specimens which were anaesthetised and received scalpel-induced bone microdamage in one hind limb. One rat received functionalised, and the other received non-functionalised, HfO_2 NPs via intramuscular injection. Five hours post-injection, the animals were euthanised and scanned with MARS scanner. MARS is a small-bore photon-counting scanner employing energy resolving detectors and an x-ray tube operated at clinical x-ray energies, 118kVp. Four energy bins (30-45, 45-65, 65-80, 80-118 keV) and energy resolution of 3.5 keV, were used for imaging, with a cubic reconstruction voxel size of 90 µm.
Results: The MARS scanner produced quantitative images of HfO_2 nanoparticles, bone, and soft tissue using energy-dependent differences in x-ray attenuation. For the excised phalanx, HfO_2 nanoparticles highlighted expected regions of bone microdamage at high specificity (> 70% identification success for ≥ 10 mg/mL). In the injured rat limb, measured delivery of ligand targeted HfO_2 nanoparticles was 6.4 mg.
Conclusion: We have shown that spectral photon-counting imaging enables specific identification and quantification of HfO_2 functionalised nanoparticles that were targeted at bone microfractures, an important capability for the assessment of bone quality.
Limitations: n/a

Quantification of various calcium crystals for gout, pseudo-gout and other arthropathies using spectral photon-counting CT

Y. Sayous[1], I. Bernabei[2], A. Viry[2], N. Busso[2], A. P. H. Butler[1], L. Stamp[1], F. Becce[2], A. Y. Raja[1], M. Collaboration[1]; [1]*Christchurch/NZ,* [2]*Lausanne/CH (yann.sayous@gmail.com)*

Purpose: To confirm a method for distinguishing various calcium crystals in a range of arthropathies, in preparation for planned imaging studies of excised specimens and patients. Distinguishing crystal-associated arthropathies non-invasively and early in the disease course remains a challenge with traditional imaging techniques. Our method provides 3D maps of 90 μm^3 voxels of crystal type that should allow earlier treatment options.
Methods and materials: A MARS spectral photon-counting scanner was used to scan calibration rods of three concentrations of each of monosodium urate (MSU), calcium pyrophosphate (CPP) and calcium hydroxyapatite (HA). The images were acquired using four energy channels (20-30, 30-40, 40-50 and 50-80 keV) with a 3.5 keV resolution. The crystal types were distinguished by comparing energy-dependent attenuation coefficients. First, to assess the performance of the system, receiver operating characteristic curves were used. Then the system was tested on the different rods to evaluate identification efficiency.
Results: System performance demonstrates, using pairwise areas under the curves (AUC), that all concentrations of MSU were readily differentiated from the two higher concentrations of CPP and HA with an AUC > 0.90. The highest concentrations of CPP and HA (200 mg/cm^3) were well differentiated from each other, while 100 mg/cm^3 of CPP and HA showed a fair differentiation. The tests from the rods demonstrate that spectral photon-counting CT can identify high concentrations of CPP and HA (correct identification up to 80%) and significant ability to identify MSU (correct identification up to 90%).
Conclusion: We are able to identify and quantify important calcium crystals across a range of clinically relevant concentrations. This enables us to study arthropathies in excised samples and patients using existing MARS research and human scanners.

Histology of atherosclerotic plaque compared with tissue components measured using a spectral photon-counting CT

S. Dahal[1], E. Searle[2], S. Gieseg[2], A. Y. Raja[2], A. P. H. Butler[2], M. Collaboration[2]; [1]*Kathmandu/NP,* [2]*Christchurch/NZ*

Purpose: To confirm a method for non-invasively measuring four tissue components in atherosclerotic plaques. We compare the histology of plaques to 3D quantitative images of fat, water, calcium, and iron generated by a spectral photon counting CT.
Methods and materials: Arterial plaques obtained from carotid endarterectomy and scanned with a MARS spectral photon-counting CT. Following MARS imaging, the plaques were decalcified and fixed, then stained for protein, lipid, and iron. Histological photos were then taken of the stained tissue slices. The MARS scanner was operated at 120kVp with four energy channels with 3.5 keV resolution. This provided 3D maps of 90 µmcubic voxels of the four tissue components. Reference materials for calibration were ferric nitrate,

hydroxyapatite, oil, and water. The four maps of tissue components were compared to corresponding regions within the histological images.
Results: We will present tissue component maps alongside histological images. The images show: 1) regions of lipid deposits; 2) micro and macro calcification; 3) iron deposition; 4) thickness of the fibrous cap; 5) and ulcerations.
Conclusion: We have confirmed that the four maps of tissue components agree with histological analysis. Our technique non-invasively measures key features of some unstable plaque. The measurements are quantitative and in 3D. This enables us to study plaque in excised samples and patients using existing MARS research and human scanners.

CT radiogenomic characterisation of non-small cell lung carcinoma with EGFR and ALK mutation
G. Sharma, R. Sudhir, V. Koppula*; Hyderabad/IN*
(ggaurav.sharma@yahoo.co.in)

Purpose: Radiogenomics, focussing on defining relationships between "image phenotypes" and "molecular phenotypes", is currently considered a promising new paradigm for extending clinical imaging into the era of molecular imaging. The purpose of this study is to assess the association between CT imaging features of non-small cell lung carcinoma with EGFR and ALK mutation and HPE and demographic correlation in NSCLC with EGFR & ALK mutation.
Methods and materials: A prospective observational study, conducted at our institute, for a period of 18 months. Patients with pre-treatment CT chest of the primary tumour at our institution with the histological diagnosis of non-small cell lung carcinoma and data on EGFR and/or ALK rearrangement status were included in this study.
Results: A total of 156 patients, 87/156 (55.8%) males and 69/156 (44.2%) females were included in the study. This study demonstrated that the female gender (p=0.0065), spiculated margin (p=0.0195), GGO (p=<0.0001), pleural retraction (p=0.0023), absence of emphysema (p=0.0003), nodule in primary tumour lobe (p=0.0321), pleural effusion on same side of the tumour (p=0.0003) and metastatic lymphangitis carcinomatosis (MLC) (p=0.0004) were significantly associated with EGFR positivity, while bigger a size of a lesion (p=0.0259), central distribution (p=0.0215) of the primary lesion, pleural retraction (p=0.022), nodules in non-tumour lobe (p=0.003) and MLC (p=0.0159) were significantly associated with ALK mutation status.
Conclusion: This study affirms previous studies for a few CT characteristics and also found new correlations between CT imaging characteristics and the molecular status of NSCLC, providing supporting evidence for molecular targets that can be treated using molecular drugs.
Limitations: Limitations were the relatively smaller sample size for ALK mutation and that the pattern of contrast enhancement was not studied.

Mothership and drip-and-ship: does the initial treatment strategy in acute ischaemic stroke impact the outcome?
D. A. Weiss, C. Rubbert, M. Kaschner, P. D. M. S. Jander, M. Gliem, J.-I. Lee, C.-A. Haensch, B. Turowski, J. Caspers*; Düsseldorf/DE*
(DanielArvid.Weiss@med.uni-duesseldorf.de)

Purpose: Two strategies of initial patient care exist in endovascular thrombectomy (ET) depending on the site of initial admission: the mothership (MS) and drip-and-ship (DnS) principles. This study compares both strategies to clarify if one of them is superior in terms of patient outcome.
Methods and materials: 202 patients undergoing ET for anterior circulation ischaemic stroke were enrolled. Group comparisons in three-months modified Rankin scales (mRS) between both admission strategies were performed with the Mann-Whitney-U test and Spearman-correlation between admission strategy and mRS were analysed. A binary logistic regression (BLR) model was performed including mRS as the dependent variable and admission strategy, NIHSS, age, and onset-to-recanalisation-time as independent variables. Corresponding statistical tests were additionally performed in subgroups of patients with ET only or ET and intravenous thrombolysis (IVT).
Results: There were no significant group differences in three-month mRS between MS and DnS. However, a significant correlation between three-month mRS and admission strategy with lower mRS in MS principle was found in the subgroup of patients undergoing ET only. In patients treated with IVT and ET, this correlation was not significant. BLR showed a high explanation of variance in all models but no significant results for admission strategy.
Conclusion: The MS principle is superior to DnS in patients treated with ET only, probably due to time delay in the latter. However, in patients undergoing both IVT and ET, both strategies do not differ significantly. This indicates that bridging IVT is useful to reduce the unfavourable effect of transportation delay when local infrastructure necessitates DnS.
Limitations: The number of patients. No randomisation by intention.

RPS 1411b-2 11:31
CT-perfusion before and immediately after mechanical thrombectomy improves outcome prediction beyond clinical, angiographic, and standard imaging characteristics in patients with acute ischaemic stroke
G. Brugnara, M. Foltyn, U. Neuberger, S. Nagel, P. Ringleb, M. Bendszus, M. Möhlenbruch, J. Pfaff, P. Kickingereder*; Heidelberg/DE*
(gianluca.brugnara@med.uni-heidelberg.de)

Purpose: To investigate the value of CT-perfusion obtained before and immediately after mechanical thrombectomy (MT) for the outcome prediction in patients with acute ischaemic stroke.
Methods and materials: CT-perfusion was performed both before and immediately after MT in 42 patients. Perfusion maps (CBV, CBF, MTT, TMax, and TTP) were calculated and areas of hypoperfusion were segmented in the

baseline exam. Quantitative data was extracted from the segmented area at baseline and the corresponding area after MT. Full clinical and interventional data was available. Patient outcome was defined with the modified Rankin scale (mRS) at 90 days into mRS≤2 (good outcome) and mRS>2 (bad outcome). Multivariable logistic regression was performed to assess the value of baseline clinical data, ASPECTS, TICI score, and pre- and post-treatment CT-perfusion parameters for predicting the treatment outcome.
Results: Inclusion of both pre- and post-treatment CT-perfusion (in addition to clinical parameters, ASPECTS, and TICI score) yielded the best performance with an AUC of 0.903 (95% CI, 0.802-1.000). Specifically, pre- and post-treatment TTP (OR=0.401/1.51, p=0.012/0.029) as well as age (OR=1.113, p=0.041) were independent predictors of treatment failure. The performance of this model was significantly higher (p=0.013) compared to a model that included only pre-treatment characteristics (baseline CT-perfusion, clinical parameters, and ASPECTS) with an AUC of 0.830 (95% CI, 0.699-0.961). Models without CT-perfusion parameters performed significantly worse with an AUC of 0.780 (95% CI, 0.642-0.918) when based on clinical/angiographic parameters and ASPECTS only (p=0.023).
Conclusion: CT-perfusion parameters obtained immediately after MT improve the treatment outcome prediction in patients with acute ischaemic stroke beyond baseline clinical/angiographic parameters, ASPECTS, and pre-treatment CT-perfusion parameters.
Limitations: The small patient sample and lack of multicentric data.
Ethics committee approval: Approval obtained prior to analysis.
Funding: No funding was received for this work.

RPS 1411b-3 11:37

Correlation of histopathologic thrombi composition with CT/CT angiography, stroke aetiology, and thrombolysis administration in patients with endovascular treatment of acute ischaemic stroke

A. Klepanec[1], J. Haring[1], J. Harsany[1], M. Mako[1], M. Hoferica[1], M. Durovka[1], I. Mrvová[1], P. Janega[2], G. Krastev[1]; [1]Trnava/SK, [2]Bratislava/SK
(andrej.klepanec@gmail.com)

Purpose: To evaluate the correlation between histopathologic thrombus composition, stroke aetiology, radiological findings on non-enhanced CT (NECT), and CT angiography (CTA) and thrombolysis administration in patients undergoing endovascular treatment of acute ischaemic stroke.
Methods and materials: From August 2017-July 2018, we prospectively collected thrombi extracted from 138 consecutive patients during endovascular treatment of acute ischaemic stroke. Histopathologic composition of red blood cells, thrombocytes with fibrin, and leukocytes in thrombi were evaluated with morphometric analysis. Correlation between histopathologic thrombus composition, stroke aetiology, radiological findings on NECT, and CTA and thrombolysis administration was performed. Statistical analysis was performed with GraphPad Prism version 8.2 software (GraphPad Software, La Jolla, California).
Results: There was a significant increase in thrombus density on NECT with the increase of erythrocytes composition (p=0.007) and a decrease of thrombocytes with fibrin composition in thrombus (p=0.008). There was a significant correlation between dense artery sign on NECT and stroke aetiology (p=0.002) with a significant increase of dense artery sign on NECT in patients with atrial fibrillation (p<0.0001). No correlation between thrombus composition and stroke aetiology was found. Thrombus density on NECT and CTAG was significantly associated with stroke aetiology (p=0.0002 and p=0.046). Bridging intravenous thrombolysis did not influence the composition of erythrocytes and thrombocytes with fibrin in extracted thrombi (p>005).
Conclusion: Increased thrombus density on NECT correlates with increased erythrocytes and decreased thrombocytes with fibrin composition. Patients with atrial fibrillation have a significant increase in dense artery sign on NECT. Systemic thrombolysis does not influence the histopathologic thrombus composition.
Limitations: A single-centre study.
Ethics committee approval: The study was approved by the local ethics committee.

RPS 1411b-4 11:43

Cost-effectiveness of thrombectomy for ischaemic stroke patients presenting beyond 6 hours of the last known-to-be-well based on the AURORA meta-analysis

W. G. Kunz, D. Puhr-Westerheide, M. Unterrainer, M. P. Fabritius, P. Reidler; *Munich/DE (wolfgang.kunz@med.lmu.de)*

Purpose: The AURORA meta-analysis (analysis of pooled data from randomised studies of thrombectomy more than 6 hours after last known-well) included patients that were randomised to endovascular thrombectomy (EVT) or to medical management (MM) presenting with large vessel occlusion stroke beyond 6 hours of symptom onset or last known-to-be-well. Based on 5 pooled trials, EVT showed clear clinical benefits. We aimed to determine the cost-effectiveness of EVT in this context.
Methods and materials: A decision model estimated lifetime costs and quality-adjusted life-years (QALY) associated with EVT or MM. The analysis was performed in a US setting from a societal perspective. Input parameters were based on the most recent and best available evidence, including pooled outcome data from 5 randomised trials. Probabilistic sensitivity analyses (PSA) were performed using 10,000 Monte Carlo simulations to estimate uncertainty. Incremental costs (IC), effectiveness (IE), and cost-effectiveness ratios (ICER) were derived.
Results: Based on outcome data of 458 patients randomised within the AURORA meta-analysis, the base-case analysis identified EVT as the strategy that resulted in incremental QALYs and cost-savings over the projected lifetime compared to MM (IC: -$17,902; IE: +1.71 QALYs; ICER: EVT dominant). Adjusting for all input parameter uncertainty in PSA, EVT was the preferred strategy with acceptability rates of >99.9% at all willingness-to-pay thresholds ranging from $10,000 to $150,000 per QALY. Simulations led to 94.46% dominant/cost-saving iterations.
Conclusion: EVT is projected to provide considerable long-term clinical benefit whilst also leading to considerable long-term cost-savings in the management of patients with large vessel occlusion stroke presenting beyond 6 hours of symptom onset or last known-to-be-well.
Limitations: The cost calculations were conducted in the United States and the absolute amount cannot be converted to other countries. Yet, the overall findings of considerable cost-savings associated with EVT in extended time windows can be assumed for other care settings.

Reasons for failed recanalisation in mechanical thrombectomy of the posterior circulation

C. Weyland, U. Neuberger, M. A. Möhlenbruch; *Heidelberg/DE (charlotte.weyland@med.uni-heidelberg.de)*

Purpose: Why does mechanical thrombectomy (MT) of the posterior circulation sometimes fail? Failed MT in the posterior circulation has not been investigated and leads to a fatal outcome in most cases, while reasons for failed MT in the anterior circulation have been recently well defined.
Methods and materials: In this retrospective analysis of an institutional review board-approved prospective stroke database in a comprehensive stroke centre, we compared patients with successful and failed MT of the posterior circulation from March 2009-April 2019 (group A: mTICI 0-1 vs group B: mTICI 2-3). Cases of failed recanalisation were further investigated for reasons of MT failure. Statistical analysis included univariate and multivariate analysis for investigating clinical or interventional predictors of MT failure.
Results: 225 patients were analysed (group A: 30 and group B: 195). Group A showed a significantly lower follow-up pASPECTS after MT, a higher NIHSS at discharge, and a higher mRS 90 days after the stroke onset. The main reasons for a failed recanalisation were futile vascular access, a failed passage of the occluded vessel, and complications after passing the occlusion. Stent-assisted PTA was an independent predictor for MT failure and played a decisive role in most of the failed MTs atherosclerosis.
Conclusion: For the first time, this study depicts futile vascular access, failed passage of the vessel occlusion, and interventional complications to be main reasons for recanalisation failure in MT of the posterior circulation.

Atherosclerosis and the struggle with stent-assisted PTA in the posterior circulation are, opposed to failed MT in the anterior circulation, the main sources of revascularisation failure.
Limitations: The mono-centre retrospective approach.

Quantitative analysis of iodine in multiphase CT angiography: a potential tool for diagnosing stroke
V. Fransson[1], H. Mellander[2], J. Wasselius[2], K. Ydström[3]; [1]Lund/SE, [2]Malmö/SE, [3]Höör/SE (veronica.fransson@skane.se)

Purpose: Can quantitative measurements in vascular territories of the brain in multiphase CT angiography (MP-CTA) provide the same information as CT-perfusion (CTP) and be used to identify ischaemic regions after cerebral stroke?
Methods and materials: Patients were included on the basis of having undergone MP-CTA and CTP on a local dual-energy CT on suspicion of cerebral stroke. Another criteria was for the spectral-based images to be available for retrospective analysis. 9 patients were found, 5 without detected perfusion deficits on CTP and 4 with. Iodine density and HU, corresponding to a conventional 120 kV image and to a virtual mono-energetic image using 40 keV-photons, were measured in vascular territories of the brain for all phases of the MP-CTA exam and in the non-contrast CT. Iodine density and HU were plotted as functions of the imaged phase. The plots were evaluated by comparing the left and right hemispheres. Delayed arrival of the contrast material was deemed indicative of ischaemia. These results were then compared to the results of the CTP in order to see if a correlation could be found.
Results: Patients without detected perfusion deficits displayed little or no difference between hemispheres. Patients with perfusion deficits showed signs of ischaemia in some or all regions as the CTP. Iodine density generated a larger separation between healthy and ischaemic tissue than HU.
Conclusion: Quantitative analysis of MP-CTA shows the potential for being able to provide the same information as the CTP. Measurements performed on iodine density, instead of HU, generated a larger separation between sick and healthy tissue making it a more sensitive method.
Limitations: The limited patient material and data acquisition based on vendor-specific software.
Ethics committee approval: This study was approved by the ethics committee.
Funding: No funding was received for this work.

RPS 1411b-7 12:01
Automated cerebral attenuation measurements on single-phase CT angiography in stroke: a replacement for CT-perfusion?
P. Reidler, D. Puhr-Westerheide, M. P. Fabritius, L. Rotkopf, S. Maurus, D. Apel, T. Liebig, W. G. Kunz; *Munich/DE*

Purpose: To address the performance of automated attenuation measurements on CT angiography source images (CTASI) to detect ischaemic areas, the infarction core, and predict the final infarction in acute ischaemic stroke.
Methods and materials: In a retrospective analysis, we used software-based automated segmentation and Hounsfield unit (HU) measurements for all regions of the Alberta stroke program early CT score (ASPECTS) on CTASI in patients with large-vessel-occlusion (LVO) stroke. To normalise the values, we calculated relative HU (rHU) as a ratio of the affected/unaffected hemisphere. For the classification of ischaemic areas, the regional ischaemic core, and final infarction by rHU-values, we used simultaneously acquired CTP-data and follow-up imaging as a ground truth. Receiver-operating-characteristics analysis was performed to calculate the area-under-the-curve (AUC).
Results: 79 patients were included. rHU-values presented a significant classification of ischaemic involvement in all 10 regions of the ASPECTS with AUC from 0.72-0.99 ($p<0.001$, except M4-cortex $p=0.002$). Classification of the ischaemic core resulted in lower AUC values (0.55-0.87), however, it still provided a significant classification for all regions except M3- and M5-cortex. The final infarction was predicted with AUC values from 0.65-0.85, significant in all regions except M3- and M5-cortex.
Conclusion: Automated attenuation measurements on CTASI present an excellent performance in detecting ischaemic regions in LVO stroke patients. Significant classification of the regional ischaemic core and the prediction of the final infarction was able for most ASPECTS regions. This technique has the potential for stroke imaging triage and to reduce the use of CTP.
Limitations: The small study sample, the use of only one CT vendor (Siemens), and the global variability of CTA protocols.
Ethics committee approval: The study was approved by the IRB according to the declaration of Helsinki.
Funding: No funding was received for this work.

RPS 1411b-8 12:07
Artificial intelligence in stroke: evaluating the automated scoring of collaterals in acute stroke on computed tomography scans
M. Politi[1], A. Podlasek[2], R. Namias[2], S. Gerry[2], O. Joly[2], G. Harston[2], P. Papanagiotou[3], I. Q. Q. Grunwald[4]; [1]Athens/GR, [2]Oxford/UK, [3]Bremen/DE, [4]Chelmsford/UK (mariapoliti@hotmail.com)

Purpose: Computed tomography angiography (CTA) collateral scoring can identify patients most likely to benefit from mechanical thrombectomy and more likely to have good outcomes.
Our purpose was to generate an e-CTA collateral score (CTA-CS) for patients eligible for thrombectomy.
Methods and materials: A machine learning approach categorised collateral flow in 98 patients who received mechanical thrombectomy and generated an e-CTA collateral score (CTA-CS) for each patient. 3 experienced neuroradiologists (NRs) estimated the CTA-CS, first without and then with knowledge of the e-CTA output, before finally agreeing on a consensus score.
Results: e-CTA improved the intraclass correlation coefficient (ICC) between neuroradiologists from 0.58 (0.46-0.67) to 0.77 (0.66-0.85, $p=0.003$). e-CTA, without NR input, agreed with the consensus score in 90% of scans with the remaining 10% within 1 point of the consensus (ICC 0.93, 0.90-0.95). Sensitivity and specificity for identifying favourable collateral flow (collateral score 2-3) were 0.99 (0.93-1.00) and 0.94 (0.70-1.00), respectively.
Conclusion: e-CTA provides a real-time and fully automated approach to collateral scoring with the potential to independently quantify collateral scores even without expert rater input.
Limitations: The CTA-CS was generated under experimental conditions by specialist NRs without the time pressures of real-world clinical scenarios. In many healthcare settings, ready access to specialist neuroradiology input is not available. As such, the benefit of an automated e-CTA score may be greater than demonstrated here. Although NRs in this study were blinded to clinical data, all patients had a confirmed stroke and large vessel occlusion, knowledge of which was available to the expert scorers.
Ethics committee approval: The Freiburg ethics commission granted approval for the study (0171140).

RPS 1411b-9 12:13
Clinical decision support for visual ASPECTS cut-off values in patient selection for guideline-compliant thrombectomy using automated quantification of attenuation changes
D. Puhr-Westerheide, P. Reidler, S. Tiedt, L. Rotkopf, M. P. Fabritius, P. D. L. Kellert, F. Dorn, F. A. Wollenweber, W. G. Kunz; *Munich/DE (daniel.puhr-westerheide@med.uni-muenchen.de)*

Purpose: Large vessel occlusion (LVO) stroke leads to variable attenuations in ASPECTS regions on non-contrast CT (NCCT). Current guidelines recommend thrombectomy for patients with visually-assessed ASPECTS≥6 in the early time window. Our aim was to test the diagnostic performance of an automated assessment of regional hypoattenuation to identify evidence-based ASPECTS cut-off values for thrombectomy.
Methods and materials: We included 200 patients with an LVO stroke of the anterior circulation undergoing NCCT on admission. To ensure unbiased attenuation measurements, patients with prior contrast administration, prior

infarction, or pre-existing cerebral lesions were excluded. The ASPECTS was visually determined by two expert readers in consensus. An automated software tool was used to calculate the relative Hounsfield unit (rHU) values for ASPECTS regions compared to the non-ischaemic hemisphere. A composite rHU-ASPECTS, a score incorporating rHU from all regions, was used for comparison with the visually-assessed ASPECTS in regression analysis and receiver-operating-characteristics analysis.
Results: The median age was 74 years, median ASPECTS was 8 (IQR: 7-10), and 176 patients (88%) had an ASPECTS ≥6. We found a strong association of composite rHU-ASPECTS with visual ASPECTS in univariate regression (b=-0.560, p<0.001). Visually-rated early ischaemic signs in ASPECT regions were correctly identified by rHU values for all regions except the M1, M3, and M4. The highest discriminative value was found in the lentiform nucleus (AUC=0.892, p<0.001), the internal capsule (AUC=0.813, p<0.001), the caudate nucleus (AUC=0.779, p<0.001), and the insular cortex (AUC=0.776, p<0.001). The composite rHU-ASPECTS showed a high discriminative value for the identification of patients with ASPECTS<6 (AUC=0.779, p<0.001).
Conclusion: Automated assessment of regional hypoattenuations identified expert-classified visual ASPECTS cut-off values and may serve as a method to standardise stroke patient selection for thrombectomy.
Limitations: The retrospective, single-centre design.

RPS 1411b-10 12:19
The effect of different thresholds for CT-perfusion volumetric analysis on estimated ischaemic core and penumbral volumes
S. O. Karhi[1], O. I. Tähtinen[2], J. Aherto[1], H. P. Matikka[1], H. Manninen[1], O. Nerg[1], M. Taina[1], P. Jäkälä[1], R. Vanninen[1]; [1]Kuopio/FI, [2]Tampere/FI *(simkar@student.uef.fi)*

Purpose: This retrospective single-centre study compared three threshold settings for automated analysis of the ischemic core (IC) and penumbral volumes using computed tomographic perfusion (CTP) and their accuracy for predicting final infarct volume (FIV) in patients with anterior circulation acute ischaemic stroke (AIS).
Methods and materials: 52 consecutive AIS patients undergoing mechanical thrombectomy (November 2015–March 2018) were included. Perfusion images were retrospectively analysed using a single CT neuro perfusion application (syngo.via 4.1, Siemens Healthcare GmbH). 3 threshold values (S1–S3) were derived from another commercial package (RAPID; iSchema View) (S1), up-to-date syngo.via default values (S2), and adapted values for syngo.via from a reference study (S3). The results were compared with FIV determined by follow-up non-contrast CT.
Results: The median IC volume (mL) was 24.6 (interquartile range: 13.7-58.1), with S1 and 30.1 (20.1-53.1) with S2/S3. After removing the contralateral hemisphere from the analysis, the median IC volume decreased by 1.33 (0-3.14), with S1 versus 9.13 (6.24-14.82) with S2/S3. The median penumbral volume (mL) was 74.52 (49.64-131.91), 77.86 (46.56-99.23), and 173.23 (125.86-200.64) for S1, S2, and S3, respectively. Limiting the analysis to the affected hemisphere, the penumbral volume decreased by 1.6 (0.13-9.02), 19.29 (12.59-26.52), and 58.33 mL (45.53-74.84) for S1, S2, and S3, respectively. The correlation between IC and FIV was highest in patients with successful recanalisation in <113 min (r=0.881 for S1; r=0.877 for S2/S3).
Conclusion: Optimising threshold settings significantly improves the accuracy of the estimated IC and penumbral volumes. International consensus guidelines based on larger multicentre studies should be established to support the standardisation of volumetric analysis in clinical decision-making.
Limitations: The small patient population and CTP brain coverage limited to 10 cm leading to potential underestimation of IC or penumbral volume.
Ethics committee approval: Approved by the Hospital Research Ethics Board.

RPS 1411b-11 12:25
Virtual monoenergetic dual-energy CT reconstructions at 80 keV are optimal for early stroke detection
D. Dodig[1], S. Kovacic[1], Z. Matana Kaštelan[1], N. Bartolovic[1], S. Jurkovic[1], D. Miletic[1], Z. Rumboldt[2]; [1]Rijeka/HR, [2]Charleston, SC/US *(doris_5na5@yahoo.com)*

Purpose: Virtual monoenergetic (VM) dual-energy CT (DECT) imaging enables grey-to-white matter contrast-to-noise ratio optimisation, potentially increasing the visibility of ischaemic brain oedema. The aim of our study was to compare the diagnostic accuracy of early stroke detection on VM to weighted average (WA) reconstructions.
Methods and materials: Consecutive patients with brain DECT scanned within 12 hours of stroke symptom onset were prospectively included in the study. Patients having had other significant brain pathology were excluded. Two neuroradiologists evaluated in consensus WA and VM reconstructions (from 40 to 190 keV at 10 keV increments) for early stroke signs on a 4-point Likert scale: 1=stroke definitely present, 2=stroke probably present, 3=probably no stroke, and 4=definitely no stroke. A follow-up CT and/or MRI served as the standard of reference. Statistical evaluation was performed by ROC analysis.
Results: 44 patients (73%) developed stroke and 16 (27%) had no signs of a stroke on follow-up imaging. Ischaemic brain oedema detection was significantly more accurate on VM reconstructions at 80 keV compared to WA images with AUC 0.784 (95% CI 0.710, 0.858) and 0.685 (95% CI 0.588, 0.781), respectively (p=0.0339).
Conclusion: VM reconstructions at 80 keV are superior to polychromatic images for early stroke detection and are recommended for standard clinical protocol.
Limitations: Follow-up imaging served as the standard of reference, however, elapsed time and received treatment could have significantly influenced changes in brain pathology, thus making the comparison with initial brain DECT uncertain. Concurrent DWI MRI imaging would have been the preferred gold standard.
Ethics committee approval: Institutional review board approved this study. Informed consent was waived.

An MRI-DWI visual scale for tumour response evaluation in lymphomas
S. Kharuzhyk, E. Zhavrid, A. Dziuban; *Minsk/BY (skharuzhyk@nld.by)*

Purpose: To develop an MRI-DWI visual scale for tumour response evaluation in lymphomas and to compare its effectiveness with the PET/CT Deauville scale.
Methods and materials: The study included 97 patients with lymphoma. Post-treatment whole-body MRI-DWI was interpreted using a 5-level scale: 1=all lymph nodes (LNs) ≤1 cm in short-axis size with no extra lymphatic lesions, 2=LNs >1 cm and extra lymphatic organ lesions with signal intensity (SI)>muscles on ADC maps with no bone marrow (BM) lesions, 3=LNs >1 cm and organ lesions with SI equal to muscles on ADC maps with no BM lesions, 4=LNs >1 cm and/or organ lesions with SI<muscles on ADC maps and/or BM lesions, and 5=increase of lesions size and/or appearance of new lesions. Post-treatment PET/CTs were interpreted using a 5-level Deauville scale. Treatment response was classified as complete (CR, scores 1-3) or non-complete (NCR,

scores 4-5). Progression-free survival (PFS) and overall survival (OS) were compared in patients with CR and NCR.
Results: The number of chemotherapy courses was 3-8. According to MRI-DWI, 85 patients achieved CR and 12 NCR, PET/CT 75 and 22, respectively. The tumour response category coincided in 83 (86%) patients. 2-year PFS in patients with MRI-DWI CR and NCR was 87% and 22% (p=0.0), 3-year OS 93% and 64% (p=0.003), respectively. 2-year PFS in patients with PET/CT CR and NCR was 89% and 46% (p=0,0), 3-year OS 92% and 75% (p=0.013), respectively.
Conclusion: A simple MRI-DWI visual scale for tumour response evaluation in lymphomas was proposed. A high concordance with the PET/CT Deauville scale was demonstrated. The proposed MRI-DWI scale may be used as a non-irradiative alternative to the Deauville scale.

The correlation between shear-wave velocity in newly diagnosed lymphomas and the degree of intra-tumoural fibrosis: a proof of principle
K. Ekert, H. Bösmüller, M. Horger*; Tübingen/DE*

Purpose: To evaluate the role of shear-wave elastography for the potential characterisation of lymphoma subtypes through a comparison to the amount of intra-tumoural collagen.
Methods and materials: This was a prospective study including 24 patients (age 56.26 years, range, 17.95-83.39; 7 females) with histologically proven lymphomas who underwent shear-wave elastography and Masson-Trichrome staining of tumour tissue. Ultrasound-guided biopsies and ARFIs were performed in the same involved node in one session. A mean of 7.3 (range, 5-8) measurements quantifying the mean shear-wave velocity (SWV) (m/s) elasticity of lymphoma tissue were measured. The patients belonged to 3 larger groups of Hodgkin's lymphoma (HL), follicular lymphoma (FL), and diffuse large B-cell lymphomas (DLBCL). The amount of collagen contained in the tumours was quantified by Masson-Trichrome staining.
Results: The mean and max SWV in our patient series were 3.35 (±0.23) m/s and 5.98 m/s. In the subgroup of HL, the mean and max SWV were 3.17 (±0.31) m/s and 4.53 m/s, in the subgroup of FL they were 2.84 m/s (±0.88) and 3.98 m/s, and in DLBCLs, 4.72 (±0.85) m/s and 5.98 m/s were measured, respectively. The corresponding mean percentage of collagen was 20.0% (±20.0) for HL, 22.0% (±10.2) for FL, and 14.6% (±12.7) for DLBCL. SWV-values correlated significantly with the amount of collagen in the tissue both in the entire patient series (p<0.001) as well as in differentiating DLBCL from HL (p=0.01) and FL (p=0.006).
Conclusion: Shear-wave velocity in lymphomas correlates with the amount of collagen, in particular, in DLBCL and could be used for tumour characterisation and differentiation.
Limitations: The small cohort size. However, it is continuously growing.
Ethics committee approval: The ethics committee approved this study.
Funding: No funding was received for this work.

The influence of the MRI protocol on staging smoldering multiple myeloma patients according to the new SLIM–CRAB criteria
M. Wennmann[1], L. Kintzelé[1], T. Hielscher[1], G. Langs[2], M. Piraud[3], H.-U. Kauczor[1], J. Hillengass[4], B. Menze[3], M.-A. Weber[5]; *[1]Heidelberg/DE, [2]Vienna/AT, [3]Munich/DE, [4]Buffalo/US, [5]Rostock/DE*

Purpose: To investigate the spatial distribution of focal lesions (FLs) in whole-body MRI (wb-MRI) in smoldering multiple myeloma (SMM) patients and consequently the influence of the field of view of MRI (spinal vs wb) for upstaging SMM patients to multiple myeloma requiring systemic therapy according to the new SLIM-CRAB criterion ">1FL in MRI".
Methods and materials: The cohort consisted of 63 patients with overall 220 wb-MRI during follow-up and at least semiannual clinical follow-up until progression or for at least 3 years. All included wb-MRIs were performed on one of two identical 1.5 Tesla MRI systems at our site. Details on the wb-MRI protocol have been published before.
Results: In 23/220 wb-MRI cases, >1FL was apparent in spinal imaging, resulting in an indication for therapy regardless of further findings when wb-imaging was completed. When no FL was apparent in spinal imaging, only 16/171 cases revealed >1FL in wb-imaging. In 26 cases where 1 FL was revealed in spinal MRI, 12 showed >1FL when imaging was extended to wb-MRI.
Conclusion: When wb-MRI is not diagnostic standard in staging SMM patients due to time, cost, or technical restrictions, and spinal MRI is performed instead, the protocol for the subgroup of patients with 1 FL in the spine should be extended to wb-MRI, as half of these patients reveal >1FL in wb-MRI with the consequence of indication for systemic therapy according to the new SLIM-CRAB-criteria.
Limitations: The retrospective study design and the limited case number.
Ethics committee approval: This study was approved by the institutional ethics committee with a waiver of informed consent.

Radiogenomics in multiple myeloma
N. de Vos, J. C. Dutoit, M. Behaeghe, T. van Den Berghe, P. Vlummens, K. L. A. Verstraete*; Ghent/BE (devos.nicolas90@gmail.com)*

Purpose: To study the association between magnetic resonance imaging (MRI) features and genetic abnormalities in patients newly diagnosed with smouldering multiple myeloma (SMM) or multiple myeloma (MM).
Methods and materials: This retrospective study included 26 patients with a new diagnosis of SMM or MM. Patients underwent whole-body MRI (conventional MRI, diffusion-weighted imaging (DWI), and/or dynamic contrast-enhanced MRI (DCE)) from January 2016-October 2019. Extensive genomic testing (array comparative genomic hybridisation (array CGH), copy number variation sequencing (CNV sequencing), and/or fluorescence in situ hybridisation (FISH)) was performed within 2 months of the whole-body MRI. Fisher's exact test was used to test for non-random associations between MR imaging features and genomic abnormalities.
Results: 26 patients were included (women/men 14/12, mean age±standard deviation 63±10 years, range 41-77). 15 patients were diagnosed with SMM (58%), while 11 patients were diagnosed with MM (42%). 13 patients (50%) had focal lesions. In patients with focal lesions, favourable genetics (hyperdiploidy) were more common than in patients without focal lesions (p<0.05). In patients without focal lesions, unfavourable genetics (hypodiploidy) were more common than in patients with focal lesions (p<0.05). No statistically significant differences in genetic abnormalities were found in patients with increased diffusion restriction or steep first-pass enhancement (p>0.05).
Conclusion: In patients with a new diagnosis of SMM or MM, unfavourable genetics (hypodiploidy) are more common in patients without focal lesions, while favourable genetics (hyperdiploidy) are more common in patients with focal lesions.
Limitations: A retrospective monocentric study with a limited number of patients.
Ethics committee approval: The study was approved by the institutional review board of the Ghent University Hospital.

Magnetic resonance imaging in multiple myeloma: a focus on hip and proximal femur bone lesions and the MY-RADS score
F. Rossi, A. Dominietto, L. Torri, P. Francaviglia, G. Succio, A. Conte, S. Gualco, A. Tagliafico*; Genoa/IT (federossi0590@gmail.com)*

Purpose: Multiple myeloma (MM) is a haematological malignancy characterised by the clonal proliferation of plasma cells that determines bone lesions with different patterns of involvement. Due to prolonged corticosteroid therapy, MM patients have an increased risk of pathological fractures and osteonecrosis of

the proximal femur. According to the Durie & Salmon PLUS criteria and new MY-RADS score, MRI is of prognostic relevance to evaluate the disease extent (medullary and extra-medullary lesions).
Methods and materials: We reviewed MRI data from January 2018-August 2019 of n=52 patients (29 men and 23 women; mean age 65±13years) with MM at the level of the hip (including the proximal femur). Hip lesions have been classified according to the MY-RADS score and lesion characteristics in a diffuse pattern, focal pattern, mixed pattern, osteonecrosis, and pathological fractures. Descriptive statistical analysis was performed to summarise the dataset.
Results: Among the 52 selected MM patients, a total of n=40 (40/52; 77%) reported at least one hip lesion, n=10 patients at least two hip lesions (10/52; 20%), and n=2 (2/52; 3%) subjects had no lesions. According to hip lesions classification, n=6 osteonecrosis of the femoral head, n=26 diffuse pattern, n=10 focal pattern, n=15 mixed pattern, and n=5 pathological fractures were observed. Intra and interobserver agreement of MY-RADS score were 0.78 and 0.65, respectively.
Conclusion: MRI detects bone lesions in the hip and proximal femur in 97% of patients. In n=11/52, 21% of patients, a surgical consult was necessary. MRI allows the differentiation of bone pattern involvement in MM, which is useful for risk stratification using the MY-RADS score.
Limitations: The retrospective nature of the study and relatively small number of patients.
Ethics committee approval: The retrospective study protocol was approved by our institutional review board.
Funding: No funding was received for this work.

An increased bone mineral density as an adverse prognostic factor in patients with systemic mastocytosis

J. Krammer, M. Jawhar, W.-K. Hofmann, S. O. Schönberg, A. Reiter, P. Riffel; *Mannheim/DE (philipp.riffel@umm.de)*

Purpose: Systemic mastocytosis (SM) is characterised by the expansion of clonal mast cells that infiltrate various organ systems. The extent of organ infiltration and subsequent organ damage distinguishes between indolent SM (ISM, nearly normal life expectancy) and advanced SM (AdvSM, poor prognosis). In ISM patients, the measurement of the bone mineral density (BMD) frequently reveals osteoporosis. In contrast, the association between increased BMD and osteosclerosis, respectively, and the various SM subtypes is unclear.
Methods and materials: BMD values in 61 patients (ISM, n=29, 48%; AdvSM, n=32, 52%) were correlated with clinical parameters and prognosis. Osteoporosis was defined as a BMD T-score of ≤-2.5 SD. Increased BMD and osteosclerosis were defined as a Z-score of >1 SD and >2 SD, respectively.
Results: Osteoporosis was detected in 11/29 (38%) patients with ISM and 2/32 (6%) patients with AdvSM (p=0.004). Osteosclerosis was only detected in AdvSM patients (16/32, 50%). AdvSM patients with an increased BMD had higher levels of bone marrow mast cell infiltration, serum tryptase, and alkaline phosphatase (p<0.05). Consequently, the prognosis of AdvSM patients with increased BMD was significantly inferior compared to those without increased BMD.
Conclusion: Osteoporosis is a common feature in ISM. Increased BMD is frequent in AdvSM but not in ISM patients, while osteosclerosis is restricted to AdvSM patients. Elevated BMD is associated with a more aggressive phenotype and inferior survival.
Limitations: Disease duration could not be determined reliably because some patients were not able to recall the start of their symptoms and the exact timing of their disease diagnosis.
Ethics committee approval: The requirement of informed patient consent was waived by the institutional review board as this is a retrospective study. The study was performed in compliance with HIPAA guidelines.
Funding: No funding was received for this work.

RPS 1416b-8 11:57

Prognostic value of whole-body low-dose CT (WBLDCT) in the staging and restaging of patients with multiple myeloma (MM): a long period follow-up

T. P. Giandola[1], D. Ippolito[1], M. Ragusi[1], M. Porta[2], C. Maino[1], C. R. G. L. Talei Franzesi[3], S. Sironi[4]; *[1]Monza/IT, [2]Senago/IT, [3]Milan/IT, [4]Bergamo/IT (t.giandola@hotmail.it)*

Purpose: To evaluate, with WBLDCT, the prognostic features of bone marrow involvement and behaviour in patients with MM during a long follow-up period considering the dimensional parameter of bone lesions and according to the different infiltration pattern of disease.
Methods and materials: 100 patients with a clinical diagnosis of MM that underwent unenhanced WBLDCT scans followed during a long period (3-7 years) were enrolled in this study. WBLDCT was performed on 256-slice scanner with a tube voltage of 120kV and a tube current-time product of 40mAs. The whole skeleton was divided into 5 anatomic districts (the skull, spine sternum and ribs, pelvis, and upper/lower limbs) and evaluated in terms of infiltration pattern (focal, diffused, and combined) and the distribution of the disease. Moreover, the osteolytic bone lesions were categorised according to the maximum axial diameter (MAD), having 10 mm as the cut-off value.
Results: 63% of patients presented with the focal pattern, 22% had the diffuse pattern, and 15% had the combined pattern.
During follow-up, when considering the cut-off value >10 mm in MAD, 86 (82%)/105 analysed lytic lesions remained dimensionally unchanged, 11% showed a dimensional increase, and 7% showed a dimensional decrease.
59 patients with a lytic/combined pattern presented with multifocal lytic lesions with a MAD <10 mm and among them, 88% of the patients presented a dimensional stability of the lytic lesions, 2% showed a dimensional decrease of their lesions, and only 10% had a minimal dimensional increase (average of 5 mm) of the lytic lesions.
In patients with the diffuse pattern (38%), neither a modifications of the pattern nor a development of focal lytic lesions occurred during the follow-up.
Conclusion: WBLDCT represents a reliable imaging-based tool for the proper management of MM patients, which is useful to define the behaviour of different bone involvement, showing that the diffuse form of small lytic lesions (<10 mm) deserve less frequent follow-up.

The role of computed tomography texture analysis using dual-energy-based bone marrow imaging for multiple myeloma characterisation: a comparison with histology and established serologic parameters

C. P. Reinert, E. Krieg, M. Esser, K. Nikolaou, M. Horger; *Tübingen/DE (christian.reinert@med.uni-tuebingen.de)*

Purpose: To identify textural features on dual-energy CT (DECT) bone marrow images in multiple myeloma which correlate with the degree of medullary involvement assessed by histology and myeloma-related serologic parameters.
Methods and materials: 56 patients (63.9±11.8y) who underwent unenhanced DECT were evaluated. All patients had a bone marrow biopsy and current serum levels of immunoglobulins and serum-free light chains (SFLC). Using DECT post-processing, bone marrow images were reconstructed. The vertebral bodies T10-L5 were segmented for quantification of 1st, 2nd, and higher-order textural features based on a pyradiomics library, which were compared between myeloma stages, serologic parameters, and the presence/absence of osteolyses. Absolute values of textural features were correlated with the degree of bone marrow infiltration.
Results: 1st order features were higher in patients with stage 2/3 compared to stage 1 (p<0.02), whereas the 2nd order feature "GLCM cluster prominence" was lower (p<0.04). The 1st order "entropy", 2nd order GLCM features, and the higher-order "GLRLM high grey-level run emphasis" were lower in patients with elevated SFLC or pathological kappa/lambda ratios (p<0.03). In contrast, "GLRLM run variance" was higher (p<0.03), which was also observed in patients with osteolyses (p<0.007). The degree of bone marrow infiltration was positively correlated with 1st order features (e.g. "uniformity"; r_P=0.49; p<0.0001), whereas "entropy" and GLCM features were negatively correlated (e.g. "difference entropy"; r_P=-0.54; p<0.0001).
Conclusion: CT-textural features applied on non-calcium bone marrow images correlate well with myeloma-related serologic parameters and histology, showing a more uniform tissue structure with increasing medullary infiltration and

could be used as an additional imaging biomarker for the non-invasive assessment of medullary involvement.
Limitations: A retrospective study.
Ethics committee approval: Approved by the review board.

RPS 1416b-10 12:09

Advantages of whole-body diffusion-weighted MRI (WBMRI) versus whole-body low-dose CT in young patients affected by multiple myeloma (MM): a retrospective analysis

F. Castagnoli[1], A. Villanacci[1], V. Angelini[2], A. Belotti[1], B. Frittoli[1], L. Grazioli[1];
[1]Brescia/IT, [2]Naples/IT (francy-cast@hotmail.it)

Purpose: To compare CT and WBMRI in staging and follow-up during and post-therapy in young MM patients.
Methods and materials: From September 1, 2018-July 31, 2019, 219 WBMRI were performed with a Magnetom Aera 1.5T (Siemens Healthcare, Erlangen, Germany) using established protocols.
We reviewed 121 exams (89 patients, median age: 58.3). All had a histological report by bone marrow biopsy and a low-dose CT was performed.
Results: In 28/89 patients, we found a diffuse infiltration pattern at WB-DWI defined as hyperintensity in STIR sequences, hypointensity T1, and signal restriction in DWI of the spongy vertebral body. In 26 cases, the diagnosis was confirmed by a histological bone marrow report, with 2 false-positives and high concordance between the two methods. The plasma cell infiltration rate did not correlate with the grade of signal restriction on DWI. Instead, the DWI/ADC values correlated with the response to therapy.
In 43/89 patients (48.3%), the WBMRI protocol showed extraskeletal findings (benign and malignant) that previous CT-staging did not report; some of them (3 breast cancer, 4 prostatic cancer, 1 renal cell carcinoma, 1 HCC, 1 colon cancer, and 1 jugular thrombosis) changed the clinical treatment.
Conclusion: WBMRI is a functional imaging technique comprising anatomical and functional sequences with an emerging role in the management of MM patients. It allows highly sensitive detection of diffuse bone marrow infiltration patterns and focal lesions according to the International Myeloma Working Group Consensus Reccomandation (June 2019).
In our study, we found that, when available, WBMRI should be the first choice in young patients with MM to avoid radiation exposure.
Limitations: A retrospective study.

RPS 1416b-11 12:15

The diagnostic efficacy of whole-body low-dose CT in the staging of patients with multiple myeloma compared to whole-body magnetic resonance imaging

T. P. Giandola[1], D. Ippolito[1], M. Ragusi[1], M. Porta[2], C. Maino[1],
C. R. G. L. Talei Franzesi[3], S. Sironi[4]; [1]Monza/IT, [2]Senago/IT, [3]Milan/IT,
[4]Bergamo/IT (t.giandola@hotmail.it)

Purpose: To compare the diagnostic efficacy of whole-body low-dose CT (WBLDCT) with whole-body magnetic resonance imaging (WBMRI) in the evaluation of bone marrow involvement and behaviour in different infiltration patterns in patients with multiple myeloma (MM).
Methods and materials: 44 patients with histologically-confirmed MM underwent WBLDCT and WBMRI. Unenhanced WBLDCT was performed on a 256-slice scanner with a tube voltage of 120 kV and tube current-time product of 40mAs. WBMRI was performed on a 1.5T with the acquisition of T1 TSE and T2 STIR sequences (coronal and sagittal plane), and axial DWIBS sequences, with different b-values (0.500 and 1,000 mm2/s). The whole skeleton was divided into 5 anatomic districts (the skull, spine, sternum and ribs, and upper and lower limbs) and evaluated in terms of infiltration patterns. WBLDCT findings were then compared with WBMRI findings.
Results: On WBMRI, 24%of patients presented with osteolysis (focal/combined pattern) with a total of 204 lytic lesions detected (3% in the skull, 10% in the upper limbs, 25% in the pelvis and lower limbs, 45% in the spine, and 17% in sternum and ribs). 10% of patients had a diffused pattern, 4% had the salt and pepper pattern, and 6% had a normal pattern.
On WBLDCT, 30% of patients presented with osteolysis (focal/combined pattern) with a total of 206 lytic lesions detected (33% in the skull, 10% in the upper limbs, 12% in pelvis and lower limbs, 45% in the spine, and 16% in sternum and ribs). 8% of patients had a diffuse pattern and 6% with no bone involvement. WBLDCT also detected 10 hyperattenuating lesions not recognisable to WBMRI. Moreover, 9% of patients presented an extraosseous involvement, which only WBRMI was able to detect.
Conclusion: WBLDCT is a reliable imaging technique able to detect small lytic lesions which are difficult to detect in MRI, such as skull lesions and hyperattenuating lesions. Conversely, WBMRI is more specific in discriminating diffuse bone involvement and detecting extraosseous disease.

Iodine concentration of healthy lymph nodes of the neck, axilla, and groin in dual-energy CT

A. Sauter[1], S. Ostmeier[1], J. Nadjiri[1], D. Deniffel[2], E. J. Rummeny[1], D. Pfeiffer[1];
[1]Munich/DE, [2]Toronto, ON/CA (ostmeiersophie@gmail.com)

Purpose: Lymph nodes (LN) are examined in every CT scan. Until now, an evaluation is only possible with morphological criteria. With dual-energy CT (DE-CT) systems, iodine concentration (IC) can be measured which could conduct an improved evaluation. The purpose of the study was to define standard values for IC of cervical, axillary, and inguinal LN in DE-CT, as these do not yet exist despite their clinical relevance.
Methods and materials: Imaging data of 297 patients who received a DE-CT in a portal-venous phase and showed healthy LN was retrospectively collected from the institutional PACS system. No present history of malignancy, inflammation, or trauma in the examined region was present. For each patient, the IC of the 3 largest LN of the examined area was measured. Normalisation to different structures was performed.
Results: The normalisation of the IC of LN to artery, vein, muscle, or a combination of those, did not lead to a decreased value-range. The smallest range and confidence interval of IC was found when using absolute values of IC for each region. Hereby, the mean values (95% confidence interval) for IC of LN were found: 2.09 mg/ml (2.00-2.18 mg/ml) for the neck, 1.24 mg/ml (1.16-1.33 mg/ml) for the axilla, and 1.11 mg/ml (1.04-1.17 mg/ml) for the groin.
Conclusion: The current study suggests standard values for IC of LN in DE-CT which could be used to differentiate between healthy and pathological lymph nodes.
Limitations: IC could be affected by the used CT-protocol.
Ethics committee approval: The retrospective study was approved and conducted in accordance with the guidelines of the institutional review board. Informed consent was waived by the institutional review board due to the retrospective design of the study.

Feasibility of MRI/DWI for the evaluation of treatment response in multiple myeloma: can ADC values predict treatment response?

A. Paternain Nuin, P. Malmierca Ordoqui, A. Ezponda Casajus, J. J. Rosales Castillo, M. Calvo Imirizaldu, M. Elorz, M. J. Garcia-Velloso, J. D. D. Aquerreta Beola*; Pamplona/ES (alberpanu@gmail.com)*

Purpose: To analyse the feasibility of diffusion-weighted MRI (DWI) for predicting treatment response in multiple myeloma (MM) lesions compared to FDG PET-CT.
Methods and materials: 20 patients with MM undergoing same-day whole-body MRI and FDG-PET/CT for the evaluation of treatment response were retrospectively recruited. Overall, 63 whole-body MRIs were evaluated. 3 significant bone lesions were analysed for each patient. Quantitative analysis of ADC maps and SUVmax of each lesion were evaluated in the subsequent studies. Variation of ADC values was compared with the variation of SUVmax for each lesion, which was considered the reference standard for this study. Differences between the mean ADC value in lesions from patients with clinical progression and patients with treatment response were also analysed, considering the criteria of the international myeloma work group (IMWG). Data analysis was performed using SPSS 21.0 software (Spearman's rank correlation coefficient and Student's t-test). Two-tailed p values were used for all statistical assessment and $p<0.05$ was considered statistically significant.
Results: An inverse, high, and significant correlation between the variations of the ADC value and SUVmax ($r=-0.686$; $p<0.01$) was found. There were also significant differences in mean ADC values between lesions from patients with clinical progression and patients with treatment response (757.69 vs 1377.95, $p<0.01$).
Conclusion: Variations of ADC values in DWI can be used to assess treatment response in patients with MM.
Limitations: A retrospective study limited to a single centre and MRI protocol. The sample consisted of 20 patients in advanced stages.

Dual-energy CT virtual non-calcium technique in the diagnosis of osteoporosis: a correlation study with quantitative CT

Z. Liu, Y. Zhang, Y. Jiang*; Xi'an/CN (00505014@163.com)*

Purpose: To evaluate the diagnostic value for osteoporosis of dual-energy CT (DECT) based on the virtual non-calcium (VNCa) technique.
Methods and materials: Prospective dual-energy CT scanning was performed on the lumbar region of 55 patients with chronic low back pain, with a standard QCT phantom placed at the waist during scanning. Using the QCTPro analysis system, the BMD of each vertebral body was measured. Based on the VNCa technique, the quantitative parameters were measured, including the CT value of calcium (contrast media, CM), CT value of mixed energy images (regular CT value, rCT), calcium density(CaD), and fat fraction (FF), by using Siemens dual-energy analysis software with a specially modified configuration file. Pearson's test was used to analyse the correlation between BMD and these parameters, and to establish a regression equation. The diagnostic efficiency for osteoporosis of the equation was evaluated by ROC curve.
Results: The CM, rCT, CaD, and FF were significantly correlated with BMD (r-values were 0.885, 0.947, 0.877, and 0.492, respectively, and all $P<0.01$), the regressive BMD (rBMD) could be expressed with an equation as $rBMD=54.82-0.19*CM+20.03*CaD-1.24*FF$. Taking $rBMD<81.94 mg/cm^3$ as the threshold, the sensitivity and specificity were 90.0% and 92.0%, respectively, and the AUC was 0.966 ± 0.009 ($P<0.01$).
Conclusion: The calcium and fat quantitative related parameters of DECT have a good correlation with the BMD measured by QCT, and it may serve as an alternative method for the quantitative evaluation of osteoporosis in terms of mineral content and bone marrow fat composition.
Limitations: We try our best to ensure ROI "point-to-point" correspondence to reduce the generation of system errors.
Ethics committee approval: This research was approved by the Ethics Committee of Xi'an Jiaotong University Affiliated Honghui Hospital.

3D calcium maps of bone mineral density using spectral photon-counting CT

A. Matanaghi[1], C. Leary[2], P. Walker[1], M. Rajeswari Amma[1], J. Clark[1], N. Gilchrist[1], A. Y. Raja[1], A. P. H. Butler[1], M. Collaboration[1]; *[1]Christchurch/NL, [2]Portland, OR/US (aysouda.matanaghi@postgrad.otago.ac.nz)*

Purpose: We assessed 3-dimensional changes to bone-mineral density during decalcification and fracture healing processes. Characterising these changes has direct relevance to a wide range of clinical situations including fracture risk, bone healing, and other diseases affecting bone.
Methods and materials: 3D calcium maps at 90 µm voxel size were obtained using a MARS spectral photon-counting CT. Measured calcium densities ranged from 0-1200 mg/ml.
In a decalcification study, 4 excised ovine femur bones were demineralised in 2.5% nitric acid at different time intervals (0, 3, 6, and 16 days). Atomic absorption spectrometry was performed on 251 times diluted nitric acid solution (collected at each interval) and compared with MARS 3D calcium maps of the biological sample.
In a fracture healing study, 4 sheep were administered strontium daily until sacrifice at week 2, 4, 6, and 8 after an induced fracture. Excised tibias were scanned and mineral content values from MARS were compared with DXA.
Results: For decalcification, measured cortical BMD and total BMD (on 100 slices) decreased across the time 880 ± 170 to 440 ± 200 mg/cm^3 and 410 ± 230 to 213 ± 180 mg/cm^3, respectively. The trend was consistent with the atomic absorption spectrometry measurements of calcium loss into the nitric acid solution.
In assessing bone healing, MARS calcium maps show an increasing trend in cortical bone-mineral content as the fracture heals in all 4 sheep (1.04, 1.17, 1.31, and 1.72g). Total bone mineral content measurements with MARS and DXA correlated within 5 and 8% of each other.
Conclusion: Spectral photon-counting CT with a MARS scanner can quantify and visualise in 3D the changes in bone mineralisation. This will impact research, diagnosis, and management of a wide range of bone conditions.
Limitations: n/a

Accuracy, precision, and reliability of bone mineral density (BMD) measurements by dual-energy CT (DECT): an initial ex-vivo study

L. Qin, F. Yan, L. Du*; Shanghai/CN (tevez10@126.com)*

Purpose: To investigate the accuracy, precision, and reliability of volumetric bone mineral density (vBMD) derived by dual-energy CT (DECT).

Methods and materials: 23 patients who underwent total hip arthroplasty were enrolled. Femoral heads were excised to rectangles for scanning. A dual-source DECT scanner (Definition flash, Siemens) was used to create dual-energy images under 80/Sn140 and 100/Sn140 kVp scanning conditions. They were subsequently scanned by single-energy CT and dual-energy x-ray absorptiometry (DEXA) to produce QCT-vBMD and BMM (bone mineral mass), respectively. DECT images were loaded to post-processing workstation (Examine, Siemens) for the calculation of DE-vBMD and BMM.
Results: At both scanning protocols conditions, DE-vBMD was excellently correlated with QCT-vBMD. Similarly, DE-BMM was strongly correlated with QCT-BMM and DEXA-BMM. Substantial agreement was found between QCT-BMM and DEXA-BMM. Agreement of interobserver and intraobserver of DE-vBMD was also good. Higher DECT-derived vBMD was found under 100/Sn140 kVp. Under 80/Sn140 kVp, DECT-derived vBMD and BMM were significantly higher than those from QCT and DEXA, with a mean difference that ranged from 7.8% to 57.6% for DE-vBMD, and 5.6% to 36.3% for DE-BMM, respectively. Linear regression analysis was carried out to calibrate 80/Sn140 kVp DE-vBMD (=0.6×DE-vBMD+48.493).
Conclusion: DECT allows for vBMD and BMM, which were strongly correlated with measurements derived from QCT and DEXA with high reliability and precision. Furthermore, after linear regression calibration, DECT could potentially provide accurate vBMD and BMM, and opportunistic screen patients undergoing DECT for other clinical indications.
Limitations: No DECT examinations were performed before surgeries. The assessment of osteoporosis was generally performed in the lumbar vertebrae. Whether contrast-enhancement DECT had impact on the measurements was unknown.
Ethics committee approval: Approved by the institutional review board of our institution. Written informed consent was obtained.
Funding: No funding was received for this work.

MRI patterns indicate treatment success and tumour relapse following radiofrequency ablation of osteoblastoma

L. Kintzelé[1], S. C. Brandelik[1], F. Wuennemann[1], M.-A. Weber[2], B. Lehner[1], H.-U. Kauczor[1], C. Rehnitz[1]; [1]*Heidelberg/DE,* [2]*Rostock/DE (kintz_l@hotmail.com)*

Purpose: To explore the typical magnetic resonance imaging (MRI) pattern of osteoblastoma (OB) after radiofrequency ablation treatment (RFA) and to derive signs that indicate treatment success or relapse.
Methods and materials: A total of 43 follow-up MRI examinations on 15 OB patients that underwent a total of 19 RFAs were analysed retrospectively. An early follow-up group (1-4 months after RFA) and late follow-up group (8-131 months after RFA) were created. Groups were differentiated depending on clinical treatment success. Images were analysed for the presence of central nidus enhancement (CNE), peripheral nidus enhancement (PNE), perifocal bone marrow oedema (PBME), and fatty nidus conversion (FNC).
Results: Every patient (n=14/14) in the treatment success group showed a target-like appearance with negative CNE and positive PNE or PBME at early follow-up. PNE was present in 93% (n=13/14) and PBME in 71% (n=10/14) of early follow-up images. At late follow-up, the target-like appearance was observed in 25% (n=5/20) of exams and 20% (n=4/20) for both PNE and PBME. FNC was not observed at early follow-up but occurred in 55% (n=11/20) of late follow-up exams. All three included MRI exams at clinical recurrence showed strong CNE, PNE, and extensive PBME in contrast to exams of the treatment success group.
Conclusion: The target-like appearance of OB indicates treatment success in early follow-up MRI exams. PNE and PBME typically reduce over time and can lead to FNC in successfully treated patients. CNE recurrence with PNE and extensive PBME are signs of relapse. PNE and PBME do not indicate treatment failure at early follow-up.
Limitations: The retrospective study design and limited patient number due to the rareness of osteoblastoma.
Ethics committee approval: The study was performed with a waiver of informed consent by the local review board.
Funding: No funding was received for this work.

Benign versus malignant soft tissue tumours: differentiation with 3T MR texture analysis including intravoxel incoherent motion diffusion-weighted imaging

Y. Lee[1], W.-H. Jee[1], Y. Hwang[1], Y.-G. Chung[2], W.-J. Bahk[1]; [1]*Gyeonggi/KR,* [2]*Seoul/KR*

Purpose: To investigate the value of MR texture analysis (TA) to differentiate malignant from benign soft tissue tumours at 3T MRI including IVIM DWI.
Methods and materials: 69 patients with pathologically confirmed soft tissue tumours (29 benign and 40 malignant) who underwent 3T MRI including IVIM DWI were retrospectively enrolled. TA was performed on axial T1WI, T2WI, CET1, high-b value DWI, and ADC map using software (TexRAD). Mean, SD, entropy, MPP, skewness, and kurtosis were calculated according to different Laplacian of Gaussian spatial filters: SSF 0, 2, 4, and 6. The ROC curve was obtained. Student's t-test and multivariate logistic regression analysis were performed. The ROC curve with AUC was obtained.
Results: SSF 4 showed overall higher AUCs than other SSFs, although there were no significant differences in different SSFs. AUCs of the mean of DWI, ADC, T2WI, and CET1 were 0.709 (95% CI, 0.586-0.831), 0.851 (0.751-0.951), and 0.772 (0.656-0.887), which were significantly different between benign and malignant soft tissue tumours ($p<0.05$). AUCs of kurtosis of DWI, T1WI, and CET1 were 0.748 (0.632-0.864), 0.732 (0.610-0.855), and 0.806 (0.700 -0.913), which were significantly higher in malignant tumors ($p<0.05$). AUCs of entropy of DWI, ADC, and T2WI were 0.763 (0.653-0.874), 0.763 (0.653-0.874), and 0.769 (0.657-0.880), which were significantly higher in malignant tumours ($p<0.05$). AUCs of MPP of ADC and CET1 were 0.734 (0.605-0.864) and 0.744 (0.624-0.864), which was significantly lower in malignant tumours ($p<0.05$). AUC of combined ADCmean and CEkurtosis was 0.883 (0.783-0.943) with a sensitivity and specificity of 83% and 86%.
Conclusion: MR TA may be reliable and accurate in differentiating malignant from benign soft tissue tumours at 3T including IVIM-DWI.
Limitations: A retrospective study with selection bias and relatively small study population.
Ethics committee approval: Approved by IRB and informed consent was waived.
Funding: No funding was received for this work.

MR imaging-guided high intensity focused ultrasound for painful bone metastases: standard versus dedicated conformal bone system

C. Gasperini[1], M. P. P. Aparisi Gomez[2], P. Ghanouni[3], T. Frisoni[1], D. Donati[1], A. Napoli[4], A. Bazzocchi[1]; [1]*Bologna/IT,* [2]*Valencia/ES,* [3]*Stanford/US,* [4]*Rome/IT (chr.gasperini@gmail.com)*

Purpose: MR-imaging-guided high intensity focused ultrasound (MRgHIFU) is a treatment option for painful bone metastases. A bone-dedicated system has been developed (conformal bone system (CBS)) aiming at extended treatment approaches and increased patient comfort. The purpose of this work was to compare CBS with the conventional system (CS) in terms of safety and efficacy.
Methods and materials: A matched-pair analysis study was conducted to compare the therapeutic effects of the two systems. CBS and CS-treated groups were matched 1:1 by age, sex, pre-treatment pain score on the NRS, and treated site. The primary endpoint was the rate of response to treatment (complete and partial) at 3 months after treatment according to the international consensus on palliative radiotherapy endpoints for future clinical trials in bone metastases criteria. Secondary endpoint included the rate of major and minor complications according to the common terminology criteria for adverse events, version 5.0.
Results: According to the criteria for patient eligibility and matching, a total of 28 patients (14 CBS,14 CS) with bone metastasis were enrolled for analyses (mean age: 61 in CBS group, 57 in CS group); 57% were male and 43% were female. Results showed that both CBS and CS were effective. The mean NRS at baseline was 6.7±2.6 and 6.5±2.8 for CBS and CS group, respectively. The primary endpoint occurred in 12 patients in the CBS group and in 10 in the CS group (cumulative event rate 86% vs 71%, p=0,6483). No adverse events over grade 2 were documented in both groups.
Conclusion: CBS provides a similar overall treatment response rate compared to CS and is equally safe. With this study we enhanced its feasibility for painful bone metastasis in selected patients.
Limitations: The small sample size and limited follow-up period to report clinical responses.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Treatment effects on osteoporotic vertebral compression fractures: a clinical long-term study of pain evaluation after vertebroplasty and kyphoplasty

T. J. Vogl, C. Hackbarth, N. N. N. Naguib; *Frankfurt am Main/DE*
(t.vogl@em.uni-frankfurt.de)

Purpose: To evaluate treatment effects on osteoporotic vertebral compression fractures (VCFs) by using percutaneous vertebroplasty (PFP) and percutaneous kyphoplasty (PKP) and to document whether these effects are still detectable several years after the end of therapy.
Methods and materials: From January 2002-February 2015, 49 patients who received PVP or PKP were evaluated. The surgical protocols and radiologically assisted CTs were retrospectively evaluated related to the occurrence of cement leakage. A special questionnaire regarding pain development before and after the procedure was analysed prospectively. The measurement of pain quality was based on the visual analogue scale (VAS).
Results: VAS score was on average 7.0 before and 3.7 after therapy with a significant difference (p≤0.001) in the change of VAS scores in all patients. Considering the reduction of VAS over time of observation, there was no significant difference in the occurrence of symptoms (p=0.694) and no difference in the decrease in VAS over time. In 10 patients (22.73%), at least one cement leakage was recorded by CT scan. There was no significant difference in the occurrence of cement leakage and the change in VAS (p=0.146). After therapy, 79.6% of all patients reported an increase in mobility and 83.7% reported a rise in quality of life.
Conclusion: Both PVP and PKP significantly reduce the pain in VCFs. These results are still being observed more than 10 years after the end of treatment.
Limitations: Other interventions overlapped with the therapeutic approach documented here. Evaluation of pain before and after therapy was based on the subjective feelings of the individual patients. Comparison with non-surgical fracture treatment or a placebo group is missing.
Ethics committee approval: This study was approved by our local ethical committee. Written informed consent was obtained.
Funding: No funding was received for this work.

Diffusion-weighted magnetic resonance and T1 heterogeneity predicts the response to treatment in sarcomas

D. Moreno Martínez[1], A. Gimeno[2], I. Ramos Oliver[2], M. de Albert de Delas-Vigo[2], C. Torrents[2], L. Casas[2], J. M. M. Escudero Fernández[2], R. Dominguez[2], M. T. Veintemillas[2]; [1]*Cornella de Llobregat/ES,* [2]*Barcelona/ES*
(daniel.mm@icloud.com)

Purpose: To identify MRI findings, pathological findings, and tumour-related factors that predict the response to treatment and its association with survival of soft tissue sarcomas.
Methods and materials: 41 patients with 23 complete cases were retrospectively analysed. All patients had a multiparametric MRI 1.5T, including conventional (T1-weighted, T2-weighted, and contrast-enhanced T1-weighted imaging) and functional (DCE-MR imaging and DW imaging with ADC mapping) sequences at the diagnoses, from 2011-2018. The analysis was done from the diagnosis MRI until the last MRI, chest-CT, or death. ADC values were reported using global regions of interests (gROIs) including all the tumuor in one slide and specific ROIs (sROIs) in the areas of lower ADC values. Other data was also reported (T1-T2 heterogeneity, presence of blood or fat, and contrast enhancement type). Pathological data after the percutaneous biopsy and the resected specimen was reported.
Results: Higher values of gROIs were related with less mortality (p=0.03) and less fibrosis post-treatment (p<0.05). Higher sROIs values were related with more fibrosis post-treatment (p=0.02) and less mortality (p=0.01). Higher T1-heterogeneity was related to less fibrosis post-treatment (p<0.05). We also found that higher values of fibrosis post-treatment were related to less mortality.
Conclusion: Higher values of diffusion are related to less mortality and the absence of areas with low ADC values are related to a good response to therapy. Higher values of T1-heterogeneity are related to a bad response to treatment (less fibrosis post-treatment). There is a positive association with fibrosis post-treatment and survival.
Limitations: The subjective reporting of the non-quantitative data and that not all patients had all data.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Bone marrow oedema detection using dual-energy CT: application in sacroiliitis

M. Chen[1], J. L. Jaremko[2], F. van Den Bosch[1], N. Herregods[1], P. Carron[1], D. Elewaut[1], L. B. O. Jans[1]; [1]*Ghent/BE,* [2]*Edmonton, AB/CA*
(Min.Chen@ugent.be)

Purpose: To evaluate the diagnostic performance of dual-energy computed tomography (DECT) for sacroiliac bone marrow oedema (BME) detection in patients suspected for spondyloarthritis.
Methods and materials: Patients aged 18-55 years with suspicion for spondyloarthritis underwent DECT and 3.0 Tesla MRI of the sacroiliac joints on the same day. Virtual non-calcium (VNCa) images were calculated from DECT images for BME detection, using a three-material decomposition algorithm for bone mineral, red bone marrow, and yellow bone marrow. Each sacroiliac joint was divided into four quadrants for analysis. VNCa images were scored by two readers independently: 0=normal bone marrow and 1=BME. A quadrant was recorded as BME present if either of the readers scored '1' for the quadrant. Diagnostic performance was assessed with reference to MRI. CT numbers were measured on VNCa images. ROC analyses were performed to determine the cut-off values for BME detection.
Results: 40 patients (16 men, 24 women) were included. The sensitivity and specificity of BME detection by DECT were 65.4% and 94.2%. AUCs for CT numbers in the ilium and sacrum were 0.90 and 0.87, respectively. Cut-off values of -44.4 HU (iliac quadrants) and -40.8 HU (sacral quadrants) yielded sensitivities of 76.9% and 76.7% and specificities of 91.5% and 87.5%, respectively.
Conclusion: VNCa images are useful for BME detection in patient suspected for sacroiliitis.
Limitations: The sample size of the present study is small and the prevalence of BME is relatively low. The final clinical diagnosis was not taken into consideration for analysis.
Ethics committee approval: Institutional review board approved this study. Written informed consent was obtained.
Funding: The study is partially funded by the Young Researchers Grant awarded by the European Society of Musculoskeletal Radiology.

A novel computed tomography-based scoring system of intra-articular mineralisation of the knee: BUCKS (Boston University calcium knee score)

M. Jarraya[1], T. Neogi[1], J. Lynch[2], D. T. Felson[1], M. Nevitt[2], A. Guermazi[1]; [1]*Boston, MA/US,* [2]*San Francisco, CA/US*
(mohamedjarraya@gmail.com)

Purpose: To describe and assess the reliability of a novel computed tomography (CT) scoring system, the Boston University calcium knee score (BUCKS), for evaluating intra-articular mineralisation.
Methods and materials: We included subjects from the multicenter osteoarthritis study (MOST), a NIH-funded longitudinal cohort of older adults with or at risk of knee OA. Subjects underwent CT of bilateral knees. Each knee was scored at 28 locations (14 cartilage, 6 meniscus, 6 ligaments, 1 joint capsule, and 1 vessel). A musculoskeletal radiologist scored cartilage, meniscus, and vascular features using a score from 0-3. The joint capsule, posterior meniscal roots, ACL/PCL, and collateral ligaments were scored 0 or 1. 31 subject CTs

were reread 12 weeks later by the same reader and by a second reader, and agreement was evaluated using weighted kappa.
Results: The intra-reader reliability ranged from 0.93 for ligaments to 1.0 for joint capsules. The inter-reader reliability ranged from 0.92 for cartilage to 1.0 for joint capsules.
Conclusion: BUCKS demonstrated excellent reliability and is a potentially useful CT-based tool for studying the role of calcium crystals in knee OA.
Limitations: The concern for radiation exposure and inability to distinguish between the different types of calcium crystals.
Ethics committee approval: This study was approved by the institutional review boards at the University of Iowa, University of Alabama, Birmingham, University of California, San Francisco, and Boston University Medical Center.
Funding: The MOST Study is supported by NIH grants from the National Institute on Aging to Drs. Lewis (U01-AG-18947), Torner (U01-AG-18832), Nevitt (U01-AG-19069), and Felson (U01-AG-18820). This study was also supported by Dr. Neogi (K24 AR070892) and P60 AR047785.

Angulation neutralising gyrating evaluation line-up (ANGEL) rib reconstructions in low-dose thoracic CT examinations of myeloma patients
J. Neubauer, L. Waibel, I. Dietrich, C. Neubauer*; Freiburg/DE*

Purpose: To compare reporting time and diagnostic accuracy for osteolysis between angulation neutralising gyrating evaluation line-up (ANGEL) rib reconstructions and standard axial reconstructions in low-dose thoracic CT examinations of myeloma patients.
Methods and materials: This retrospective study included myeloma patients who underwent low-dose thoracic CT examinations in our institution over a 1 year period. ANGEL rib and standard axial reconstructions were calculated. DICOM files were anonymised. 2 radiologists (3 years experience) independently evaluated osteolysis for each rib and measured the reporting time. Two radiologists (>6 years experience) established the reference standard using all reconstructions available. For differently evaluated cases, consensus reading was performed. P<0.05 was considered to denote statistical significance.
Results: 49 consecutive patients were included. Reporting time for ANGEL rib reconstructions and standard axial reconstructions were 97s and 80s for reader 1 (P=0.04) and 310s and 219s for reader 2 (P<0.001). Sensitivity, specificity, PPV, and NPV of ANGEL rib reconstructions and standard axial reconstructions for osteolyses were 0.52, 0.95, 0.61, 0.93 and 0.54, 0.94, 0.57, 0.94 for reader 1 (P>0.63) and 0.43, 0.96, 0.60, 0.92 and 0.53, 0.99, 0.97, 0.94 for reader 2 (P<0.04).
Conclusion: Reading time was longer in ANGEL rib reconstructions. Diagnostic accuracy of ANGEL rib reconstructions was worse in one reader and the same in the other. ANGEL rib reconstructions, therefore, cannot substitute standard axial reconstructions.
Limitations: This is a retrospective study. The reference standard was established by two experienced radiologists, partly using consensus reading.
Ethics committee approval: Our ethics committee approved this study.
Funding: No funding was received for this work.

CTPA with a conventional CT at 100 kVp versus a spectral-detector CT at 120 kVp: a comparison of radiation exposure, diagnostic performance, and image quality
A. Sauter[1], N. Shapira[2], F. K. Kopp[1], J. K. Aichele[3], J. H. W. Bodden[1], A. Knipfer[1], J. Nadjiri[1], E. J. Rummeny[1], P. B. Noel[4]; *[1]Munich/DE, [2]Haifa/IL, [3]Pfaffenhofen/DE, [4]Philadelphia, PA/US (andreas.sauter@tum.de)*

Purpose: Dual-energy CT systems are nowadays widely used in clinical routine. However, concerns regarding radiation dose exist and quality of virtual-monoenergetic imaging with low kVp-levels compared to real low-kVp imaging is of interest. The purpose of this study was to compare CT pulmonary angiographies (CTPAs) as well as phantom scans obtained at 100 kVp to virtual monochromatic images (VMI) obtained with a spectral detector CT (SD-CT) at equivalent dose levels.
Methods and materials: 60 patients with suspected pulmonary embolism (PE) were included using a conventional CT (C-CT) and a SD-CT with the same mean CT dose index (4.85 mGy), respectively. C-CT was performed with 100 kVp and SD-CT was performed with 120 kVp. For SD-CT, VMIs with 40, 60, and 70 keV were calculated. All datasets were evaluated by three blinded radiologists regarding image quality, diagnostic confidence, and diagnostic performance. The contrast-to-noise ratio (CNR) for different iodine concentrations was evaluated in a phantom study.
Results: CNR was significantly higher with VMI at 40 keV compared to all other datasets. Subjective image quality, as well as a sensitivity and specificity, showed the highest values with VMI at 60 keV and 70 keV. A significant difference to 100 kVp (C-CT) was found for image quality. The highest sensitivity was found using VMI at 60 keV.
Conclusion: Higher levels of diagnostic performance and image quality were achieved with SD-CT compared to C-CT. In the clinical setting, SD-CT may be the modality of choice as additional spectral information can be obtained.
Limitations: As two different CT-systems were compared, examinations of different patients had to be compared and results could be biased.
Ethics committee approval: Institutional review board (IRB) approval was obtained for this retrospective study.
Funding: No funding was received for this work.

Dual-energy CT in patients with suspect acute pulmonary embolism: a diagnostic accuracy systematic review and meta-analysis
A. Cozzi[1], C. B. Monti[1], M. Zanardo[1], S. Schiaffino[2], F. Sardanelli[1], F. Secchi[1]; *[1]Milan/IT, [2]San Donato Milanese/IT (andrea.cozzi@gmail.com)*

Purpose: To review the diagnostic performance of dual-energy CT (DECT) in diagnosing acute pulmonary embolism (PE).
Methods and materials: The study protocol was registered on PROSPERO and reported according to PRISMA. In February 2019, a systematic search was performed on MEDLINE/EMBASE for articles reporting the diagnostic performance of DECT for acute PE. Pooled sensitivity, specificity, positive and negative likelihood ratios (LR), and diagnostic odds ratio (DOR) were calculated according to the approach by Reitsma. A summary receiver operating characteristics (sROC) curve was constructed. Data was reported as an estimate and 95% confidence interval (CI). The pooled effective radiation dose for the chest (ChERD) was calculated using the random effect model. The impact of the year of publication on ChERD was evaluated through meta-regression analysis and risk of publication bias was assessed using the Egger test.
Results: Of 159 initially retrieved articles, 14 were included (23 independent study parts), totalling 993 patients with a median age range of 40-68 years and males from 32 to 79%. 12 studies used dual-tube/dual-detector DECT and 2 rapid-kV-switching DECT. Lower voltages ranged from 80-100 kVp and high voltages from 135-140 kVp. Pooled sensitivity was 84.1% (95% CI 78.3−88.6%), specificity 88.6% (95% CI 83.9−92.1%), positive LR 7.52 (95% CI 5.21−10.60%), negative LR 0.18 (95% CI 0.13−0.25%), and DOR 42.8 (95% CI 24.2−70.3%). The area under the curve of sROC was 0.93. ChERD showed high heterogeneity (I^2=97%) with 4.52 mSv (95% CI 3.68−5.36 mSv) pooled estimate. At meta-

regression, the year of publication did not impact on the radiation dose (r=0.152, p=0.703). The risk of publication bias was significant (Egger test p=0.006).
Conclusion: DECT diagnostic performance in acute PE is comparable to that of single-energy CT with comparable ChERD.
Limitations: Non-uniform use of DECT and reader experience.
Ethics committee approval: No Ethics Committee approval needed.
Funding: No funding received for this work.

RPS 1404b-3 11:27

The feasibility and diagnostic performance of a contrast-enhanced ultra-low-dose CT protocol with a reduced scan range at 0.56 mSv on a 3rd generation dual source scanner to detect pulmonary embolism

A. B. Brendlin, S. Afat, K. Nikolaou, A. Othman*; Tübingen/DE (andreas.brendlin@gmail.com)*

Purpose: To evaluate the feasibility of a contrast-enhanced ultra-low-dose (ULD) protocol with reduced scan range (RSR) in patients with clinically suspected pulmonary embolism (PE) compared to ULD at original scan range (OSR).
Methods and materials: We included 82 consecutive patients (64 ± 16 years; 45 women) on a 3rd generation dual-source-scanner. Realistic simulations were used to generate datasets with 25% radiation dose OSR using ADMIRE 3 and 5, and 25% RSR ADMIRE 3 and 5, resulting in 328 datasets (4 sets each). Image noise was defined as mean standard deviation of HU-values measured bilaterally in the paraspinal muscles. The effective radiation dose was compared. All datasets were reviewed by three radiologists independently for image quality, diagnostic confidence, and presence/absence of PE. The diagnostic accuracy of ULD-RSR datasets was calculated using original dose datasets as a reference standard.
Results: Image noise between 100% OSR (20.54 ± 3.37), 25% Admire 3 (16.31 ± 2.58), and 25% Admire 5 (12.19 ± 2.71) differed significantly ($p \leq 0.001$). At 0.56 mSv, the effective radiation dose of ULD-RSR was significantly lower than standard protocol (3.55 mSv), as well as for either ULD or RSR alone ($p \leq 0.001$). Image quality was outstanding in each category (5; IQR 4-5) with excellent reliability (ICC ≥ 0.814, 95%CI 0.731-0.875). There was no impairment by reduction of scan range or radiation dose ($p \geq 0.54$). The sensitivity of ULD-RSR-CT was 0.947 and specificity 0.981.
Conclusion: On a 3rd generation dual-source-scanner, the radiation dose can be reduced to 16% of the original dose (0.56 mSv) in the detection of PE by combining mAs-reduction with a reduction of scan range and iterative reconstruction, while maintaining excellent image quality and accuracy.
Limitations: A retrospective design.
Ethics committee approval: Local ethics committee approved.
Funding: No funding was received for this work.

RPS 1404b-4 11:33

Prevalence and patterns of lung disease in patients with vascular Ehlers Danlos Syndrome (vEDS): CT features and histological correlations

S. Boussouar[1], A. Benattia[1], L. Gibault[1], F. Capron[1], P.-Y. Brillet[2], P. A. Grenier[1], M. Frank[1], E. Mousseaux[1], O. Sanchez[1]; *[1]Paris/FR, [2]Bobigny/FR (samia.boussouar@aphp.fr)*

Purpose: To describe and characterise clinical and CT imaging of lung involvement in patients with vEDS.
Methods and materials: All consecutive vEDS patients referred to a tertiary referral centre for vEDS between 2000 and 2016 were included. Chest computed tomography (CT) scans performed at initial vascular workup were retrospectively reviewed by two chest radiologists for lung involvement and analysed in respect of medical history and type of variant. 5 histologic samples from surgery were analysed.
Results: 136 patients (83 females and 53 males, 37 years) with molecularly confirmed vEDS were included. Identified pathogenic variants were glycine substitutions in 83 (61%) patients, splice-site and in-frame insertions-deletions in 42 (31%), and variants leading to haploinsufficiency in 11 (8%). 49 (36%) patients were current or former smokers. 24 (17.6%) patients had a history of respiratory complications including pneumothorax (n=17), haemothorax (n=4), and haemoptysis (n=3) leading to thoracic surgery in 11 patients.
Lung abnormalities were detected in CT scans in 78 (57.3%) patients. Emphysema (mostly centrilobular and paraseptal) was identified in 44 (32.3%) patients, without significant differences between smokers and nonsmokers. Clusters of calcified small pulmonary nodules were present in 9 (6.6%) patients and cavitated nodules in 4 (2.9%). Histological samples from surgery showed emphysema lesions with disruptions of alveoli in 3 cases, accompanied by diffuse haemorrhage increased haemosiderinic resorption.
Conclusion: In patients with vEDS, the most frequent CT feature observed, even in asymptomatic patients, is emphysema areas, suggesting a rupture of the alveolar walls. The identification by radiologists of this pattern may facilitate the diagnostic screening of undiagnosed probands.
Limitations: A retrospective study. No respiratory functional examinations.
Ethics committee approval: Written informed consent.
Funding: No funding was received for this work.

Machine learning-based cardiac chamber segmentation in CTPA for the noninvasive detection of pulmonary hypertension

M. A. Fink, C. Melzig, B. Egenlauf, E. Grünig, H.-U. Kauczor, C. P. Heussel, F. Rengier*; Heidelberg/DE*

Purpose: To assess machine learning-based cardiac chamber segmentation in computed tomography pulmonary angiographies (CTPA) for the noninvasive detection of pulmonary hypertension (PH).
Methods and materials: 56 consecutive patients undergoing right heart catheterisation (RHC) with a measurement of mean pulmonary arterial pressure (mPAP) and CTPA for suspected PH within 3 weeks between 08/2013 and 09/2014 were retrospectively reviewed. Cardiac chamber segmentation was performed automatically by a machine learning-based commercially available software and manually corrected if deemed necessary. Cardiac chamber volumes (right and left ventricles (RV/LV) and right and left atria (RA/LA)) were indexed to body surface area.
Results: 37 patients were diagnosed with PH (mean mPAP 38±11 mmHg) and 19 patients had a normal mPAP (mean 17±4 mmHg). Manual correction of the segmentation was performed in 15 cases (27%). In patients with PH, RA, and RV were significantly enlarged (87±45 vs. 44±19 ml/m^2 and 102±39 vs. 63±23 ml/m^2) and right to left atrial and ventricular ratios significantly increased (1.8±0.9 vs. 1.1±0.4 and 2.7±1.4 vs. 1.4±0.4) (all $p<0.001$). AUCs for the detection of PH were 0.83, 0.85, 0.76, and 0.83 for RA, RV, and atrial and ventricular ratio, respectively. A cutoff value for RV of 63 ml/m^2 allowed the diagnosis of PH with sensitivity, specificity, and positive and negative predictive values of 87%, 74%, 86%, and 74%, respectively.
Conclusion: Machine learning-based automated cardiac chamber segmentation in CTPA allowed noninvasive detection of PH as confirmed by RHC with good diagnostic accuracy.
Limitations: A retrospective and single-centre study with a limited number of patients.
Ethics committee approval: Ethics committee approved study and waived written informed consent.
Funding: License for the segmentation software provided by Philips.

RPS 1404b-6 11:45

Machine learning model for predicting 30-day all-cause mortality in patients who were diagnosed with pulmonary embolism in the emergency department

N. Cahan[1], H. Greenspan[1], Y. Barash[2], S. Soffer[2], E. M. Marom[1], S. Apter[3], E. Konen[2], E. Klang[2]; *[1]Tel Aviv/IL, [2]Ramat Gan/IL, [3]Tel Hashomer/IL (noa.cahan@gmail.com)*

Purpose: Pulmonary embolism (PE) is a life-threatening condition. Rapid and accurate risk stratification can decrease PE mortality rates. We aimed to develop a machine learning 30-day mortality predictive model using clinical data.
Methods and materials: This retrospective study was approved by our institutional review board. We retrieved data for consecutive patients who underwent CT-angiography between 1/2012 to 12/2018 in our emergency department (ED) and were diagnosed with PE. Clinical variables included demographics, vital signs, chief complaint, medical history, home medications, blood tests, previous ED visits, and hospitalisations. The solution applies a machine learning-based classification algorithm, specifically, gradient boosting decision tree model (CatBoost). The model was trained on 2012-2017 data and tested on 2018 data. We evaluated the AUCs of single variables and of the entire model. We used Youden's index to find the model's optimal sensitivity and specificity.
Results: Our dataset included 367 patients, 38 of whom (10.3%) died within 30 days of diagnosis. Single variables with higher AUC included pulse (0.72), Di-Dimer (0.71), and arrival by ambulance (0.71). The entire model achieved an AUC of 0.84 (95% CI: 0.757-0.926) for predicting PE severity. 78.4% of the test cases were correctly risk stratified, based on the 30-day mortality label. Using Youden's index, the model showed a sensitivity of 90.9% and specificity of 77.7% for predicting death within 30 days.
Conclusion: Our model allows effective risk stratification of individuals with PE, which could improve the ability to direct preventative and health surveillance resources. To the best of our knowledge, the system is the first such fully automated solution.
Limitations: A retrospective single-centre study with a relatively small number of patients.
Ethics committee approval: Approved by our institutional review board.
Funding: No funding was received for this work.

Contrast medium administration for chest CT: a European protocol survey

M. K. Henning, T. M. Aaloekken, A. C. T. Martinsen, S. Johansen*; Oslo/NO (meid@ous-hf.no)*

Purpose: To investigate different contrast medium (CM) administration regimes for chest CT used by members of the European Society of Thoracic Imaging (ESTI).
Methods and materials: An online questionnaire was e-mailed to 650 ESTI members. The survey focused on CM protocols. In particular, questions referred to CM concentration, the use of fixed CM volume or weight/body composition tailored CM administration, injection rate, kV, and fixed delay or use of bolus tracking for chest CT.
Results: The overall response rate was 15.2%. Approximately 44% of the respondents used 350 mgI/ml and 54.5% used fixed CM volume regime. The injection rate varied between 1.5 to 5 ml/sec. Around 42% of respondents used fixed kV varying between 80 to 140 kVp and the majority used kV-modulation. Nearly 52% of the respondents used bolus tracking with a duration of 20-90 seconds.
Conclusion: Our survey showed a large variation in CM protocols used across Europe. There is a clear preference of using fixed CM administration regime for thoracic CT. More attention to the optimisation and establishment of a standard CM administration protocol in chest CT is needed.
Limitations: The name of the country and hospital were not recorded by the online survey. This may result in the involvement of several or no hospitals from each country responding to the survey. However, this cannot have such a major impact on the results achieved in this study as the aim of the study was to collect as many protocols as possible.
Ethics committee approval: The study was approved by the Norwegian Ethical Committee/Data Protection Officer at Oslo University Hospital.
Funding: No funding was received for this work.

RPS 1404b-8 11:57

An evaluation of breast shielding combined with low-dose CTPA protocol for use in pregnancy

C. D. Gillespie, A. Yates, M. Hughes, M. C. Murphy, M. Rowan, F. Ni Ainle, F. Bolster, S. J. Foley, P. J. Macmahon*; Dublin/IE (ayates989@gmail.com)*

Purpose: To determine if breast dose benefit can be obtained using in-plane bismuth breast-shields when combined with a low-dose CTPA protocol and to assess the impact on image quality.
Methods and materials: A low dose CTPA protocol was evaluated by phantom and patient study, using a 128 slice iterative-reconstruction and auto-modulation enabled CT-scanner with a limited scan range. A RANDO phantom scanned using three protocols (80, 100, and 20kv) and 20 patients undergoing low-dose CTPA in pregnancy were evaluated with and without bismuth breast-shields.
TLDs measured surface breast dose in patients and breast and uterine doses in the phantom at various gestations. Image quality was assessed by ROI-analysis of noise at shield level. Signal and contrast-to-noise-ratios and a subjective 5-point image-quality score were applied to patient CTPAs. Dose and image quality for low-dose CTPA alone was compared to low-dose CTPA protocol with shields.
Results: Phantom breast doses ranged from 0.84-2.26mGy without shield and 0.32-1.3mGy with shield, conferring 57% reduction in dose (range 39%-76%). Patients' average surface breast dose was 1.3mGy without shield (0.76-2.12mGy) and 0.68mGy (0.44-1.0mGy) with shields, conferring 48% reduction.
The phantom data demonstrates increased noise for shielding groups, the greatest for the lowest kV parameters. However, in the patient study both subjective quality scores, SNR (no-shield: 11.2±3.7, shield: 10.8±2.6, p=0.74), and CNR (no-shield: 10.0±3.3, shield: 9.3±2.4, p=0.6) were comparable between groups.
Foetal doses in the phantom study were highest at term (0.28, 0.86 and 1.4mGy at 80, 100 and 120kV) and ranged from 0.005-0.42mGy for trimester 1–3.
Conclusion: Combining low-dose CTPA protocols with breast-shielding confers additional breast dose savings of approximately 50% without significantly impacting image quality. This yields doses ranging from 0.4-1mGy, approaching doses quoted for low-dose-perfusion-only scintigraphy.
Limitations: A limited sample size.
Ethics committee approval: Ethics approval obtained.
Funding: No funding was received for this work.

RPS 1404b-9 12:03

Pseudo-embolic perfusion defects in pulmonary arterial hypertension (PAH) and pulmonary veno-occlusive disease (PVOD): evaluation with dual-energy CT lung perfusion in 63 patients

B. Lefebvre, M. Kyheng, N. Lamblin, P. Degroote, M. Fertin, J.-B. Faivre, J. Remy, M. Remy-Jardin*; Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To investigate the frequency and characteristics of PE-type perfusion defects in PAH and PVOD.
Methods and materials: 63 patients with PAH (n=51) and PVOD (n=12) underwent dual-energy CT in the diagnostic workup of pre-capillary PH. Chest CT angiography was obtained with a dual-source CT system (1st (n=2), 2nd (n=4), and 3rd (n=43) generation) and reconstruction of standard morphologic and lung perfusion images using the lung PVB software. Lung perfusion analysis included a quantitative (mg I/mL) and qualitative (segmental assessment of perfusion defect) evaluation completed by comparative analysis with morphologic images.
Results: In the overall study population: (a) lung perfusion was homogeneous in 22 patients (35%) and heterogeneous in 41 patients (65%), (b) when rated as heterogeneous, lung perfusion showed bilateral defects (41/41; 100%) with a mean percentage of 89.9% of segments with perfusion defects, and (c) there was a single type of perfusion abnormality (patchy defects: 16/41; 39%; nonsystematised hypoperfusion: 9/41; 22% or PE-type defects : 1/41; 2.4%) or a mixed pattern (15/41; 36.6%). Comparison between PAH and PVOD showed (a) no significant difference in the frequency of perfusion abnormalities (p=0.31), mean percentage of segments with abnormal perfusion (p=0.91), patchy defects per patient (p=0.23), or nonsystematised hypoperfusion (p=0.41), but (b) a higher proportion of segments with PE-type defects in PVOD (16.7% vs 2.3%; p=0.041). PE-type perfusion defects were seen in 8 patients (8/61; 12.7%) (PAH: n=5; PVOD: n=3), rated as mild (4/8) or marked (4/8), and seen with the concurrent presence of centrilobular micronodules/GGO (3/8), mosaic attenuation (4/8), or normal lung.

Conclusion: PE-type defects were identified in 12.7% of PAH/PVOD patients with morphologic abnormalities avoiding a misdiagnosis of CTEPH.
Limitations: n/a
Ethics committee approval: Waiver of patient informed consent.
Funding: No funding was received for this work.

Salvage of suboptimal enhancement of pulmonary artery in pulmonary CT angiography studies: rapid kVp switch dual-energy CT experience

A. Çinkooğlu, S. Bayraktaroğlu, R. Savas*; Izmir/TR (acinko@gmail.com)*

Purpose: To explore the potential improvement in pulmonary artery opacification and to assess the change in image quality parameters in VMI using fast switch kVp dual-energy CT.
Methods and materials: Computed tomography angiography (CTA) images of 877 patients with a diagnosis of PE were reviewed. 60 patients with suboptimal enhancement (<200 HU) were involved. Standard images (140 kVp) and VMI from 40 to120 keV were generated. Attenuation, noise, SNR, and CNR were measured in the pulmonary artery (PA). Using the VMIs, the best image was determined as the image with main PA opacification greater than 200 HU and image quality ≥3. 56 studies that met these criteria were considered as salvaged. At this best energy level, quantitative parameters were compared with standard images.
Results: The attenuations of VMIs at 40, 45, 50, 55, 60, 65, and 70 keV were significantly higher than standard images ($p< 0.001$). Similar findings were observed with SNR and CNR. In the salvaged patients, the average increase in mean PA attenuation was 62% (from 172.61±23.4 to 280.55±40.7), the average increase in SNR was 38% (from12.1±5.3 to 16.7±7.1), and the average increase in CNR was 48% (9.2±4.3 to 13.7±6) ($p< 0.001$).
Conclusion: Low keV VMI reconstructions significantly increase PA attenuation, CNR, and SNR compared to standard image reconstructions. Suboptimal CT studies can be salvaged using low keV VMIs.
Limitations: The study design is retrospective and includes a single-centre experience. To determine the adequacy of PA opacification level in CTA, we accepted a limit of 200 HU. There is no single predetermined standard value that can be used in this regard for pulmonary CTA.
Ethics committee approval: Approved by the Institutional Review Board(Approval Number:19-3.1T/70).
Funding: No funding was received for this work.

Application of the dual-layer spectral detector CT on CTPA with a low dose of iodine contrast agent and low injection rate

X. Sui[1], W. Song[1], Z. Y. Jin[1], H. Du[1], X. Lu[2], S. Yu[1]*; [1]Beijing/CN, [2]Shenyang/CN (lena_sui@vip.163.com)*

Purpose: To evaluate the feasibility of the dual-layer spectral detector CT on CTPA with a low dose of iodine contrast agent and low injection rate.
Methods and materials: 53 patients with suspected pulmonary embolism had a CTPA with 20ml 370 mg I/ml at 2ml/s. All chest CT examinations were performed using a dual-layer detector spectral CT unit. Two series of images were obtained, including conventional images at 120kVp and virtual monoenergetic spectral images at 40keV. The ROIs were placed at the main pulmonary arteries (PA) and right and left PA. The CNR, SNR, and image quality scores were compared at 120kVp and 40keV. The sensitivity, specificity, PPV, and NPV for the detection of pulmonary embolism were compared between conventional images and virtual monoenergetic spectral images at 40keV.
Results: CNR of main PA, right, and left PA at 40keV images were 24.3±43.3, 22.2±29.8, 22.6±30.3, and SNR were 26.4±44.5, 24.4±31.3, 24.7±31.8, respectively. CNR on conventional images were 5.9±6.1, 5.6±4.7, 5.7±4.9, and SNR were 7.6±7.0, 4.7±1.9, 7.2±5.7, respectively. CNR and SNR at 40keV were significantly higher than conventional images ($P<0.05$). Subjective image quality score of virtual monoenergetic images at 40keV was higher than conventional images but there was no significant difference (Z=-1.2, P=0.25). 26 patients showed PE. Compared with conventional images, the sensitivity, specificity, PPV, and NPV at 40keV were higher in the detection of pulmonary embolism.
Conclusion: Virtual monoenergetic images at 40keV on dual-layer spectral CT with a low dose of iodine and low flow rate increased the detection of PE, while preserving image quality. At the same time, it reduced the risks of contrast media-induced nephropathy and contrast agent extravasation.
Limitations: This is a small number study.

Dual-energy contrast-enhanced CT compared to lung perfusion scintigraphy to assess pulmonary perfusion in patients with severe emphysema

H. A. Gietema[1], K. Walraven[1], R. Posthuma[1], C. Mitea[1], D. J. Slebos[2], L. Vanfleteren[3]*; [1]Maastricht/NL, [2]Groningen/NL, [3]Gothenburg/SE (hester.gietema@mumc.nl)*

Purpose: Endoscopic lung volume reduction (ELVR) with endobronchial valves is a highly effective treatment for patients with severe emphysema, but treatment success depends on thorough patient selection. Next to high-resolution computed tomography (HRCT) of the lung parenchyma and the assessment of distribution in pulmonary perfusion is crucial in defining patient eligibility and target lobe selection. The latter is commonly performed with lung perfusion scintigraphy. We hypothesised that the iodine overlay calculated from contrast-enhanced dual-energy CT images added to the standard HRCT could provide appropriate perfusion estimates.
Methods and materials: 40 patients, screened for ELVR, were included in this analysis. Pulmonary perfusion was assessed with lung perfusion scintigraphy and dual-energy contrast-enhanced CT scans. Perfusion distribution was calculated for each lung and for the upper, middle, and lower thirds of both lungs with the planar technique. The same regions of interest (ROI) were chosen at the iodine overlay.
For each ROI mean, the difference in estimated perfusion was calculated and limits of agreement were assessed. For each patient, the mean absolute difference was for ROIs was calculated.
Results: Perfusion distribution over both lungs showed good correlation (r=0.8) but was significantly different between both techniques. ($p<0.001$). The mean difference for each selected ROI between lung perfusion scintigraphy and iodine overlay was -2,8% ±3.1% (right middle part) to 2,3% ± 3,8% (left lower part). Limits of agreement were -9% - 10%.
Limits of agreement of mean absolute differences per region of interest were 0.75-5.6%.
Conclusion: Quantification of perfusion distribution using planar 99mTc perfusion scintigraphy and iodine overlays calculated from dual-energy contrast-enhanced CTs correlates well with acceptable variability.
Limitations: Outliers and significant differences in pulmonary perfusion distribution were seen, for which further research is required.
Ethics committee approval: A waiver was received.

Intraoperative imaging findings in transcranial MR imaging-guided focused ultrasound treatment at 1.5T MRI

R. Cannella[1], C. Quarrella[1], M. D'amelio[1], A. Napoli[2], T. V. Bartolotta[1], C. Catalano[2], M. Midiri[1], R. Lagalla[1], C. Gagliardo[1]; [1]Palermo/IT, [2]Rome/IT
(rob.cannella89@gmail.com)

Purpose: To assess the intraoperative neuroimaging findings in patients treated with transcranial MR-guided focused ultrasound (tcMRgFUS) thalamotomy using 1.5T equipment in comparison with the 48-hours follow-up.
Methods and materials: 50 prospectively-enrolled patients undergoing unilateral tcMRgFUS thalamotomy for either medication-refractory essential tremor (n=39) or Parkinson tremor (n=11) were included. Two radiologists evaluated the presence and size of concentric lesional zones (i.e. zone I, zone II, and zone III) and the presence of oedema extending to the internal capsule on 2D T2-weighted sequences acquired intraoperatively after the last high-energy sonication and at 48-hours follow-up. Sonication parameters including the number of sonications, delivered energy, and treatment temperatures were also recorded. Differences in the lesion pattern and size were assessed using the McNemar test and paired t-test, respectively.
Results: All three concentric zones were visualised intraoperatively in 26 (52%) patients after the last high-energy sonication. Zone I was visible in 29 (58%) cases at intraoperative imaging but was significantly more commonly visualised at 48-hours (96%, p<0.001). The diameter of zone I and II and the thickness of zone III significantly increased at 48-hours (p<0.001). Diameters of zone I and zone II measured intraoperatively demonstrated a significant correlation with thermal maps temperatures (p≤0.006). The maximum average temperature significantly correlated with zone II diameter at 48-hours (p=0.038). A threshold of 56.5° had a sensitivity of 71.4% and a specificity of 60.5% for zone II >10 mm at 48-hours.
Conclusion: Intraoperative imaging may accurately detect typical lesional findings before completing the treatment. These imaging characteristics significantly correlate with sonications parameters and 48-hours follow-up.
Limitations: The different tremor aetiologies, lack of long-term imaging appearance or clinical outcome evaluation, and tcMRgFUS software updates over time.
Ethics committee approval: An IRB-approved study. Informed consent was waived.
Funding: No funding was received for this work.

The correlation between 3T-MRI findings and the clinical outcome in patients submitted to MRgFUS thalamotomy: beyond what we can see

A. Corridore, M. C. de Donato, P. Cerrone, F. Bruno, M. Varrassi, F. Arrigoni, A. Catalucci, P. Sucapane, C. Masciocchi; *L'Aquila/IT*
(antonella.corridore@gmail.com)

Purpose: To evaluate MRI findings on a 3-Tesla-MRI in patients submitted to Vim thalamotomy through MRgFUS in the medium-long-term follow-up.
Methods and materials: We recruited 57 patients affected by essential tremor (25) or tremor due to Parkinson's disease (32) submitted to thalamotomy by MRgFUS in our centre. These patients performed MRI-controls after 1 day, 1 month, 6 months, and 1 year. A complete neurological evaluation was performed at the same time intervals and a correlation between the imaging findings and clinical outcome was performed.
Results: We depicted a progressive reduction of the lesion size (about 8% after 1 month, 30% after 6 months, and 50% after 1 year). SWI sequences were the most reliable in lesion depiction in long-term follow-up: in 68% of cases, no visible lesion was identified in other sequences but was always depicted in SWI sequences. Correlation analysis of lesion size evaluated on follow-up MRI did not show any statistically significant correlation with the clinical outcome (FTM scale) at any interval. Correlation analysis of postprocedural imaging findings with side-effects and complications showed a significant correlation between oedema extension below the AC-PC line and the presence/persistence of ataxia at all follow-up intervals. Lateral lesion extension toward the internal capsule was related to motor complications.
Conclusion: The size of the lesion doesn't show a relationship with the clinical outcome or represent an index of treatment success. The correlation with perilesional oedema can be useful in the clinical evaluation of the medium-long-term side-effects.
Limitations: Further studies with more numerous samples and long-term follow-up are necessary to confirm the stability of the clinical result after a thalamotomy in patients with smaller but potentially more effective lesions.
Ethics committee approval: In accordance with Helsinki declaration.
Funding: No funding was received for this work.

Mapping the cortical connections of the ventral intermediate nucleus with tractography in patients undergoing MRI-guided HIFU thalamotomy

P. Malmierca Ordoqui, A. Paternain Nuin, A. Ezponda Casajus, M. Calvo Imirizaldu, M. C. Rodríguez Oroz, R. Garcia de Eulate, J. Guridi, O. Parras, P. Dominguez Echavarri; *Pamplona/ES (pmalmierca@unav.es)*

Purpose: To evaluate the optimal pre-treatment tractography seed point in the cortex for VIM localisation based on the final HIFU lesion position on post-treatment MRI.
MRI-guided high-intensity focused ultrasound (HIFU) is an effective therapeutic approach for the ablation of the ventral intermediate nucleus (VIM) of the thalamus in drug-refractory tremor. Cortical connections of VIM might differ from person to person. For treatment planning, the best seed points at the cortex are not defined.
Methods and materials: 47 patients with medication-refractory essential tremor or Parkinson disease undergoing VIM ablation contralateral to the patient's hand dominance were recruited. VIM ablations were performed using a HIFU equipment fully compatible with a 3-Tesla MR scanner (Magnetom Skyra, Siemens Healthineers, Erlangen, Germany).
Pre-treatment DTI was co-registered with post-treatment 3D T2WI sequences. The VIM lesion was used as a seed for the DTI-based tractography. Cortical connections were registered and the distance to the mid-sagittal plane was quantified at the juxtacortical white matter on axial T2WI.
Results: HIFU was effective for immediate tremor control. According to cortical connections, patients were allocated into 4 groups: the medial aspect of the primary motor cortex (mM, n=19), intermediate region of the primary motor cortex (between m-M and hand-knob, iM, n=17), hand-knob region of the primary motor cortex (hM, n=2), and supplementary motor area (SMA, n=9). The mean distance from the mid-sagittal plane at these sites was 10.6±1.9 (mM), 17.7±3.2 (iM), 21.9±4.5 (hM), and 9.3±2.2 (SMA) mm.
Conclusion: Seeding of the HIFU-induced VIM lesions on co-registered pre-treatment DTI showed connections predominantly to the primary motor cortex medial to the hand-knob region. This area should be the recommended cortical seeding point for pre-treatment DTI as it will correctly delineate the final treatment location in most patients.
Limitations: The small sample size.

How anxiety influences brain activity: a connectometry study

M. Porcu[1], P. Garofalo[1], F. Destro[1], A. Operamolla[1], A. Caneglias[2], E. Scapin[1], L. Saba[1]; [1]*Monserrato/IT,* [2]*Cagliari/IT (micheleporcu87@gmail.com)*

Purpose: It is known from the literature that anxiety correlates with reduced interhemispheric connectivity on resting-state functional connectivity. The aim of this study is to verify this hypothesis with the connectometry technique.
Methods and materials: We recruited 20 healthy subjects (13 males, 7 female; age 25-80). Each patient on the same day performed the Italian version of the trait scale of the state-trait anxiety inventory (STAI-I) for the assessment of a situation independent general condition of anxiety and then underwent an MR examination on a 3T scanner (Vantage Titan 3T - Canon) with a 32 channel head coil. The MR protocol included a 12 direction DW sequence for the connectometry analysis. The connectometry analysis was performed using a linear regression model to consider the effects of the STAI-I score, choosing three different T-score thresholds (T-threshold) values (1, 2, and 3). Results were considered statistically valid for p-value adjusted for a false discovery rate (p-FDR)<0.05. The network topology analysis measured the influence of the STAI-I score on brain networks.
Results: The connectometry analysis identified several white matter bundles negatively correlated to STAI-I score for T-threshold=3, in particular at the level of corpus callosum (48% of the total amount of tracts identified). Several properties of the network influenced the network topology analysis.
Conclusion: Anxiety is characterised by reduced interhemispheric connectivity measured with the connectometry technique.
Limitations: The small number of patients recruited and the low number of directions used in the DW sequences.
Ethics committee approval: The study was approved by the local ethical committee. Informed consent was obtained.
Funding: No funding was received for this work.

Three-dimensional magnetic resonance fingerprinting at 3.0T: a preliminary clinical evaluation

G. Di Salle, G. Buonincontri, M. Cencini, M. Tosetti, P. Cecchi, G. Migaleddu, M. Cosottini, G. Donatelli*; Pisa/IT*

Purpose: Magnetic resonance imaging has great relevance in CNS pathology, mainly thanks to the multiple, excellent contrasts between tissues. Among its limitations stand long scan times and sensitivity to patients' motion. The present work compared conventional MR sequences with three-dimensional SSFP MR-fingerprinting (MRF) with spiral projection k-space trajectories. Through such technique, acquisition of quantitative data of T1, T2, and proton density allows for the post-hoc synthesis of conventional qualitative contrasts with reduced motion sensitivity. The aim of this study was to compare MRF with conventional MRI in examining normal and pathological brain structures.
Methods and materials: The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated on one phantom and two healthy volunteers. Assessment of absolute and relative contrast between grey and white matter, and qualitative evaluation of both normal encephalic structures and pathological findings representation, was conducted in 10 patients with different diseases, part of a protocol including 250 patients.
Results: SNR and CNR were comparable between MRF and conventional imaging (p>0.05 for all comparisons, except higher SNR of conventional FLAIR sequences in white matter, p=0.016). In MRF, absolute contrast was higher in T1-weighted (p=0.01) but lower in T2-weighted and FLAIR images. Relative contrast was higher in T1-weighted (p=0.0003) and comparable in T2-weighted and FLAIR images. Although not superior to conventional imaging in anatomical detail, MRF alone provided sequences with high diagnostic confidence in 7/10 patients, while the others needed further MR scans to reach conclusive diagnoses.
Conclusion: MRF is a promising tool for MRI in that it may preserve a good diagnostic accuracy while reducing the detriment of a long scan time.
Limitations: The small sample size.
Ethics committee approval: Approved by the local ethics committee.
Funding: Italian Ministry of Health, Health Service of Tuscany (research project GR-2016-02361693).

Magnetic resonance image compilation (MAGiC): utility in epilepsy imaging

R. Vadapalli, A. S. Vadapalli*; Hyderabad/IN (rammohanvsv@gmail.com)*

Purpose: To evaluate the utility of synthetic imaging in refractory epilepsy imaging.
Methods and materials: 40 patients with refractory seizures aged 12-54 years (Mean age 33+6, M:F ratio 3:2) underwent MR exams on a 3T Pioneer scanner (GE Healthcare, Milwaukee) using an epilepsy protocol+MAGIC sequence.
The conventional epilepsy protocol was supplemented with the synthetic MAGIC sequence, which is one scan yielding 6 contrasts: T1, PD T2FLAIR, STIR DIR, PSIR with quantitative T1 and T2 maps (4 minutes).
The images were randomised and independently assessed for diagnostic quality, morphologic legibility, and diagnostic radiologic findings by two independent neuroradiologists compared to the conventional protocol.
The interobserver variability was recorded using Kappa statistics.
Results: The overall diagnostic quality of synthetic MR images was superior to conventional MR imaging for epilepsy on a 5-level Likert scale (P<0.001; mean synthetic-conventional, -0.344±0.312; Δ=0.5; lower limit of the 95% CI, -0.398).
The legibility of synthetic and conventional morphology agreed in >95%, except in the basifrontal cortex and insulo opercular region in T1 and T1 FLAIR (all, >80%). Synthetic T2 FLAIR had more obvious artefacts, including +19.4% of cases with flow artefacts and +12.5% cases with white noise artefacts.
Interobserver variability was in acceptable limits (Cohen's kappa 0.9).
Conclusion: Synthetic MR imaging (MAGIC) with multiple contrasts is an useful adjunct tool in the comprehensive epilepsy protocol for reducing time penalties.
Limitations: iSyntheic image datasets are still 2D datasets. 3D synthetic imaging data is emerging and high-resolution 3D FLAIR T1 and T2 are still needed for a comprehensive evaluation.
Ethics committee approval: Waiver of informed consent by ERB.
Funding: No funding was received for this work.

RPS 1411c-7 11:51

Synthetic diffusion-weighted imaging (MAGIC DWI) in stroke imaging: a study of 52 cases

R. Vadapalli[1], A. S. Vadapalli[2]; [1]*Hyderabad/IN,* [2]*London/UK (rammohanvsv@gmail.com)*

Purpose: To evaluate the role of multi b-value synthetic diffusion-weighted imaging in the evaluation of stroke.
Methods and materials: 52 patients who presented with symptoms suggestive of stroke with ages of 39-81 years (mean age 49.5+/-10 years; M: F ratio 2:3) were evaluated by a dedicated stroke protocol and supplemented by an additional 2-minute synthetic magic DWI multi b-value protocol after a waiver from IRB.
The parameters of synthetic DWI sequence are as follows: multi b-value DWI acquisition with b-values of 0-1,000 and synthesis of b-values of 1,500 and 2,000, with the maximum b-value not exceeding 2,500.
The sensitivity of the detection of infarcts on conventional DWI was compared to MAGIC DWI.
Results: Of 52 patients, 31 had multiple acute lacunar infarcts in the MCA territory and MCA and PCA watershed zones, 21 in the infratentorial region including the brain stem and cerebellum, and 6 with a sensitivity of 92% and specificity of 97% with conventional DWI.
Using the MAGIC DWI with the synthesis of multiple b-values between 1,000 to 2,500, the sensitivity and specificity significantly improved to 97% and 99%, with an NPV of 99%.
Conclusion: Multi B-value ultra-fast synthetic MAGIC DWI, which is a synthetic diffusion technique, is a powerful adjunct tool to the conventional stroke protocol offering the user a retrospective synthetic slider to generate multi b-value data from 100-2,500, increasing the sensitivity of stroke detection with no time or SNR penalties.
Limitations: B-values above 2,500 are not feasible. The ADC value can be calculated until 1,000.
Ethics committee approval: Ethics committee approval and informed consent obtained.
Funding: No funding was received for this work.

3D high-resolution myelin imaging using synthetic MRI

M. J. B. Warntjes, P. Johansson, P. Lundberg, A. Tisell*; Linköping/SE (marcel.warntjes@cmiv.liu.se)*

Purpose: Quantitative assessment of myelination is an important clinical biomarker in treatment and follow-up. Myelin can be measured using synthetic MRI; the measurement of the R1 and R2 relaxation and proton density PD, in conjunction with a myelin model, can provide myelin partial volume maps for the entire brain. Recently, a 3D acquisition method was developed for high-resolution, isotropic synthetic MRI. The purpose of this work was to compare myelin detection using 2D and 3D.
Methods and materials: The 3D QALAS sequence is a segmented spoiled gradient-echo sequence with 5 parallel acquisitions, interleaved with a T2 preparation and inversion pulse. The 2D MDME sequence (MAGiC) is a saturation recovery multi-slice TSE sequence with multi-echo read-out. A group of 12 volunteers was acquired two times with 3D QALAS and two times with MDME, both at 1.5T and 3T.
Results: The mean myelin volume for the entire group was 183 mL and the mean brain volume was 1,300 mL (14.1%). A high correlation was found between volumes determined by QALAS and MDME. The Pearson correlation coefficient was 0.94 and the mean difference was 0±13 mL. The difference between measurement 1 and 2 was -2±10 mL at 1.5T and 1±13 mL at 3T for QALAS, whereas it was 0±4 mL at 1.5T and -3±4 mL at 3T for MDME.
Conclusion: Myelin measurements using 3D QALAS provides very similar values of myelin and brain volumes in comparison to 2D MDME. The advantage of 3D QALAS is the ability to view the data in all orientations.
Limitations: A small number of subjects, all of which were healthy.
Ethics committee approval: The study was approved by the local ethical board. All participants provided written informed consent.
Funding: No funding was received for this work.

In vivo description of the cerebral microvascular structures of a preterm newborn: the feasibility of superb microvascular imaging (SMI)

A. Barletta[1], P. A. Bonaffini[1], M. Balbi[1], A. Surace[1], A. Caroli[2], S. Gerevini[1], S. Sironi[1]*; [1]Bergamo/IT, [2]Ranica/IT (ninnibarletta@gmail.com)*

Purpose: To explore the potential of superb microvascular imaging (SMI) technology in visualising brain microvessels in preterm neonates of different gestational ages (GA).
Methods and materials: A retrospective, observational, single-centre study including 15 newborns (8 females) was conducted. Preterm patients were equally divided into GA groups according to the WHO sub-categories: extremely (GA< 28 weeks, EP), very (28-31 weeks and 6 days, VP), and moderate to late preterm (32-37 weeks, MLP). All patients underwent transcranial ultrasound (US) using a Toshiba Aplio500 scanner (Canon Medical Systems Corporation) and a linear 14 MHz transducer. Exams were performed during the first day of life via the anterior fontanel including superficial and deep scans (each on coronal and parasagittal planes). Based on their SMI morphology and location, microvessels were classified as extrastriatal (subdivided into cortical and medullary), striatal, or thalamic. Two examiners independently classified the vessels as visible (echogenic linear structures) or invisible. To assess the association between vessel visibility and GA, a binomial logistic regression analysis (separate for each microvessel group) was performed, taking visibility as a dependent variable and both examiners and GA as predictor variables.
Results: A statistically significant difference among GA groups was found in sex ($p=0.030$), GA by definition ($p=0.002$), weight at birth ($p=0.007$), and the Apgar score within 1 minute ($p=0.024$). GA significantly contributed to the visibility of superficial vessels ($p<0.05$ for both cortical and medullary ones) but not striatal and thalamic vessels.
Conclusion: SMI-US is a feasible tool for visualising and assessing intraparenchymal brain microvasculature in pre-term neonates. The morphology and distribution of the brain microvessels seen in the current study are consistent with those described in previous anatomical and radiological research.
Limitations: The retrospective analysis of images.
Ethics committee approval: Written informed consent was obtained.
Funding: No funding was received for this work.

The validity of SyMRI in the assessment of the neonatal brain

V. Schmidbauer, M. C. Diogo, S. A. Jengojan, K. Goeral, A. Berger, D. Prayer, G. Kasprian*; Vienna/AT (schmidbauervictor@gmail.com)*

Purpose: To assess the diagnostic accuracy of T1- and T2-weighted contrasts generated by the MR data post-processing software SyMRI for neonatal brain imaging.
Methods and materials: A total of 32 neonates were included in this retrospective study. 4 independent rating neuroradiologists assessed the neonatal brain on the basis of conventional and SyMRI generated T1- and T2-weighted contrasts. The sensitivity and specificity of both methods were calculated and compared with each other.
Results: Compared to conventionally acquired T1- and T2-weighted images, SyMRI-generated contrasts showed a lower sensitivity but a higher specificity [SyMRI: sensitivity: 0.88, confidence interval (CI): 0.72-0.95; specificity: 1, CI: 0.89-1/conventional MRI: sensitivity: 0.94, CI: 0.80-0.98; specificity: 0.94, CI: 0.80-0.98].
Conclusion: T1- and T2-weighted images, generated by SyMRI showed a comparable diagnostic accuracy to conventionally acquired contrasts. In addition to semi-quantitative imaging data, SyMRI provides diagnostic images and leads to more efficient use of available imaging time in neonatal brain MRI.
Limitations: The small sample size.
Ethics committee approval: The protocol of this study was approved by the local ethics commission and performed in accordance with the declaration of Helsinki.
Funding: No funding was received for this work.

Sodium MRI in mild traumatic brain injury

H. Grover, Y. Qian, F. Boada, K. Lakshman, S. Flanagan, Y. Lui*; New York/US (hemalgrover@gmail.com)*

Purpose: Metabolic derangements are known to occur after traumatic brain injury (TBI). Animal models point to initial Na^+ influx causing membrane depolarisation. White matter, particularly the corpus callosum (CC), is susceptible to damage. The purpose of this study is to compare the distribution of the total sodium concentration (TSC) in the CC between patients of mild TBI (mTBI) and controls using sodium MRI.
Methods and materials: 11 patients (6 M, 5 F; 20-52 years) with a history of mTBI and 10 healthy controls were studied. Sodium MRI scans were performed on a Siemens Prisma3T scanner using a custom 8-channel dual-tuned (1H-23Na) Tx/Rx head coil. Twisted projection imaging was used (FOV=220 mm, matrix size=64, TE/TR=0.3/100 ms, FA=90, and TA=10.3 min).
Sodium MR images were visually inspected in conjunction with proton MPRAGE. TSC was measured in genu, body, and splenium with 5 mm regions of interest (ROI). To assess for reproducibility, 5 measurements were independently taken within each area. A comparison was made between cohorts with a significance level of 0.05. To assess the distribution of TSC along the CC in the anterior-posterior dimension, the TSC genu/splenium ratio was calculated.
Results: TSC was higher in the genu (51.59 vs 45.6 mmol, $p=0.049$) and lower in the splenium (50.80 vs 41.88 mmol, $p=0.01$) in mTBI patients compared to controls. The genu/splenium ratio was also higher in patients (1.2 vs 0.9, $p=0.001$). On visual inspection, mTBI subjects demonstrated a reversal of the normal TSC anterior-posterior gradient in the CC compared with controls.
Conclusion: TSC distribution in the CC is altered after mTBI. Since changes in extracellular Na^+ concentration are transient after brain injury, detected alterations in TSC are believed to be attributable to changes in the intracellular Na^+ concentration. Our work supports the notion of ongoing Na^+ channelopathy after injury affecting callosal white matter such as perturbed expression of sodium channels.
Limitations: The small sample size.
Ethics committee approval: Institutional IRB approved study.

RPS 1411c-12 12:21

What have we learnt from delving deeper? Is MR-guided focused ultrasound targeting the zona incerta with the ventral intermedius nucleus an effective treatment for essential tremor long-term?

A. J. Jameel[1], W. M. W. Gedroyc[1], D. Nandi[1], B. Jones[1], O. Kirmi[2], S. Malloy[1], Y. F. Tai[1], P. Bain[1], G. Charlesworth[1]; [1]*London/UK,* [2]*Oxford/UK*
(ayesha.jameel@nhs.net)

Purpose: Magnetic resonance-guided focused ultrasound (MRgFUS) is a non-invasive treatment for essential tremor (ET) that allows targeted thermal ablation of brain tissue. Previous studies demonstrate targeting the thalamic ventral intermedius nucleus (Vim) as an effective treatment in ET. This paper describes the world's first trial using MRgFUS to target both the Vim and the inferior zona incerta (ZI).
Methods and materials: This prospective study enrolled 13 patients with medication refractory ET for a unilateral MRgFUS procedure. Tremor severity and functional impairment were assessed at baseline and regular intervals post-treatment for 24 months, using the clinical rating scale for tremor (CRST).
BFS spirals were also collated intraoperatively, immediately pre-procedure and after targeting the Vim and ZI. All spirals were scored by 3 blinded neurologists. The percentage improvement in the spiral scores after Vim and ZI ablation were compared and analysed.
Results: In all patients, there was successful thermal ablation of the target tissue at both Vim and ZI with improvement in all parameters stable over 24 months. The CRST tremor score improved by 73.5% (treated arm) and 24% (non-treated arm).
The intraoperative BFS scores demonstrated the additional benefit of targeting the ZI was 21.8%; improvement after Vim lesioning was 27.9%, but after both Vim and ZI lesioning was 49.7%.
One patient (7.69%) experienced a significant adverse event; post-treatment unilateral hemi-chorea persistent at 2 years.
Conclusion: Our study provides further evidence that MRgFUS is an effective curative treatment for ET and demonstrates the additional benefit of targeting the thalamic Vim with the inferior ZI. Improvement in the tremor scores of the non-treated arm shows the positive bilateral effects of targeting the ZI.
Limitations: The limited sample size.

CT texture analysis of gastrointestinal stromal tumours (GIST)

E. Tabone[1], G. Cappello[2], V. Giannini[2], A. Defeudis[2], R. Cannella[3], T. V. Bartolotta[3], D. Regge[2]; [1]*Turin/IT,* [2]*Candiolo/IT,* [3]*Palermo/IT*

Purpose: To evaluate the association between radiomic biomarkers extracted from baseline CT imaging and the mitotic count, tumour mutational profile, and prognostic Miettinen classification.
Methods and materials: This retrospective multicentre observational study included 63 histologically proven GISTs. Each lesion was manually segmented and 37 texture features were extracted both on a single slice and on the entire tumour volume. The reference standards were pathological findings and the Miettinen classification. Patients were dichotomised with the mitotic count (≤5/50HPF vs >5/50HPF), mutational status (c-KIT mutation vs PDGFRα and Wild-Type), and patient prognosis (good prognosis class: none, very low, and low risk vs poor prognosis class: intermediate and high risk). Univariate analyses using the Mann-Whitney test and multivariate analysis were performed and a stepwise logistic regression model to predict the patients' prognosis was developed using 70% of patients as the training set and the remaining 30% as the test set.
Results: 8 3D-features discriminated lesions with a low or high mitotic-count (best AUC 0.81, best sensitivity 86%, and best specificity 93%). 6 3D-parameters detected GISTs based on the mutational group (best AUC 0.77, best sensitivity 75%, and best specificity 79%) and 3 parameters correlated with the risk class (best AUC 0.76, best sensitivity 72%, and best specificity 85%). In the differentiation between GIST at a lower or higher risk of recurrence, the regression model used 6 different features and obtained AUC 0.78, sensitivity 65%, specificity 79%, VPN 71%, and VPP 73% on the training set, and AUC 0.83, sensitivity 88%, and specificity 75% on the test set.
Conclusion: Our results show a good correlation between radiomics features, disease aggressiveness, mutational profile, and the risk of recurrence. Results are promising but validation on external datasets will be necessary to confirm the role as an imaging biomarker.

The prognostic role of diffusion kurtosis imaging for advanced gastric cancer after neoadjuvant chemotherapy

J. Fu, L. Tang, Q. Shi, Z. Li, Y.-S. Sun, J. Ji; *Beijing/CN*
(18410259295@163.com)

Purpose: To investigate whether DKI parameters are associated with overall survival (OS) in patienta with advanced gastric cancer after neoadjuvant chemotherapy.
Methods and materials: From 2014-2016, 46 consecutive patients with a biopsy-proven gastric cancer who underwent pre-neoadjuvant chemotherapy MRI with DKI (b=0, 200, 500, 800, 1,000, 1,500, and 2,000s/mm^2) were enrolled in this retrospective study. The region of interest was manually drawn on the specific slice showing the largest area of the tumour. Three parameters of DKI were calculated automatically: apparent diffusion coefficient (ADC, b=800s/mm^2), kurtosis (K), and diffusivity (D) value. Cox proportional hazards analyses were performed to determine the relationship between DKI parameters, neoadjuvant pathologic T-stages, tumour location, histologic subtype, and OS.
Results: The median follow-up was 37.7 months and 11 patients had died at a median time of 16.6 months. There was no significant difference in pre-treatment DKI parameters between the histologic subtypes. The ADC and K values were associated with a negative prognosis ($p=0.048$, $p<0.001$). Cox analysis showed that the K value ([HR], 1.011; 95% [CI]: 1.005, 1.018; $p<0.001$) was the representative predictor of OS. The optimum threshold point was 0.618.
Conclusion: DKI parameters can potentially provide prognostic information complementary to ADC for gastric cancer patients after neoadjuvant chemotherapy.
Limitations: The relatively small population in our study might result in bias in the results. We only explored the correlation between pre-neoadjuvant chemotherapy (pre-NACT) DKI parameters and overall survival, not all prognostic factors such as DKI parameters of post-NACT or PFS.
Ethics committee approval: This study was approved by our local institute review board.
Funding: No funding was received for this work.

A radiomics approach to characterise the deficient DNA mismatch repair system and predict survival in colorectal cancer patients

Y. Y. Huang, Y. Li, Z. Liu; *Guangzhou/CN (yikiann@126.com)*

Purpose: To develop and validate a radiomic signature to characterise the deficient mismatch repair (MMR) system and investigate its prognostic value for survival prediction in colorectal cancer patients (CRC).
Methods and materials: The training cohort included 170 CRC from January 2008-December 2010. The independent validation cohort contained 91 patients from January 2011-December 2013. 92 features were extracted from tumours on venous-phase CT. We developed a radiomic signature to characterise MMR status (deficient MMR [dMMR] vs proficient MMR [pMMR]) with a Lasso regression model with discrimination and calibration performance assessed and validated, followed by a prediction performance of the radiomic signature for the overall survival (OS) assessed and validated.
Results: The radiomic signature, consisting of 3 features, was associated with MMR status (P<0.001 for both cohorts). The radiomic signature showed good discrimination (C-index: 0.815 [95% CI :0.693, 0.931] in the training cohort; 0.815 [0.712, 0.914] in the validation cohort) and good calibration. This MMR-related radiomic signature was found significantly associated with OS (training cohort: p=0.008, validation cohort: p=0.028) and was a significant predictor for OS when validated (C-index=0.66; 95% CI: 0.55–0.76; p<0.001). OS was significantly improved in the high-radiomic-score group (HR: 2.506, 95% CI: 1.071–5.863; p:0.034).
Conclusion: Our study presents a radiomic signature to characterise a deficient MMR system, which was shown to be predictive of OS in CRC. This study, through applying radiomics to correlate molecular subtypes with OS, suggests that radiomics might offer a non-invasive way to predict survival by identifying imaging features that could reflect underlying molecular drivers. This study might shed light on patient stratification for 'omics'-guided therapies and envision the future of precision medicine.
Limitations: The retrospective nature of data collection and the lack of external validation.
Ethics committee approval: Ethical approval by the institutional review board was obtained for this retrospective analysis with informed consent waived.
Funding: The National Natural Scientific Foundation of China (No.81771912 and 81701782).

The utility of radiomics at baseline rectal MRI to predict the clinical complete response of rectal cancer after chemoradiation therapy
E. J. Ortiz[1], F. Tixier[1], J. S. Golia Pernicka[2], V. Paroder[1], D. Bates[1], N. Horvat[1], M. J. Gollub[1], H. Veeraraghavan[1], I. Petkovska[1]; [1]*New York, NY/US,* [2]*Bridgeport, CT/US (ejoh85@gmail.com)*

Purpose: To investigate the significance of T2-weighted-based radiomic data extracted from baseline rectal MRI combined with qualitatively assessed imaging features in predicting the clinical complete response after neoadjuvant CRT for rectal cancer.
Methods and materials: A retrospective study of patients with locally advanced rectal cancer who underwent rectal MRI before neoadjuvant CRT from October 2011–January 2015 followed by surgery was conducted. The reference standard for the pathologic complete response was the surgical histopathologic specimen after CRT. Qualitatively assessed imaging features were extracted from our institutional standardised radiology report. In radiomics analysis, one radiologist manually segmented the primary tumour on T2-weighted images for 102 patients to be used as the training set; two different radiologists independently segmented 66/102 patients to be used as the validation set. Using CERR software, 108 radiomics features were extracted. The Wilcoxon test was used to identify scanner-independent features. Subsequently, a least absolute shrinkage operator analysis was used to extract a radiomics score. A support vector machine model combining the radiomics score and qualitatively assessed clinical descriptors was compared against both clinical and radiomics-only models using the deLong test.
Results: 102 patients were included. The radiomics score produced an AUC of 0.75. Comparable results using the validation set were AUC=0.69 and 0.71 for each radiologist, respectively. The SVM model using the qualitative features had an accuracy of 67% (sensitivity 42%, specificity 72%); when adding the radiomics score, the accuracy increased to 74% (sensitivity 58%, specificity 77%).
Conclusion: The prediction of the clinical response to stratify patients before neoadjuvant therapy may be obtained by combining a radiomics-based score and qualitatively assessed features from pre-treatment rectal MRI.
Limitations: The manual segmentation, radiomics analyses based on T2-weighed images only, and imbalanced dataset.
Ethics committee approval: Institutional IRB approval.
Funding: Funding in part through the NIH/NCI Cancer Center Support Grant P30CA008748 and the Colorectal Cancer Research Center CC50367 at MSKCC.

RPS 1516-5 14:24
Data mining for the evaluation of response to neoadjuvant chemoradiotherapy in locally advanced rectal cancer using a decision tree algorithm
F. Landolfi[1], M. Rengo[1], S. Badia[2], S. Picchia[2], E. Iannicelli[1], A. Laghi[1]; [1]*Rome/IT,* [2]*Latina/IT (federica.landolfi@uniroma1.it)*

Purpose: To develop and validate a decision tree model based on high-resolution T2-weighted (T2w) magnetic resonance (MR) images features, to discriminate between complete responder (CR) and partial/non-responder (P/NR) patients with locally advanced rectal cancer (LARC) after neoadjuvant chemoradiotherapy (CRT).
Methods and materials: A population of 65 patients (training cohort; 23 CR and 42 P/NR) was selectedto train a J48 classifier algorithm in identifying CR and P/NR patients, analysing images acquired on a 3 Tesla scanner. The developed model was validated on a population of 30 patients (validation cohort; 9 CR and 21 P/NR) who underwent MR on a 1.5 Tesla scanner.4 features, manually measured by 2 expert radiologists on pre and post CRT T2wimages were used to build the model: the tumour volume before and after therapy, MR tumour regression grade (MR-TRG) assessed according to Mandard score, volume reduction ratio (VRR), and T2 signal reduction ratio (DSI). All patients underwent surgical resection and histopathology was employed as the standard reference.
Results: The model correctly classified 26 (86.67%) patients with a mean absolute error of0.16%. Only 4 patients (13.33%) were misclassified: 3 CR classified as P/NR and1 P/NR classified as CR. The sensitivity for the identification of CR was 0.67, thespecificity 0.95.
Conclusion: The model, based only on manually-extracted features from T2w images, provided a high accuracy (86.67%) in the evaluation of CRT response, correctly classifying 95% of P/NR and 67% of CR. In the emerging scenario of a "wait and see" policy, these results could prove to be a very useful tool in the identification of P/NR patients, thus avoiding a delay of surgery in patients with a residual tumour and a surgical overtreatment in patients with complete response to CRT.
Limitations: A retrospective study with a small population sample.
Ethics committee approval: n/a
Funding: No funding was received for this work.

The impact of a structured report on the quality of preoperative CT staging of pancreatic ductal adenocarcinoma
M. Di Marco, F. Vernuccio, R. Cannella, S. Pellegrino, F. Allegra, D. G. Castiglione, G. Salvaggio, M. Midiri, G. Brancatelli; *Palermo/IT (davidegiuseppecastiglione@gmail.com)*

Purpose: To test whether a standardised structured radiology report improves the quality of preoperative CT staging of pancreatic ductal adenocarcinoma (PDA) compared to conventional free-text reports.
Methods and materials: In this retrospective, single-centre study, we included 27 patients (mean age, 64±11.1 years) with pathologically proven PDA operated on between 2015-2018 and imaged with pancreatic CT. 4 readers independently reported CT scans with both free-text and a structured report. The differences in reported morphologic and vascular features were assessed through a McNemar Test. The intra-reader and inter-reader agreements were calculated.
Results: 216 (108 conventional and 108 structured) reports were analysed. Encasement of the left gastric artery, gastroduodenal artery, and splenic artery was described in up to 14.8% using free-text reports and up to 29.6% using a structured report, resulting in low intra-reader agreement (k=0.033-0.216). Inter-reader agreement improved with a structured report compared to free-text reports for the left gastric artery (ICC=0.844 vs ICC=0.493, respectively), gastroduodenal artery (ICC=0.730 vs ICC=0.449, respectively), portal vein (ICC=0.847 vs ICC=0.638, respectively), portal confluence (ICC=0.848 vs

ICC=0.422, respectively), superior mesenteric vein (ICC=0.765 vs ICC=0.695, respectively), and the splenic vein (ICC=0.921 vs ICC=0.841, respectively).
Conclusion: The use of structured reports improves the quality of preoperative CT staging of pancreatic adenocarcinoma by significantly reducing the number of missed morphological and vascular features of PDA. Moreover, structured reporting results in a significant improvement of inter-reader agreement compared to free-text reports.
Limitations: The limited number of patients, retrospective nature, potential to miss unexpected findings not included in the template, potential testing or learning effect, and lack of time constraints for reporting.
Ethics committee approval: IRB approved. Waiver of informed consent obtained.
Funding: No funding was received for this work.

RPS 1516-8 14:42
Low-energy virtual monoenergetic images from DECT can improve the accuracy of CT perfusion calculations
S. Skornitzke, H.-U. Kauczor, W. Stiller*; Heidelberg/DE*
(Stephan.Skornitzke@med.uni-heidelberg.de)

Purpose: Virtual monoenergetic images (VMI) from dual-energy computed tomography (DECT) can improve image quality in contrast-enhanced abdominal CT imaging. A translation to CT perfusion could increase measurement accuracy by improving the delineation of changes in contrast agent concentrations.
Methods and materials: Dual-source DECT scans were acquired in 17 patients with pancreatic carcinomas with a DECT perfusion protocol consisting of 34 acquisitions at 80kV$_p$/Sn140kV$_p$ over 51 seconds. VMIs were calculated for energy levels between 40keV and 150keV in 5keV steps (Monoenergetic+, Siemens Healthineers). Perfusion maps of blood flow were calculated using the maximum-slope model for VMIs and polyenergetic 80kV$_p$ images. Perfusion maps were quantitatively evaluated in terms of blood flow in healthy tissue and the carcinoma, the contrast between tissue types, noise, and contrast-to-noise ratio (CNR), comparing VMIs to 80kV$_p$ images.
Results: The measured blood flow increased with energy level from 114±37ml/100ml/min (healthy tissue) and 46±25ml/100ml/min (carcinoma) for 40keV to 129±59ml/100ml/min (healthy tissue) and 76±50ml/100ml/min (carcinoma) for 150keV, compared to 114±37ml/100ml/min (healthy tissue) and 47±27ml/100ml/min (carcinoma) for 80kV$_p$ images. The differences between tissue types were statistically significant for all VMIs and 80kV$_p$ images ($p<0.05$). The measured blood flow was not significantly different between VMIs and 80kV$_p$ images for energies below 110keV. Noise in perfusion maps was reduced for low-energy VMIs (40keV:19ml/100ml/min; 80kV$_p$:23ml/100ml/min) and CNR was higher (40keV:3.7±1.9; 80kV$_p$:3.2±1.6) compared to 80kV$_p$ images. The differences in noise and CNR were statistically significant for all energy levels except those between 60keV and 75keV.
Conclusion: CT perfusion maps calculated from low-energy VMIs show improved quantitative image quality compared to conventional polyenergetic 80kV$_p$ images.
Limitations: Further evaluation of diagnostic image quality and patient radiation exposure seems necessary.
Ethics committee approval: Institutional review board approval and written informed consent were obtained.
Funding: No funding was received for this work.

The apparent diffusion coefficient (ADC) allows early prediction of response after prophylactic DC vaccination for pancreatic ductal adenocarcinoma (PDAC) prevention
A. J. Shangguan[1], M. Figini[2], L. Pan[3], J. Yang[1], A. Eresen[1], Y. Velichko[1], V. Yaghmai[1], Z. Zhang[1]; *[1]Chicago, IL/US, [2]London/UK, [3]Suzhou/CN*
(junjie.shangguan@northwestern.edu)

Purpose: We evaluated ADC as an imaging biomarker for the prediction of response to prophylactic DC vaccination in a Panc02 mouse model of pancreatic cancer,
Methods and materials: 20 mice were randomly assigned to treatment or control groups. The animals underwent 3 intraperitoneal injections of DC vaccines, mature DCs, Panc02 lysates, or no treatment, followed by tumour induction via Panc02 cell injection into the pancreas and weekly MRI scans. ADC was calculated from DW-MRI using MatLab. ΔADC is the ADC difference between 1 and 3w after tumour induction. Tumour tissue was collected for histology. Statistical analysis was performed on GraphPad Prism. The receiver operating curve (ROC) was generated.
Results: The ΔADC of the vaccines group was higher than the control groups and correlated with a diminished tumour volume, survival, and % interstitial collagen on histology. Prophylactic DC-vaccination also induced an anti-tumour immune response in vivo, a decreased tumour volume, and prolonged survival. Survival >49d was considered positive events for ROC. Distance analysis and Youden indexing both showed that optimal cut-off values were $-8.52\text{x}10^{-5}$ and $-9.24\text{x}10^{-5}$, with specificities of 0.9 and 0.7, and an odds ratio of 2.33.
Conclusion: ΔADC can predict the response to prophylactic DC vaccination in a Panc02 mouse model of pancreatic cancer.
Limitations: Our study only tracked up tumour growth for 3 weeks and did not track serum pro-inflammatory cytokines in mice. However, 3-time points are a sufficient number of time points for tracking tumour growth in MRI studies. We also demonstrated in vivo anti-tumor cell-mediated cytotoxicity using LDH assay.
Ethics committee approval: All animal protocols were approved by the institutional animal care and use committee.
Funding: The National Institutes of Health of USA, Radiology Society of North America, Fischel Fellowship, and Eisenberg Award.

The value in preoperative detection of pancreatic neuroendocrine tumours with spectral images derived from dual-layer spectral detector CT
Y. Yang, R. Li, J. Xu, Q. Han, X. Chen, F. Yan*; Shanghai/CN*
(yyz01a15@rjh.com.cn)

Purpose: To investigate the added value of spectral images derived from dual-layer spectral detector CTs (DLCT) for pancreatic neuroendocrine tumour (pNET) preoperative detection in comparison to 120-kVp conventional polyenergetic images (PI).
Methods and materials: 23 patients were pathologically confirmed of pNET after operations were enrolled. PI, iodine density map, and virtual monoenergetic images (VMI) were reconstructed. One resident and one senior radiologist independently interpreted the images to lesion localisation using PI and subsequently combined PI and spectral images. The CT value and iodine density of the lesion and pancreatic parenchyma were collected. CNR were calculated and compared between VMIs and PI. Lesion detection accuracy was recorded and compared with and without spectral images.
Results: There were 26 confirmed lesions among 23 patients. The detected tumours increased from 20 to 24 with additional spectral information compared to only with PI for the resident radiologist, and from 23 to 25 for the senior radiologist. The sensitivity of the preoperative diagnosis of pNET increased from 76.9% to 92.3%, and from 88.5% to 96.2%, respectively. The CT value of the lesion with VMI$_{40keV}$ was significantly higher than with PI; 179.3±35.3 HU vs 504.1±129.3 HU in the artery phase and 148.3±25.9 HU vs 401.8±87.4 HU in the portal phase. The CNR of the lesion with VMI$_{40keV}$ was higher than with PI; 3.4±1.8 HU vs 12.8±6.6 in the artery phase and 2.7±1.6 HU vs 10.2±5.8 in the portal phase (all $p<0.001$).
Conclusion: Preoperative diagnostic performance for pNET can be significantly improved with spectral images derived from DLCT. VMI$_{40keV}$ provided the best conspicuity and highest CNR of the lesion.
Limitations: The number of patients was relatively small.
Ethics committee approval: Written informed consent obtained.
Funding: No funding was received for this work.

RPS 1516-11 15:00

Iodine concentration and tissue density in dual-energy contrast-enhanced CT as a potential quantitative parameter in early detection of local pancreatic cancer recurrence

R. M. Mathy, F. Fritz, W. Stiller, H.-U. Kauczor, S. Skornitzke*; Heidelberg/DE*

Purpose: Early diagnosis of local pancreatic cancer recurrence remains challenging. We quantitatively evaluated the diagnostic potential of dual-energy (DE) contrast-enhanced CT for distinguishing recurrent carcinoma from the unspecific postoperative soft-tissue formation (PSF).
Methods and materials: After potentially curative pancreatic carcinoma resection, 36 consecutive patients with PSF were examined with DECT, acquiring 34 images ($80kV_p/140kV_p$) every 1.5s starting 13s after the bolus injection (80ml contrast agent, 370mg/ml, flow rate 5ml/s). Corresponding time points of arterial, pancreatic, and early venous phase (delay 10s, 19s, and 30s) were calculated from bolus trigger times in prior conventional CTs. Iodine and $120kV_p$-equivalent (M0.5) images were calculated. Regions of interest were placed in each soft-tissue formation. The diagnosis of local recurrence was confirmed by regular follow-up or by histological study.
Results: The final diagnosis was a local recurrence in 23 patients and unspecific PSF in 13 patients. The early venous average iodine concentration in recurrent carcinomas was significantly higher than in unspecific PSF (1.4mg/ml vs 0.9mg/ml, p=0.02). Arterial and pancreatic phase iodine concentrations in recurrent carcinomas were higher than in unspecific PSF, but not significant (1.2mg/ml vs 1.0mg/ml, p=0.24; 1.3mg/ml vs. 1.2mg/ml, p=0.48, respectively). Early venous density of recurrent carcinoma in $120kV_p$-equivalent images was significantly higher (70HU vs 48HU, p=0.008). The ROC-curve analysis for early venous iodine concentrations (AUC=0.76) suggests cut-off values >=1.5mg/ml for local recurrence (specificity 0.92, sensitivity 0.57) and <=0.5mg/ml for unspecific PSF (specificity 0.96, sensitivity 0.45).
Conclusion: In difficult cases, measuring iodine concentrations or density in PSF in (early) venous phase DECT can be a valuable additional parameter for differentiating local recurrence from unspecific PSF.
Limitations: The initial purpose of this study was evaluating CT-perfusion, so the protocols were not optimised for evaluating DECT-data.
Ethics committee approval: Institutional review board approval and written informed consent were obtained.
Funding: Supported by BMBF-grant 031L0163.

Portal radiomics in pancreatic head cancer: the relationship to the superior mesenteric vein resection margin

Y. Bian, X. Fang, L. Wang, J. Lu, G. Jin, H. Zhang*; Shanghai/CN (bianyun2012@foxmail.com)*

Purpose: To accurately identify the relationship between the portal radiomics score (rad-score) and the pathologic superior mesenteric vein (SMV) resection margin in patients with cancer in the head of the pancreas.
Methods and materials: 181 patients with pathologically confirmed cancer in the head of the pancreas who underwent multislice computed tomography within one month of resection from January 2016-December 2018 were retrospectively investigated. For each patient, 1,029 radiomics features of the portal phase were extracted, which were reduced using the least absolute shrinkage and selection operator (LASSO) logistic regression algorithm. Multivariate logistic regression models were used to analyse the association between the portal rad-score and SMV resection margin.
Results: Patients with negative (R0) and positive (R1) margins accounted for 70.17% (127) and 29.83% (54) of the cohort, respectively. The rad-score, which is based on 11 selected portal phase features, was significantly associated with the SMV resection margin status (P<0.05). Multivariate analyses confirmed a significant and independent association between the portal rad-score and SMV resection margin (P<0.0001); a higher portal rad-score was associated with R1 resection (P for trend <0.0001).
Conclusion: The portal rad-score is independently and positively associated with the risk of the SMV R1 resection in pancreatic head cancer.
Limitations: Retrospective in nature, the results were established based on data obtained from a single centre, and the available samples were limited.
Ethics committee approval: This retrospective single-centre cross-sectional study was reviewed and approved by the Biomedical Research Ethics Committee of Changhai Hospital.

A radiomics approach to pancreatic adenocarcinoma characterisation compared to the routine evaluation of CE-MDCT tissue attenuation features

V. Tikhonova, I. Gruzdev, E. V. Kondratyev, G. Karmazanovsky*; Moscow/RU (vdovenkobc28@mail.ru)*

Purpose: Attenuation characteristics of the pancreatic ductal adenocarcinoma (PDAC) and contrast material uptake vary depending on the histological grade and pancreatic parenchyma condition. The purpose of this study was to compare dynamic contrast enhancement (DCE) and radiomics features in predicting pancreatic adenocarcinoma grades. The data obtained from an analysis of the radiomics of pancreatic cancer can subsequently be used to predict the prognosis of patients with PDAC and for the inclusion of big data analysis in the diagnosis process.
Methods and materials: 62 consecutive patients with histologically-confirmed PDAC who underwent CE-MDCT were enrolled in the study. We compared the mean lesion attenuation and relative tumour enhancement ratio (RTE) of different types of PA and radiomics features using arterial, venous, and delayed-phase MDCT scans.
Results: Tumour attenuation parameters showed significant association with the PDAC grade, especially when calculated using both venous and delayed-phase images. RTE_{del} showed a significant difference between low and high-grade PDAC (-0.17±0.3 vs -0.06±0.09, p<0.005). RTEart showed a significant difference between intermediate and high-grade PDAC (-0.52±0.23 vs -0.67±0.19, p<0.05). We identified different radiomics features that best correlated with the PDAC grade (MPP, kurtosis, SSF etc). The diagnostic performance of joint CE-MDCT features with radiomics signature increased compared with CE_MDCT features alone (sensitivity 97.3 vs 91.3%, specificity 84.1 vs 80%).
Conclusion: The analysis of radiomics features and DCE features is useful for PDAC grade prediction.
Limitations: The study was single-centred with standardised CE-MDCT protocols. We plan to test the robustness of texture analysis in future studies.

Pancreatic solid pseudopapillary neoplasm: CT imaging appearance correlation with invasive behaviours

W. Mingliang, Z. Mengsu*; Shanghai/CN (wang.mingliang@zs-hospital.sh.cn)*

Purpose: To investigate the CT imaging appearance of pancreatic solid pseudopapillary neoplasm (pSPN) in predicting pathological invasive behaviours.
Methods and materials: The clinical data and CT data of 103 patients with solid pseudopapillary neoplasm confirmed by surgical resection and pathology were retrospectively analysed. According to the pathological results, all cases were divided into two groups (the invasive group and non-invasive group). Image analysis included tumour number, location, size, shape, calcification, haemorrhage, fibrous pseudo capsule, and the proportion of cystic or solid component. The density of the solid components in all lesions was measured in plain scan, the arterial phase, and venous phase of CT images. The differences between the two groups were statistically analysed.
Results: All 103 cases of pSPN had a single lesion. 38 cases were in the invasive group and 65 cases were in the non-invasive group. There were statistically significant differences in the fibrous pseudo capsule and the proportion of cystic or solid component between the two groups (P<0.05). There were no significant differences in neoplasm maximum diameter, location, morphology, calcification, haemorrhage, pancreaticobiliary dilatation, and pancreatic atrophy between the two groups (P>0.05). The density in the venous phase (76.65±16.71) in the invasive group was higher than that in the non-invasive group (70.09±12.02) and the difference was statistically significant (P<0.05).

Conclusion: The pSPN has no capsule or incomplete capsule, more solid components, and obvious enhancement of the solid components in the tumour in the venous phase, which may suggest that the tumour has more invasive behaviour.
Limitations: There was no delay scan for CT scans.
Ethics committee approval: The retrospective study was approved by the institutional review board of our hospital.
Funding: No funding was received for this work.

The rate of muscle loss measured with CT is a prognostic marker in patients with unresectable pancreatic cancer receiving FOLFIRINOX
E. Salinas-Miranda, F. Khalvati, D. G. O'kane, X. Dong, D. J. Knox, O. Bathe, V. Baracos, D. S. Gallinger, M. A. Haider*; Toronto, ON/CA (emmanuels7@gmail.com)*

Purpose: To assess the prognostic value of body composition biomarkers assessed by CT in pancreatic cancer patients (PC) undergoing FOLFIRINOX chemotherapy.
Methods and materials: We analysed the pre-treatment and first follow-up CT of 64 PC patients enrolled in a trial receiving FOLFIRINOX. Skeletal muscle, intraabdominal fat, subcutaneous fat, and intramuscular fat were measured as normalised cross-sectional areas (cm^2/m^2) at the L3-level. SliceOmatic software v5.0 was used. We calculated the rate of muscle loss (RML) over a follow-up time of 90 days. The associations between CT body composition measurements and clinical variables with time to progression (TTP) and overall survival (OS) were determined using a Cox proportional hazard analysis. Statistically significant variables in univariate analysis were included for multivariate analysis.
Results: In the multivariate analysis, the rate of muscular loss was significantly associated with OS and TTP, with a hazard ratio (HR) of 2.61 (CI: 1.37-4.95, p=0.003) and 1.92 (CI: 1.17-3.15, p=0.009), respectively. The optimal cut-point of RML was 8.18 cm^2/m^2 per 90 days for OS (HR:2.21, CI: 1.23-3.98, p<0.007) and 6.02 cm^2/m^2 per 90 days for TTP (HR:2.95, CI: 1.5-5.46, p<0.001). None of the remaining body composition measurements was associated with OS or TTP in multivariate analysis. RML remained significant in the prognostication for OS while the RECIST status at the first follow-up did not.
Conclusion: In patients with locally advanced and metastatic PC, the high RML between the first and second CT is associated with worse survival and earlier tumour progression.
The RML from baseline to the first follow-up CT in patients receiving FOLFIRINOX may add value to response prediction in PC and help with therapy modulation or nutritional intervention. Further prospective validation is required.
Limitations: A retrospective study with a low sample size.
Ethics committee approval: IRB approved the study.
Funding: Ontario Institute for Cancer Research and the Translational Research Initiative in Pancreatic Cancer and Clinician Investigator Program was granted to Masoom Haider.

Diagnostic value of attenuation measurement of the kidney on unenhanced helical CT in obstructive urolithiasis
H. H. Shanbhag*; Mumbai/IN (harshitha.shanbhag91@gmail.com)*

Purpose: The aim of this study was to evaluate the diagnostic value of attenuation measurement of kidney on NCCT (non-contrast CT) in comparison with other secondary signs of obstructive urolithiasis.
Methods and materials: 150 patients with acute unilateral flank pain, above the age of 18 years underwent NCCT, 50 control subjects admitted for other acute abdominal emergencies without urinary complains were included. Attenuation values were measured with ROI (40 mm^2) in upper, middle, lower portion of renal parenchyma (cortex). Mean attenuation value (Hounsfield units) was calculated for each kidney. A difference in mean attenuation values was calculated . Presence or absence of hydroureter, perinephric fat stranding, soft tissue rim surrounding the ureteral stone was noted.
Results: Among 150 patients with documented renal stones, mean attenuation of obstructed kidneys was 28.81+/-2.18HU (range 26.63-30.99). Mean attenuation in controls was 36.40 +/- 2.93 (range 33.47-39.33). A renal parenchymal density difference of 5.4 HU or greater had 86.26% sensitivity, 98.26% specificity, 99.17% positive predictive value, 69.36% negative predictive value, and 86% accuracy in predicting the presence of acute obstructing ureteral stone. It was more sensitive, specific and accurate compared to secondary signs such as hydroureter, perinephric stranding and soft tissue rim sign.
Conclusion: Renal parenchymal density difference of greater than or equal to 5.4HU is valuable sign of acute ureteral obstruction which showed better diagnostic accuracy than other secondary signs with advantage of being the only measurement-based parameter.
Limitations: Due to retrospective design, relationship between attenuation difference and duration of pain could not be evaluated.
Ethics committee approval: Institutional ethics committee approval was obtained. Written informed consent was taken from patients prior to the scan.
Funding: No funding was received for this work.

Predictors of infectious complications following transrectal ultrasound-guided prostate biopsies in an Irish prostate cancer centre
R. R. Durganaudu, M. M. Morrin, R. Dunne*; Dublin/IE (durganar@tcd.ie)*

Purpose: The incidence of infectious complications following transrectal ultrasound (TRUS)-guided prostate biopsies is on the rise. In this study, we compared post-biopsy infection rates in patients who underwent mp-MRI targeted vs non-targeted TRUS-guided biopsies, and also aimed to identify other predictors of infectious complications.
Methods and materials: Retrospective review was performed on 525 patients who underwent TRUS biopsies in Beaumont Hospital between 1/01/2017 and 31/07/2018. Infection rates in both targeted and non-targeted biopsy groups were compared using Pearson's chi-square test. Other characteristics of patients with and without infections were compared using Mann-Whitney U test, Pearson's chi-square test and Fisher's exact test as appropriate. Binomial logistic regression analyses were then performed to identify possible predictors of infectious complications.
Results: Infectious complications occurred in 20 (3.8%) out of 525 patients. A total of 209 (39.8%) biopsies were targeted. Of the 20 patients who developed infectious complications, seven (35%) underwent targeted biopsies. The difference in infection rates in targeted and non-targeted biopsy groups was not statistically significant. Analysis of other associated patient characteristics revealed significantly higher median prostate-specific antigen (PSA) values in patients who developed infectious complications (p<0.05). On binomial logistic regression, none of the variables investigated were found to be significant predictors of infectious complications in our institution.
Conclusion: Rising infection rates post TRUS-guided biopsies is a concerning trend with significant implications. While our study did not identify any statistically significant predictors of infectious complications in our institution, it had helped uncover areas of research that could be explored further to help shape future policies.
Limitations: This study was limited by (1) small sample size, (2) retrospective nature of the study which affected accessibility of some data, and (3) that it is a single centre study.
Ethics committee approval: Approved audit.
Funding: No funding was received for this work.

Retrospective study of endovascular therapy for renal bleedings of arterial origin
A. Fialkovska[1], B. Glodny[2], J. Petersen[3]; *[1]Mannheim/DE, [2]Innsbruck/AT, [3]Birgitz/AT*

Purpose: It was intended to compare interventional super-selective embolisation regarding renal parameters, clinical course and outcome to other therapeutical options and by that improving the approach to the treatment of acute renal bleedings of arterial origin.
Methods and materials: Patients with renal injuries due to bleeding of arterial origin, pseudoaneurysms or arteriovenous fistulas underwent transcatheter arterial embolisation. The analysis included data of the technical and clinical success of embolotherapy, differences performing endovascular treatment during the clinical course and whether the post-interventional modified parenchymal renal volume amplifies the risk of developing renovascular hypertonia and chronic kidney disease.
Results: A total of 167 patients was included. The technical success rate was 100 % and a clinical success rate of 92.5 % was achieved. Recurrent bleeding occurred in 14 patients (8.4 %). 6 (42.9 %) were re-embolised and 5 (35.7 %) underwent total nephrectomy. Recurrent bleedings tended to occur in correlation with subcapsular haematomas ($p < 0.001$). Renal function was measured by glomerular filtration rate and creatinine several times. It revealed no significant changes ($p > 0.05$). Patients with discontinuity of renal fascia were at a higher risk of parenchymal loss ($p = 0.0237$). The post-interventional renal volume loss was insignificantly low and over a period of 15 years, neither contributed to the progression of renovascular hypertonia nor to deterioration of renal parameters.
Conclusion: This study verified that there was neither a positive correlation between a reduced post-interventional parenchymal renal volume and a progression of renovascular hypertonia nor deteriorating renal laboratory parameters. Furthermore, the choice of embolisation material and the appropriate catheter-technique are decisive for reducing fluoroscopy time.
Limitations: Not all the patients' data was available.
Ethics committee approval: n/a
Funding: No funding was received for this work.

MyT3 15-4 14:12
Multivessel Doppler in the evaluation of IUGR
H. Pobbati*; Hyderabad/IN (hvardhan2004@gmail.com)*

Purpose: To evaluate the role of colour Doppler sonography in the evaluation of pregnancy with intrauterine growth restriction. The uteroplacental circulation, which are the two maternal uterine arteries. The foeto-placental circulation, which is the umbilical artery. The foetal circulation, which includes the foetal middle cerebral artery.
Methods and materials: The study included 30 antenatal women who were diagnosed as having a foetus with intrauterine growth restriction based on greyscale ultrasound findings and referred for obstetric Doppler ultrasound if the following inclusion criteria and exclusion criteria were met. The inclusion criteria were: singleton pregnancy with a gestational age of more than 28 weeks. Women with reliable dating of pregnancy confirmed by an early first-trimester ultrasound examination using CRL or BPD or with known LMP will be selected. Multiple pregnancies and foetuses with congenital anomalies. Doppler US evaluation was performed following a detailed clinical history and US biometry. The scanners and transducers used: the greyscale real-time ultrasonographic examinations were performed using ALOKA PROSOUND SSD – 3500SX and PHILIPS HD 11XE. The transducers used for the study were 3.5MHz convex array transducer.
Results: The sensitivity of uterine artery Doppler study to detect adverse perinatal outcome was 83% when two Doppler parameters were considered.
Conclusion: Assessment of both the uteroplacental circulation and the fetoplacental circulations together is more sensitive to predict a perinatal outcome, than the assessment of each alone. In suspected IUGR, cerebro-umbilical ratio (MCA/UA PI) is a better predictor of adverse perinatal outcome than an abnormal MCA PI or umbilical artery PI. Best results are obtained when we use MCA/UA PI ratio, rather than PIs of a middle cerebral artery and umbilical artery separately.
Limitations: This study is limited by the lack of patient follow-up.
Ethics committee approval: Not applicable.
Funding: No funding was received for this work.

Magnetic resonance imaging and three-dimensional transperineal ultrasound evaluation of pelvic floor dysfunction in symptomatic women: a prospective comparative study
E. F. A. M. Tantawy, M. A. A. Basha, R. Almolla, H. Almassry*; Zagazig/EG (Dr_Engy_tantawy@yahoo.com)*

Purpose: To investigate magnetic resonance imaging (MRI) and 3-dimensional transperineal ultrasound (3D-TPUS) features of pelvic floor dysfunction (PFD) in symptomatic women in correlation with digital palpation and to define cut-offs for Hiatal dimensions that can predict muscle dysfunction.
Methods and materials: This is a prospective study included 73 women with symptoms suggesting PFD. 3D-TPUS, MRI, and digital palpation of levator ani muscle were performed for all patients. Levator hiatal antro-posterior (LHap) diameter and area (LH area) were measured at rest and at maximum muscle contraction.
Results: The reduction in LHap diameter and LH area during contraction was significantly less in women with underactive pelvic floor muscle contraction (UpfmC) than those who have a normal pelvic floor muscle contraction (NpfmC) by digital palpation ($p <0.001$). Statistically significant positive correlations ($p <0.001$) were found between Modified Oxford Score (MOS) and 3D-TPUS and MRI regarding the reduction in the LHap diameter ($r= 0.8, 0.82$, respectively) and LH area ($r= 0.6, 0.7$, respectively). A reduction in LHap <6.5% on 3D-TPUS and <7.6% on MRI, predicted UpfmC with sensitivities of 46% and 83%, respectively. A reduction in LH area <3.4% on 3D-TPUS and <3.8% on MRI predicted UpfmC with sensitivities of 75% and 88.5%, respectively. MRI was more sensitive in detecting levator avulsion (63%) than 3D-TPUS (27%).
Conclusion: MRI and 3D-TPUS have a strong positive correlation with palpation, and at certain cut-offs for Hiatal dimensions, they can be used as complementary and objective tools to improve the diagnosis and management planning of PFD.
Limitations: This study is limited by small sample size.
Ethics committee approval: Written consent from patients are obtained and our study was proved by our ethics committee according to the ethical principles of the Declaration of Helsinki.

Comparison of multiparametric prostate MRI and PSMA gallium PET-CT efficiency: the intraductal component and cribriform pattern in intraprostatic tumour focus
A. Arslan, M. B. Tuna, L. Güner, Y. Sağlıcan, A. R. Kural, E. Karaarslan*; Istanbul/TR (arslanaydan@gmail.com)*

Purpose: The aim of our study was to compare the efficacy of PET and MRI in detecting the intraductal component and cribriform pattern in patients with clinically significant prostate cancer who underwent radical prostatectomy.
Methods and materials: Thirty patients who underwent radical prostatectomy between June 2015 and April 2018 were included in the study. The intraductal component and cribriform pattern of each tumour focus were also identified with whole-mount histopathologic analysis correlation.
Results: The presence of intraductal component did not create a statistically significant difference in visibility of the index tumour on MRI and PET. However, in terms of total tumoral lesions, the visibility on MRI is statistically significant. The presence of cribriform pattern did not show a statistically significant difference in detection of the tumour on MRI and PET.
Conclusion: Cribriform pattern was found to be less visible than intraductal carcinoma by MRI.
Limitations: Our study was retrospective. It has a limited number of patients. Thirty patients were evaluated according to 67 clinically significant tumour foci.
Ethics committee approval: This study is approved by the institutional review board.
Funding: No funding was received for this work.

Comparison of ADC-ratio vs mean ADC value of multiparametric MRI to predict the aggressiveness of prostate cancer
X. Wang[1], V. Schütz[1], M. Görtz[1], D. Tichy[1], P. D. A. Stenzinger[1], M. Hohenfellner[1], H.-P. Schlemmer[1], D. Bonekamp[2]*; [1]Heidelberg/DE, [2]Hirschberg/DE (xianfeng.wang@dkfz-heidelberg.de)*

Purpose: To evaluate the usefulness of various apparent diffusion coefficient (ADC) ratios vs ADC in determining the aggressiveness of prostate cancer (PCa).

Methods and materials: 261 consecutive patients who underwent 3T MRI on a single scanner followed by MRI-transrectal US fusion biopsy within one month were included. A board-certified radiologist retrospectively reviewed all MRIs blinded to clinical information and placed 3D regions of interest (ROI) on focal lesions. Mean ADC (mADC) of each lesion and reference regions: normal-appearing peripheral zone (PZNL) and transition zone (TZNL), right and left internal obturator muscle (RIOM, LIOM), and the urinary bladder were calculated. Different ADC ratios were calculated as mADC/reference. Clinically significant PCa (sPC) was defined as Gleason Grade Group≥2. Independent t-test was used to differentiate the ADC metrics between sPC and non-sPC. Receiver operating characteristics (ROC), and the DeLong test was used to assess the differences of the area under the curve (AUC, 95%-CI).
Results: 392 lesions (302 in the peripheral zone) found in 253 men were included in the final study cohort. ADC metrics except ADC ratio (RIOM,LIOM) (p=0.43 and 0.53) showed a statistically significant difference between sPC and non-sPC (P<0.01). mADC showed the highest ROC-AUC of 0.67([0.61;0.72]),followed by ADC ratio PZNL with ROC-AUC of 0.66([0.60;0.71]) while, e.g. ADC ratio TZNL had ROC-AUC of 0.60 ([0.54;0.66]) which was significantly lower compared to mADC (p=0.002).
Conclusion: A highly standardised single-scanner ADC measurement could not be improved upon using any of the ADC ratio parameters.
Limitations: ADC ratios may still be advantageous when comparing data from multiple scanners and institutions.
Ethics committee approval: The institutional ethics committee approved the study and waived written informed consent (S-156/2018).
Funding: No funding was received for this work.

Radio-frequency ablation of renal cancer T1a with externally cooled multitined expandable electrodes
F. Pagnini, U. V. Maestroni, S. Ferretti, S. Buti, M. de Filippo*; Parma/IT (f.pagnini90@gmail.com)*

Purpose: To retrospectively evaluate the mid-term outcomes of percutaneous radio-frequency ablation (RFA) with multitined expandable electrodes externally cooled with saline solution in patients with T1 renal cell carcinoma (RCC).
Methods and materials: In this retrospective study, we evaluated 53 RCC in 47 patients treated with CT-guided RFA in 56 procedures (2015-2019). All patients were staged T1, N0, M0 prior to RFA. Mean tumour size was 23.79 mm. A 4-tined expandable RFA electrode cooled with pump-circulating saline was used. Efficacy was evaluated verifying complete tumour necrosis (no contrast enhancement on imaging) at the end of the procedure and on subsequent controls. Follow-up observation period was 5 years. Minor/major complications, hospitalization days, serum creatinine before-after RFA (compared using paired t-test) and pain (evaluated with NRS) were considered as safety indicators. Overall survival was also calculated (Kaplan-Meier method).
Results: Of 47 patients, 40/47 had 1 treatment (primary effectiveness rate 87,5%), 5/47 had 2 treatments and 1/47 had 3 treatments for residual disease, 1/47 had 3 treatments for multiple RCC. There were no relapses, no mid-long term complications; 5 minor (8,9%) and 1 major (1,7%) complications during the perioperative period were reported. Mean before and after RFA serum creatinine rates were respectively 1.08 mg/dl and 1.11 mg/dl (p-value: 0.4117). NRS median value: 0.8. Hospitalisation days median value: [2.8 ± 1.9] days. 91,4 % of all patients survived, with a median overall survival time of 65 months.
Conclusion: Mid-term results show that CT-guided RFA with multitined expandable electrodes externally cooled with saline solution is an effective and safe treatment in patients with RCC staged T1N0M0. Data reported in our study are in line with data reported in the literature from patients treated with other devices.
Limitations: This is a monocentric study, observing few cases.
Ethics committee approval: n/a

Role of MRI to evaluate kidney volume in AKPD patients
G. Di Nino, E. Grassedonio, M. Guarneri, L. La Grutta, G. Salvaggio, F. Midiri, M. Galia, T. V. Bartolotta, M. Midiri*; Palermo/IT*

Purpose: Patients with ADPKD (autosomal dominant polycystic kidney disease) show a progression disease hard to predict with common prognosis factors. We know the gradual expansion of the cysts increases the renal volume. A prognostic classification based on the renal volume measured with magnetic resonance imaging (MRI) corrected for height and age (HtTKV, height-adjusted total kidney volume) was developed. The proposed classification defines 5 classes (from A to E) of patients with a different risk of GFR decline based on renal growth rate and annual GFR reduction.
Methods and materials: 25 patients (age 24-57) with ADPKD (14F / 11M) were followed clinically and radiologically with abdominal MRI (GE 1.5T, T1, T2, DWI). The MRI was used to calculate HtTKV. The renal volume was calculated by the Mayo clinic's web-based programme and MRI images by an algorithm based on the ellipsoid equation (π / 6xLxWxD), 4 major measurements (L,W,D,coronal, sagittal ,axial sequences), then correlating these values to the patient's age and height, GFR, we obtained the patient class.
Results: The GFR range was (12-128) and the HtTKV (230 and 2078 mL/m). The patients were divided in 5 classes (4 class A, 7 B, 6 C, 5 D, 3 E). Patients in class A had normal value, 1/7 class B (GFR <60 ml / min / 1.73m2), class C: 4/6 (GFR <60 ml / min / 1.73m2).
Conclusion: Our study shows the utility of renal MRI-based volume in patients with ADPKD to analyse prediction factors.
Limitations: This study was limited by the number of patients due to a rare genetic disease.
Ethics committee approval: n/a

Texture analysis of MRI for differential diagnosis of renal masses
M. Erşen[1], H. T. Sanal[1], M. Taşar[1], A. Keskin[2], M. Ş. Güneş[2]; [1]*Ankara/TR,* [2]*Istanbul/TR (mehmetersen@gmail.com)*

Purpose: The purpose is to investigate texture analysis findings', the structure analysis application in radiological imaging, efficacy in the differential diagnosis of kidney masses renal cell carcinoma (RCC) and oncocytoma, contribution to the classification of RCC subtypes and relationship with the nuclear stage of RCC.
Methods and materials: Retrospectively 32 patients who underwent renal MRI between November 2016-2018, having pathological diagnosis were included. The cases were divided into groups according to their pathological diagnoses (21 clear-cell-RCC, five papillary-RCC, three chromophobe-RCC, three oncocytoma; out of 21 clear-cell RCC cases 10 were low-stage, 10 were high-stage). Texture feature selection/extraction processes were applied on 2D axial images with MaZda software. Fisher's coefficient and POE+ACC methods were used for feature selection. Features were analysed with canonical discriminant analysis.
Results: The success rate in distinguishing the RCC subtypes from each other and from oncocytoma were found to be different when images of different sequences were used. With the evaluation of texture parameters on T2W and 70 sec contrast-enhanced T1W, 100%; SPAIR-T2W 89.3%, ADC 75.9%, out-of-phase 93.3% and 30 sec contrast-enhanced T1W 95% of the cases were classified correctly. All of the cases were classified correctly according to the data on ADC and 70-sec contrast-enhanced T1W images, the sequences which were used in distinguishing between low stage and high stage of clear cell RCC cases.
Conclusion: Texture-based analysis parameters can be used on MRI in differentiating RCC from oncocytoma, in classifying the RCC subtypes, and in discriminating clear-cell-RCC nuclear stage.
Limitations: Small size of case groups, the absence of lipid-poor angiolipoma and three different MR devices for image acquisiation were the main limitations of this study.
Ethics committee approval: Non-invasive ethical approval was obtained.
Funding: No funding was received for this work.

68Ga-PSMA PET/CT in biochemically recurrent prostate cancer: when do we miss it and why?
I. Zelsky; *Yekaterinburg/RU (zelskii78@gmail.com)*

Purpose: 68Ga-PSMA PET/CT is being increasingly used for prostate cancer recurrence identification, however, the detection rate among patients varies from 66% to 85%. The aim of our study was to analyse the influence of several variables on the detection rate, some of them with possible influence on PSMA expression.
Methods and materials: This was a retrospective study of 312 men with biochemical failure after radical prostatectomy or radiation therapy, with or without ongoing androgen deprivation therapy (ADT), who received a 68Ga-PSMA PET/CT between 05/2018 and 08/2019. The goal was to determine the relationship among pre-scan PSA level, PSA doubling time, PSA velocity, Gleason score, ADT and the probability of identifying PSMA-avid disease. For statistical analysis, a p-value of <0.05 was considered statistically significant. Univariate and multivariate logistic regression analysis was applied.
Results: In 77% of patients, at least a single lesion with characteristics suggestive of recurrent PCa was detected. A positive 68Ga-PSMA PET/CT scan was associated with PSA doubling time and ADT.
Conclusion: We think that blockade of androgen receptor (AR) signalling oncogenic pathway activates phosphoinositide 3-kinase (PI3K) pathway, which leads to rapid PSA increasing and PSMA overexpression. So, in a patient with ADT we can detect a very small amount of tumour cells. But AR and PI3K signalling pathways have the reciprocal negative feedback loop, so activated AR inhibits PSMA expression. Therefore, patients without ongoing ADT have less PSMA on tumour cells, and detection thereof using a PSMA-ligand requires more tumour volume. Probably due to this fact we miss small tumour lesions in patients with low PSA values and without ongoing ADT using 68Ga-PSMA PET/CT.
Limitations: Not all variables were available for all patient.
Ethics committee approval: Written informed consent was obtained.
Funding: No funding was received for this work.

Multiple mathematical models of diffusion-weighted imaging for evaluation of prognostic features in endometrial cancer
O. Zhang, X. Zhao, H. Ouyang; *Beijing/CN (18810683722@163.com)*

Purpose: To investigate monoexponential, biexponential, and stretched-exponential models of diffusion-weighted imaging (DWI) for the assessment of prognostic features in endometrial cancer (EC).
Methods and materials: 61 consecutive EC patients confirmed by pathology underwent multiple-b value DWI (0-1200s/mm^2) preoperatively at 3.0T MR scanner. The apparent diffusion-weighted (ADC), biexponential model-derived parameters (D, D* and f) and stretched-exponential model-derived parameters (DDC and α) were measured by two radiologists independently. All parameters were compared between the deep and superficial of myometrial invasion, with and without cervical stromal infiltration (CSI), presence and absence of lymphovascular invasion(LVSI). ROC curve and intraclass correlation coefficient analysis were used for statistical evaluation in predicting prognostic factors of EC.
Results: Except for D* values, all of the parameters were significantly lower in tumours with deep myometrial invasion(DMI) than those invading superficial myometrial wall and the AUC was largest for ADC values(AUC:0.794). There was a significant difference between groups with and without CSI for ADC and f values and the f values exhibited best diagnostic performance in the prediction of CSI(AUC:0.825). The presence of LVSI had significant lower ADC, f and DDC values than those absences of LVSI and the DDC values showed the best diagnostic performance in the diagnosis of LVSI (AUC:0.759).
Conclusion: The current study demonstrated that the prediction of prognostic factors for EC is feasible by multiple mathematical DWI models, which could be conducive to the pre-treatment risk classification to facilitate the selection of the optimal therapeutic approach and meet the demand for greater personalisation of cancer care.
Limitations: It was a single-centre study with relatively small sample size and 13 b-values for the multiple b-value of DWI protocol prolonged the scan time.
Ethics committee approval: Information about review board approval and written informed consent.
Funding: No funding was received for this work.

High b-values in DWI for prostate cancer detection: what to acquire and what to compute?
M. Schoeniger[1], H. Seuss[1], F. Laun[1], J. Martin[1], T. Kuder[2], R. Janka[1], A. Cavallaro[1], M. Uder[1], M. Hammon[1]; *[1]Erlangen/DE, [2]Heidelberg/DE (Hannes.Seuss@googlemail.com)*

Purpose: The aim of this study was to compare the diagnostic quality of acquired and computed high b-value images in diffusion-weighted magnetic resonance imaging (DWI) of the prostate in a setting, where the signal-to-noise ratio (SNR) is increased at high b-values by means of larger voxel sizes.
Methods and materials: 34 patients with a PI-RADS 4/5 lesion in the peripheral zone were included. DWI was acquired (aDWI) with four b-values (0, 800, 1500, and 3000 s/mm²) at 3T. The nominal resolution was adapted to roughly keep the SNR constant. Computed-DWI (cDWI) were generated with the respective unweighted image and the acquired b-values, e.g. b3000 from b0 and b800 (cDWI3000-800). This resulted in two acquired and two computed images for each b-value (including b0) summarising to ten images. The three b0 images were pooled. Four readers performed a forced-choice pairwise comparison for representative lesions of all ten images and assessed lesion conspicuity and the ability to locate the lesion.
Results: Concerning lesion conspicuity, cDWI3000-1500 scored highest (6.71) followed by cDWI1500–800 (5.71), and cDWI1500–3000 (5.14). For the ability to localise the lesion, cDWI800-1500 scored highest (5.82), followed by aDWI800 (5.41), and cDWI1500-3000 (5.40).
Conclusion: In this study diagnostic performance of DWI in prostate magnetic resonance imaging was achieved for the combination of acquired b1500 and computed b3000. Therefore, we recommend to acquire images as high as b1500 and to compute the remaining images.
Limitations: Potentially the most important limitation is that whole-mount prostate histology data were not available because prostatectomy is rarely performed at our hospital.
Ethics committee approval: Institutional review board approval was obtained.
Funding: This study has received funding by the Deutsche Forschungsgemeinschaft (grant LA 2804/6-1).

Multiparametric magnetic resonance imaging (mp-MRI) in the evaluation of prostate cancer based on PIRADS V2 on 1.5 T without endorectal coil
S. M. Ingole, R. U. Mehta, Z. Kazi; *Mumbai/IN (ingole.sarang@gmail.com)*

Purpose: To evaluate the role of multiparametric magnetic resonance imaging (mp-MRI) for the assessment of prostate cancer based on PIRADS V2 on 1.5T without endorectal coil.
Methods and materials: 45 patients with clinical suspicion of prostate cancer were retrospectively evaluated by 18 channel 1.5T MRI with body matrix coil, over a period of 24 months. All cases were evaluated using mp-MRI protocol i.e. T2W with DWI, DCE; interpreted using PIRADSv2 and correlated with histopathology.
Results: Mean age was 67 years and mean PSA was 38.2 ng/ml. 86% of all malignancies were in the peripheral zone. 80% of the cohort had prostate cancer, 11% had BPH and 9% had chronic prostatitis. PIRADS score for T2W showed good sensitivity (81%) but low specificity (67%) while PIRADS score for DWI with a sensitivity of 92% and specificity of 78% had overall accuracy better than T2W alone. Mean ADC value (x 10-6 mm2/s) was 732±160 in prostate cancer, 1009±161 in chronic prostatitis, 1142 ± 82 in BPH and 663 in case of microabscesses. Low ADC values (<936) has shown good correlation (AUC-0.87) with the presence of cancer foci. An inverse correlation was observed between Gleason score and ADC values in proven cases of cancer. DCE has shown 100% sensitivity / NPV, but moderate specificity (67%) in predicting malignancy. The final PIRADS score had almost 100% sensitivity and NPV with good overall PPV (95%).

Conclusion: T2W and DWI remain mainstay in diagnosis of prostate cancer on mp-MRI. DCE can be problem solving tool. Because assessment on mp-MRI can be subjective, use of PIRADSV2 guidelines are helpful in accurate interpretation.
Limitations: The endorectal coil was not used and sample size was small.
Ethics committee approval: n/a

Detection of peritoneal metastases from ovarian cancer: a comparison between 3T MRI and surgical findings
M. A. Szadkowska, J. P. Pałucki, J. Kuśnierz, M. E. Gumowska, K. Sloboda, J. M. Poziemska, M. Bidziński, A. Cieszanowski*; Warsaw/PL (maszadkowska@hotmail.com)*

Purpose: The aim of this study was to assess the effectiveness of 3T MRI in the detection of peritoneal carcinomatosis from ovarian cancer using intraoperative findings as a reference.
Methods and materials: 25 patients diagnosed with ovarian cancer, aged between 35 and 69 (mean age - 54), underwent MRI examinations at our institution between March 2017 and November 2018. The inclusion criteria were: pathologically confirmed diagnosis of ovarian cancer, preoperative 3T MRI examination performed at our institution, potentially resectable peritoneal metastases, eligibility to cytoreductive surgery (CRS, potentially followed by HIPEC procedure). The examinations were performed using a 3T MRI scanner. The MRI protocol included T1W-sequences (coronal and axial) before and after administration of gadolinium-based contrast agent, T2W-sequences (coronal and axial) and axial DWI/ADC scans. The patients underwent surgical exploration of the peritoneal cavity and the findings were reported according to PCI-scale (Peritoneal Carcinomatosis Index). The studies were retrospectively analysed by an experienced radiologist with a special interest in urogenital radiology and PCI scores were assigned and compared region to region to the results of the surgical evaluation.
Results: The overall sensitivity and the overall specificity of MRI were 60,00% and 73.94, respectively. MRI proved to be the most sensitive in region 6 (pelvis, 91,67%), 1 (right upper region, 83,33%) and 4 (left flank, 72,73%), whereas the lowest sensitivity was noted in small bowel and small bowel mesentery (regions 9- 25%, 10- 37.50%, 11- 25% and 12 - 42.86%).
Conclusion: The preoperative 3T MRI proved to be moderately effective, yet still useful, in the detection of peritoneal carcinomatosis from ovarian cancer.
Limitations: The limitations of this study were: retrospective design, relatively small sample.

Documenting the radiation diagnosis of stress urinary incontinence in females
H. Nechyparenka*; Grodno/BY (salejanna@mail.ru)*

Purpose: Improving the efficiency of diagnostics of cystocele and stress urinary incontinence (SUI) using methods of diagnostic radiology.
Methods and materials: A comprehensive examination of the data of 73 patients with genital prolapse (GP) with the help of a modified Pad-test and MRI.
Results: We modified the well-known Pad-test by intravenous injecting of solution of indigocarmine and an iodine-containing contrast preparation. After the test, a visual assessment of the sanitary pad and it's radiography was done. The main advantage of the modification is the ability to visually confirm the fact of involuntary loss of minimal volumes of urine by detecting the spot of indigocarmine on the sanitary pad and the contrast stain on the x-ray film of the pad after Pad-test. A colored spot on the pad and a contrasting shadow on the roentgenogram of the gasket is a documentary confirmation of the involuntary loss of the contents of the bladder – a sign of SUI. The procedure was used in 21 patients who suspected a minimal SUI. A positive Pad-test is a documentary confirmation of minimum volume SUI and an indication for MRI investigation. If, according to the results of static MRI, damage of the ligaments of the urethra and/or value of the urethral inclination angle (UIA) is more than 30º, a dynamic MRI needs to be done. At values of UIA according to the results of dynamic MRI over 35º, cystocele is diagnosed and classified.
Conclusion: The modified Pad-test confirms and documents the minimum SUI. An MRI of the pelvis detects and documents all cases of the presence of SUI in women with GP, allows for an objective diagnosis of the cystocele.
Limitations: No limitations identified.
Ethics committee approval: The positive decision of the ethics committee obtained.
Funding: No funding was received for this work.

Dual-energy computed tomography in the diagnostics of urolithiasis
L. Kapanadze, N. S. Serova, V. Rudenko, K. Alexandrova*; Moscow/RU (Lidakap@rambler.ru)*

Purpose: To assess the diagnostic possibilities of dual-energy computed tomography (DECT) in the evaluation of urinary stones composition "in vivo".
Methods and materials: A total of 91 patients: men (n=68; 75%) and women (n=23; 25%) aged from 20 to 70 years old with urolithiasis were examined at Sechenov University. Before the surgery, all patients underwent DECT (Canon, Japan) in order to predict the chemical composition of urinary stones in vivo. Shockwave lithotripsy (SWL) was performed in 53 patients (58,2%), percutaneous nephrolithotripsy (PCNL) – in 18 (19,7%) patients, ureterolithotripsy (URS) – in 20 (22,1%) patients. In the postoperative period, all the stones or their fragments (n=91; 100%) were examined using a comprehensive physicochemical analysis (x-ray phase analysis, electron microscopy, infrared spectroscopy).
Results: In order to increase the diagnostic efficiency of DECT, we performed a comprehensive analysis of five specific DECT indicators (stone density at 135 kV, Z eff of the stone, DER, DEI, DED) using discriminant analysis instead of the one indicator - the dual-energy ratio (DER) - which is more commonly used. Using discriminant analysis with five specific DECT indicators resulted in higher values of sensitivity, specificity and overall accuracy: for vevellite – 95,2%, 89,8%, 92,3%, for Ca-containing stones without vevellite – 85,3%, 96,4%, 92,3% and for uric acid and struvite stones – 100%, 100%, 100%.
Conclusion: Dual-energy computed tomography in the preoperative period is a highly informative method for reliable assessment of the chemical composition due to its high diagnostic value. DECT in patients with urolithiasis allows optimising the tactics of surgical treatment and the individualisation of metaphylaxis taking into account the type of stone formation.
Limitations: No limitations identified.

Dynamic perfusion computed tomography in assessing of urogenital allografts
I. O. Shchekoturov, R. F. Bakhtiozin, A. L. Istranov*; Moscow/RU (samaramail@bk.ru)*

Purpose: To demonstrate the technique and possibilities of perfusion computed tomography in assessing of the urogenital allografts state.
Methods and materials: We examined 36 patients (n = 100%) using dynamic perfusion computed tomography. 27 of them (n = 75%) diagnosed with transsexualism, underwent a female-to-male sex change operation using phalloplasty and consistent urethroplasty after 6 months. 9 (n = 25%) patients had different urogenital diseases such as: posttraumatic urethral stricture, microphallia etc. A free revascularised microsurgical allograft - skin-muscular thoracodorsal was used for the reconstruction of the penis, and for the reconstruction of the urethra was used skin-fascial radial allograft.
Results: Processing of the data showed that in the early postoperative period there was a decrease in the level of arterial blood flow in the allograft tissue compared with preoperative indicators due to congestion and oedema. Then, an gradually increase in the level of arterial blood flow is observed due to the formation of anastomoses between the flap and the recipient's tissues and the further improvement of their function, as well as a decrease in the severity of oedema and congestion in the flap. The blood flow recovery in the flap to normal preoperative values was registered by the end of the first month after surgery.
Conclusion: Dynamic perfusion CT is a more modern and advanced diagnostic method for grafts assessing than three-phase computed tomography. This method provides additional information about allograft state and allows to

measure perfusion indicators at the capillary level with high spatial and temporal resolution in numerical values.
Limitations: There is no limitations.
Ethics committee approval: The study was approved by the Institutional Review Board of Sechenov University, and informed consent was obtained from all study participants.
Funding: No funding was received for this work.

Bladder pathology: is it that easy?

C. A. B. Oliveira, V. Mendes, A. C. G. Costa*; Braga/PT*
(carlosaboliveira2014@gmail.com)

Purpose: To review bladder pathology with a multimodality approach and to define criteria when bladder pathology was found.
Methods and materials: Review 300 cases with bladder pathology.
Results: The bladder can be approached by many modalities. Ultrasound provides anatomic detail, vascularity and nodules identification. CT is the next step and the gold standard with uro-CT the most commonly used protocol. The six points were defined: (1) imaging findings, (2) ureterovesical junction (UVJ) permeability, (3) bladder wall thickness, (4) presence of nodules/masses, (5) neurogenic bladder, (6) pelvic masses and other findings. The imaging findings included: ultrasound a wall focal (nodule) or diffuse parietal thickening, vascularity; CT - diffuse or nodular parietal thickening with enhancement. 53% of patients had pathology of the UVJ including lithiasis, masses and compression. Bladder wall thickness was defined as pathologic superior to 3mm when distended and superior to 5. Nodules/ masses from the bladder where found in 13 %, from the ureter in 4 % and form the prostate in 3 % of cases, adnexal masses and uterine masses in 12 %. Signs of the neurogenic bladder were present in 64 % of cases and graded from mild to moderate and advanced. Other findings included lithiasis, other urothelial cancers, and intestinal pathology.
Conclusion: Bladder pathology is a common problem for radiologists and careful attention and awareness are a demand.
Limitations: This study is limited by one-radiologist read and its limited sample.

Renal duplex in evaluation acute glomerulonephritis in children with laboratory and histopathological correlation

R. M. Ellessy[1], R. H. Hashem[2], S. M. Kamel[1], D. Salah[1]; [1]*Giza/EG,* [2]*Cairo/EG*
(rehamellessy@gmail.com)

Purpose: Acute glomerulonephritis is an entity of renal disease in which immunologic mechanism cause damage to the basement membrane. The current study evaluates the renal vascular resistance in patients with acute glomerular diseases by measuring main renal and intrarenal arterial resistance (upper, mid and lower polar) (RI) of both kidneys and to correlate with laboratory data (creatinine, proteinuria) and histopathology.
Methods and materials: The study was conducted on twenty (20) patients with the age ranging from 3-13 years old. Cases with a non-glomerular cause of acute kidney injury, obstructive uropathy and known reno-vascular lesion were excluded from the current study.
Results: The mean RI of either main renal or parenchymal arteries is elevated in tubulointerstitial affection (mean value in main renal = 0.65, mean value in parenchymal arteries = 0.62) when compared to mean RI in cases without tubulointerstitial affection (mean value in main renal arteries = 0.59, mean value in parenchymal arteries = 0.57). The presence of crescent is not correlated with RI values in main renal and parenchymal arteries, creatinine level is positively correlated (p-value 0.1) with RI of the main renal arteries, no significant statistical correlation between RI indices and proteinuria (albumin /creatinine ratio).
Conclusion: RI index of the main renal artery may assist to predict creatinine level and severity of renal dysfunction although RI is elevated in tubulointerstitial cases still can not help in differentiation between different pathological affection.
Limitations: Limitation in the current study is a small sample size. Further recommendations are to include larger sample size, renal Doppler indices correlation with further lab assessment such as B_2 microglobulin and application of artificial intelligence and soft wares to assess renal echogenicity.
Ethics committee approval: n/a

Vesicoureteral reflux imaging in paediatric patients: can cystosonography replace micturating cystourethrogram?

P. Lomoro[1], A. Citterio[1], I. Simonetti[2], A. L. Nanni[1], V. Fichera[3], L. Preda[1], M. S. Prevedoni Gorone[1]; [1]*Pavia/IT,* [2]*Naples/IT,* [3]*Florence/IT*
(lmr.pcl89@gmail.com)

Purpose: Vesicoureteral reflux (RVU) is an abnormal condition, in which urine flows backwards from the bladder to the ureters and renal pelvis. If untreated, it may lead to recurrent urinary tract infections (UTIs), reflux nephropathy chronic renal failure. Currently, micturating-cystourethrogram (MCUG) and radionuclide-cystogram (RNC) are the most commonly performed techniques for the diagnosis of RVU; both involve exposure to ionising radiations. However, in the last years, cysto-sonography (CSG) has also been introduced in clinical practice. The aim of this study is to prove the non-inferiority of CSG compared to MCUG, through a comparative analysis, in order to start introducing it as first-line technique, to reduce radiation dose.
Methods and materials: 97 paediatric patients (49 boys and 48 girls) with UTIs were enrolled in the study. As first, after positioning of a urinary catheter, each patient underwent a CSG by the intravesical introduction of contrast agent (1ml-SonoVue), immediately followed by MCUG with intravesical iodinated-contrast-medium. Passive and active RVU was sought after spontaneous urination or abdominal press operation.
Results: The comparison of the results demonstrated a consistent concordance of the findings, further confirming the sensitivity of CSG in the diagnosis of RVU in the paediatric patient. During the ultrasound examination, it was also possible to assess the renal parenchyma and the possible dilation of the calicopyelic system as further findings useful for the purposes of the diagnostic classification of the patient.
Conclusion: Cystosonography is a sensitive diagnostic technique that allows to identify RVU and to evaluate possible morphological alterations of the renal parenchyma avoiding the use of ionising radiation.
Limitations: The limitation of this study are that it is a single centre study and that it refers to a short period of time.
Ethics committee approval: Patients were enrolled in the study, after informed parental consent.
Funding: No funding was received for this work.

Computed tomography of pelvic varicocele in adolescents with urological pathology

U. Polyakova, I. Melnikov, M. Ublinskiy*; Moscow/RU (poliiinka.u@gmail.com)*

Purpose: The pathogenesis of pelvic venous insufficiency is multifactorial. Predisposing factors for the development of pelvic varicocele include a family history of varicose veins, previous pelvic surgery, aorto-mesenteric forceps, hormonal influences and multiple pregnancies in women. The purpose of this

study is to reveal the causes of pelvic varicocele in adolescents with urological pathology diagnosed by computed tomography.
Methods and materials: Three adolescents (2 girls, 14 and 17 years old, and 1 boy, 17 years old) with previously diagnosed urological pathology - pyeloectasia, had CT scan with intravenous contrast (Ultravist 370) on a 16-slice CT system and The Extended Brilliance Workspace (Philips) were used. Scanning area: abdomen and pelvis, scanning parameters: layer thickness 2,0 mm, voltage 120 kV.
Results: When analysing the images obtained, severe aorto-mesenteric forceps were detected in all patients.
Conclusion: We suppose that the main cause of varicocele in adolescents of both sexes is aortro-mesenteric forceps.
Limitations: n/a

Preoperative radiographic predictors of major vascular reconstructions in patients with testicular cancer undergoing postchemotherapy residual tumour resection (PC-RPLND)
M. Boschheidgen, A. Nini, T. Ullrich, A. Hiester, C. Winter, P. Albers, G. Antoch, L. Schimmöller*; Düsseldorf/DE (Matthias.Boschheidgen@med.uni-duesseldorf.de)*

Purpose: To provide a complete resection of residual tumour in testicular cancer patients, major vascular surgery (MVS) is necessary and requires multidisciplinary planning and adequate resources to optimise outcome. To evaluate the probability to correctly predict MVS in patients undergoing postchemotherapy retroperitoneal lymph node dissection (PC-RPLND) for testicular cancer.
Methods and materials: From 504 RPLNDs performed in 434 patients (2008-2018), 78 patients submitted to PC-RPLND after 1st line chemotherapy with MVS, like caval and/or aortic replacement or reconstruction and available preoperative CT-scans were included in this study. Preoperative imaging was reviewed blinded to operative details. Statistical analyses were performed to evaluate predictors of MVS.
Results: Of 78 patients, 16 (21%) underwent MVS. Kruskall-Wallis tests showed statistically significant differences between transverse and sagittal tumour diameter, tumour volume, cava- and aorta-tumour contact angle and contact length (in cm) ($p<0.005$). Outstanding discrimination (>0.9) was found for cava-tumour contact angle. The optimal cut-off of 5 cm for transverse tumour diameter was confirmed (SENS 0.75 and 1-SPEC 0.18, CI95% 0.8-1). Cava-tumour contact angle had SENS 0.93 and 1-SPEC 0.17 with a cut-off of 98° (CI95% 0.9-1). At MVA aorta- (cut-off 64°) and cava-tumour contact angle (cut-off 98°) and poor IGCCCG score represented the three most important predictors of MVS ($p<0.05$). The model constructed has a PPV 100%, NPV 87% and an accuracy of 88%.
Conclusion: Presence of aorta-tumour contact angle >64°, cava-tumour contact angle >98° on CT scans and poor IGCCCG score identify correctly 9 out of 10 patients requiring MVS at the time of PC-RPLND. These patients may be referred to specialised centres capable to adequately perform this multidisciplinary surgery.

Intra- and inter-rater reliability of a new osteoarthritis radiographic scale for anterior cruciate ligament deficient knees
R. E. A. Walker[1], F. Mulji[1], P. Bertiche[2], D. J. Hunter[1], D. Chan[1], N. G. Mohtadi[1]; *[1]Calgary/CA, [2]Cordoba/AR (rewalker@ucalgary.ca)*

Purpose: To compare intra- and inter-rater reliability of a new scale to the international knee documentation committee (IKDC) scale for assessing radiographic osteoarthritis (OA) in anterior cruciate ligament (ACL) deficient subjects.
Methods and materials: Preoperative/postoperative weight-bearing, bilateral posteroanterior semi-flexed radiographs from 44 subjects with ACL deficiency were presented as standard unblinded, showing surgical tunnels/hardware with the affected knee identified, and blinded, surgical tunnels/hardware digitally removed with the affected knee not identified. Radiographs were randomised and independently assessed by 3 raters for OA using a new scale and the IKDC scale on two occasions.
The new scale separately evaluates joint space narrowing (JSN), joint space uniformity (JSU), and osteophytes for both medial and lateral tibiofemoral compartments with a comparison to the unaffected side. JSN was graded as normal, detectable, obvious <50%, obvious >50%, and bone-on-bone, JSU as uniform/non-uniform, and osteophytes as present/absent.
Cohen's and Fleiss kappa statistics were used to measure the intra- and inter-rater reliability of the new and IKDC scales.
Results: Intra-rater reliability was moderate to substantial for the new scale and IKDC, except fair reliability for one rater (unblinded radiographs) for lateral tibiofemoral joint uniformity. Kappa values were statistically significant ($p<0.01$). Inter-rater reliability ranged from slight to substantial for all categories of the new scale with statistically significant Kappa values ($p<0.05$), except for agreement on lateral osteophytes (standard unblinded). For both scales, intra- and inter-rater reliability was higher for blinded radiographs.
Conclusion: Intra-rater reliability of the new OA scale for ACL-deficient knees is moderate to substantial and the same or better than IKDC. Inter-rater reliability for JSN is comparable to IKDC. Blinding surgical tunnels/hardware and the affected side may remove rater biases when assessing radiographic OA.
Limitations: The comparison to unaffected knees assumes the knee is normal.
Ethics committee approval: The study received local ethics board approval. Informed written consent was obtained.
Funding: Grant funding from Workers' Compensation Board, Alberta.

RPS 1610-2 16:06
Feasibility and reproducibility of 3D joint space mapping at the knee with standing CT data from the Multicentre Osteoarthritis Study (MOST)
T. Turmezei[1], S. B. L. Low[1], N. Segal[2], G. M. Treece[3], A. H. Gee[3], J. Lynch[4], K. E. S. Poole[3]; *[1]Norwich/UK, [2]Kansas City, KS/US, [3]Cambridge/UK, [4]San Francisco, CA/US (tom@turmezei.com)*

Purpose: Joint space mapping (JSM) can deliver 3D joint space width distribution (JSW) from CT imaging. The purpose of this study is to demonstrate its feasibility and reproducibility at the knee.
Methods and materials: 23 individuals were selected as a convenience sample from the Multicentre Osteoarthritis Study (MOST) with a full Kellgren and Lawrence grade (KLG) range. A prototype commercial cone-beam CT scanner (LineUp, CurveBeam, Warrington, PA) took fixed-flexion weight-bearing images of both knees with a 0.37 mm isotropic voxel reconstruction. JSM measured tibiofemoral JSW in 3D, with results mapped onto average joint surfaces for analysis. For feasibility, the side with worse KLG was taken, randomly if equal, for statistical parametric mapping (SPM) to ascertain the dependence of JSW

on KLG. For reproducibility, 3 knee sets were used for training of a novice, followed by a comparison of the remaining 20 against an expert.
Results: For each increment in KLG, there was a significant reduction in JSW up to 0.75 mm medially ($p<0.05$) and a non-significant increase in JSW up to 0.5 mm laterally. Global interoperator bias was -0.02 mm, the limits of agreement ±0.33 mm, and the root mean square coefficient of variation (RMSCV) 3.45%. Spatially localised results were even better with limits of agreement down to 0.1 mm and RMSCV down to 1% in central joint regions.
Conclusion: JSM at the knee is feasible, reproducible, and readily learned, meaning it could have an important role in the structural assessment of knee osteoarthritis in future research studies. The next step is to apply JSM in larger numbers to explore the relationship of 3D JSW distribution with clinical outcome measures such as pain, disability, and joint replacement.

The natural history of new horizontal meniscal tears in individuals at risk for and with mild to moderate osteoarthritis: data from the osteoarthritis initiative

M. S. Posadzy[1], G. B. Joseph[1], C. McCulloch[1], M. Nevitt[1], J. Lynch[1], N. E. Lane[2], T. M. Link;
[1]San Francisco, CA/US, [2]Sacramento, CA/US

Purpose: To study the natural history of new horizontal meniscal tears and to determine if they are associated with the progression of cartilage degeneration in individuals at risk for or with mild to moderate knee osteoarthritis over a period of 4 years.
Methods and materials: Individuals who developed a new meniscal tear in the right knee were selected from the osteoarthritis initiative cohort 3T MRIs. Knee structural changes were monitored after 4 years using a modified whole-organ magnetic resonance imaging score (WORMS). Horizontal type tears were differentiated from non-horizontal tears. The control group included individuals without a meniscal tear at any timepoint matched according to BMI, gender, race, and age. Linear regression analysis was used to compare cross-sectional and longitudinal changes in cartilage WORMS scores between the groups.
Results: 41/75 subjects (54.6%) developed horizontal tears, 24 at the medial meniscus (with 17/24 (70.8%) at the posterior horn), 16 tears at the lateral meniscus (11/16 (68.75%) at the body), and one patient developed a tear in both menisci. Over 4 years, there were 30/41 (73.2%) horizontal tears but only 22/34 (64.7%) non-horizontal tears remained stable. Individuals with a new tear had higher WORMS scores at baseline ($p<0.05$). The overall progression of cartilage degeneration over 4 years was not significantly different between horizontal tear and control groups (WORMS total knee summary score: $p>0.597$, 95%CI=-0.57-1.00).
Conclusion: New horizontal meniscal tears tended to be stable over 4 years and no statistically significant differences in overall cartilage progression were found when compared to a matched control group.
Limitations: Only subjects developing meniscal tear over a two-year period of observation were included.
Ethics committee approval: Informed consent was reviewed and approved by institutional review boards of all participating centres.
Funding: The osteoarthritis initiative is funded by the NIH.

Deep convolutional neural-network-based detection of ACL tears: a multicentre comparison of diagnostic accuracy with a surgical reference standard

C. Germann, G. Marbach, F. Civardi, S. Fucentese, R. Sutter, C. W. A. Pfirrmann, B. Fritz; *Zurich/CH*

Purpose: To clinically validate a novel, deep convolutional neural network (DCNN) for the detection of surgically proven ACL tears in a large patient cohort and to analyse the effect of MR examinations from different institutions, varying protocols, and field strengths.
Methods and materials: 512 consecutive patients were retrospectively included who underwent knee MRIs either in our (n=278) or at an outside institution (n=234), followed by knee arthroscopy in our institution. All MRIs were evaluated for a full-thickness ACL tear by three radiologists and the DCNN independently. The surgical reports served as a reference standard. Statistics included sensitivity, specificity, ROC curve analysis, and kappa-statistics. A $p<0.05$ was considered to represent statistical significance.
Results: An ACL tear was present in 45.7% (234/512) and absent in 54.3% (278/512) of patients. In comparison to any of the three readers, the DCNN showed a similar sensitivity of 96.1% (all $p\geq0.118$), but a significantly lower specificity of 93.1% (all $p<0.001$) and area under the curve (AUC) of 0.935 (all $p<0.001$). Subgroup analysis showed a significantly lower sensitivity, specificity, and AUC of the DCNN for patients examined at an outside institution (92.5%, 87.1%, and 0.898) in comparison to patients examined in our institution (99.0%, 94.4%, and 0.967), with $p=0.026$, $p=0.043$, and $p<0.05$, respectively. No significant differences of the DCNN assessments existed regarding field strength (1.5T or 3T MRI; all $p\geq0.753$). The agreement between the radiologists was almost perfect with kappa=0.984.
Conclusion: In our multi-institutional cohort (different institutions, varying protocols) our DCNN detects complete ACL tears with similar sensitivity and slightly lower specificity than specialised radiologists and with a similar accuracy than published meta-analyses.
Limitations: Possible selection bias because only patients with subsequent arthroscopic surgery were included. Only binary classification; no tear versus full-thickness tear.
Ethics committee approval: Approved by the local ethics committee.
Funding: No funding was received for this work.

Abbreviated 4 sequence protocol versus standard 6 sequence protocol for ankle MRIs: A retrospective check-list-based quantification of the value of additional sequences to the standard sequence

S. Rajan, G. Nanda, V. K. Venugopal, M. Murugavel, V. Mahajan, H. Mahajan, S. Gupta; *New Delhi/IN*

Purpose: To quantify the value provided by adding two sequences to an abbreviated 4-sequence scan protocol.
Methods and materials: This was a retrospective study of 79 MRIs of the ankle performed on a 3.0T scanner for various indications. Two sets of images were anonymised and randomised, one with three-plane FSPD and three-plane T1W images, the second with three-plane FSPD and axial T1 images. The four-sequence study was first read by two MSK radiologists with 16 years’ and 13 years’ experience using a standard 14-point checklist-based reporting template. This was followed by a washout period of 15 days and then the six-sequence study was read using the same template. The imaging findings were compared using Krippendorf’s alpha coefficient, which corrects for chance agreement.
Results: Only two features, ankle joint pathologies and subtalar articular pathologies, returned Krippendorf’s alpha scores greater than 0.67 for any radiologist suggesting no significant additional value. The other 12 features related to midtarsal joints, bones around the ankle joint, anterior talofibular ligaments, calcaneofibular ligaments, deltoid ligaments, spring ligaments, syndesmotic ligaments, lateral tendons, posteromedial tendons, Achilles tendons, anterior tendons, and plantar fascias scored below 0.67 for both radiologists implying a significant difference in the findings.
Conclusion: We conclude that the current standard of care 6 sequence multiplanar protocol offers significant additional value in 12 of the 14-checklist items as compared to the abbreviated four sequence protocol. Hence it is necessary for optimal imaging of the ankle joint.
Limitations: The relatively small number of cases.
Ethics committee approval: n/a

Graft healing following anterior cruciate ligament reconstruction: a longitudinal DTI study

P. van Dyck[1], M. Froeling[2], E. de Smet[1], P. Verdonk[3], C. H. Heusdens[1], A. Ribbens[4], T. Billiet[4]; [1]*Edegem/BE,* [2]*Utrecht/NL,* [3]*Deurne/BE,* [4]*Leuven/BE (pieter.van.dyck@uza.be)*

Purpose: To investigate the ability of diffusion tensor imaging (DTI) to monitor graft healing following anterior cruciate ligament (ACL) reconstruction.
Methods and materials: 28 patients who underwent ACL reconstruction were enrolled prospectively and invited to undergo clinical and DTI follow-up at 3, 8, and 14 months postoperatively. DTI was acquired at 3T using single-shot SE-EPI (b-values: 0/400/800s/mm^2, 10 directions; TR/TE: 1300/45ms; voxel size: 1.5×1.5×6.0mm^3; FOV 768×768×60mm). Fibre tractography (FT) was performed to delineate the ACL graft. The posterior cruciate ligament (PCL) served as a control. Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD) were calculated within the FT volumes. Data was compared using a linear mixed-effects model for all repeated measures and paired t-tests between different time points ($p<0.05$).
Results: All knees were stable during clinical follow-up. 72 DTI datasets were analysed. ACL grafts showed a significant decrease of FA over time ($F=9.05$, $p=0.003$), with the strongest decrease between 8 and 14 months postoperatively ($T=-2.55$, $p=0.002$). FA values of the PCL did not change over time ($F=0.01$, $p=0.94$). Diffusivities did not significantly change over time in ACL grafts or PCL according to the mixed-effects model ($p>0.05$). However, ACL grafts showed initial increase of diffusivities between 3 and 8 months postoperatively and decreasing values thereafter (reaching significance for AD: $T=-2.26$, $p=0.039$), while PCL showed continuing decreasing values.
Conclusion: Our study has shown the potential of longitudinally monitoring DTI values of ACL grafts following reconstruction. Our results indicate incomplete healing at 14 months postoperatively.
Limitations: A small sample size and no histological correlation.
Ethics committee approval: Approval by the institutional review board and written informed consent was obtained (B300201627688).

3D TSE MRI diagnostic accuracy compared to 2D TSE MRI for the detection of meniscal injuries with arthroscopic correlation

R. I. E. Yasin, W. A. Gouda; *Menofia/EG (rabab_yasin@outlook.com)*

Purpose: To compare 3D PD fat-suppressed space turbo spin-echo (TSE) and conventional 2D PD sequences at 3T MRI in the detection of meniscal tears.
Methods and materials: Dedicated MR knee imaging of 100 sequential patients with suspected meniscal injuries was retrospectively analysed by two independent radiologists in a novel study design using both a 2D PD standard multiplanar TSE MR technique and 3D PD TSE technique. The result was compared to arthroscopic results (arthroscopy was performed after MRI study) which were considered as a gold standard test. We determined the sensitivity, specificity, and interobserver agreement for each sequence.
Results: The 3D TSE shows statistically higher sensitivity and specificity (100% and 100%) for the detection of meniscal radial tear compared to the 2D sequence (67% and 96%). No significant difference was found between the sensitivity and specificity of both techniques regarding the detection of horizontal, longitudinal, root, flap, and bucket handle tears. There was higher interobserver agreements on 3D TSE SPACE than 2D sequences for radial, root, and bucket handle tears.
Conclusion: At 3T MRI, the 3D PD fat-suppressed space turbo spin-echo (TSE) has higher diagnostic performance compared to the routine 2D TSE protocol for the detection of meniscal radial tears and similar results as regarding the other types of tears with the advantage of faster acquisition.

The utility of axial strain elastography in youth basketball players with a clinical diagnosis of patellar tendinopathy

R. E. A. Walker[1], O. B. A. Owoeye[2], Y. Chadha[3], J. P. Wiley[1], L. McLeod[1], T. Hubkarao[1], L. Palacios-Derflingher[1], C. A. Emery[1]; [1]*Calgary/CA,* [2]*St. Louis/US,* [3]*Toronto/CA (rewalker@ucalgary.ca)*

Purpose: To evaluate the diagnostic accuracy of axial strain elastography (ASE) for clinically diagnosed patellar tendinopathy (PTP) in youth basketball players.
Methods and materials: 52 participants (23 with PTP) were recruited from local youth basketball programs in 2016/17 and underwent sonographic assessment of bilateral patellar tendons, including ASE. Sonographers/sonologists were blinded to the case-control status of participants (PTP unilateral/PTP bilateral/no PTP). Images were partitioned, randomised, and archived for interpretation by two fellowship-trained musculoskeletal radiologists.
Using a graduated colour strain map (red-yellow-green-blue), two raters evaluated axial strain elastograms of the proximal patellar tendon and recorded tendons as 'soft'(>2/3 red), 'hard'(>2/3 blue), or 'intermediate' (neither 'hard' nor 'soft'). 'Soft' tendons were considered pathologic and cross-tabulated with clinically diagnosed PTP and controls to calculate accuracy, sensitivity, and specificity. The agreement was assessed between raters.
Results: 104 patellar tendons were scanned with ASE. 9 nondiagnostic exams were excluded, leaving 95 tendons for assessment. The inter-rater reliability was moderate (Kappa=0.491). The percent agreement was 76.8%. Of disagreements, 18/22 (81.8%) related to differences between classifying a tendon as 'soft' versus 'intermediate'. For reader 1, the accuracy of ASE compared to the clinical evaluation was 53% (42%-63%), sensitivity was 18% (7%-35%), and specificity was 71 (58%-82%). For reader 2, accuracy was 59% (48%-69%), sensitivity was 24% (11%-42%), and specificity was 77% (65%-87%).
Conclusion: ASE classification of tendons as 'soft', 'hard', or 'intermediate' stiffness had moderate inter-rater reliability. Further standardisation of definitions regarding ASE classification of tendons as 'normal' or 'pathologic' could improve inter-rater reliability.
As an isolated instrument, the accuracy of ASE for clinically diagnosed patellar tendopathy was poor.
Limitations: B-mode images visible on ASE elastograms could bias the reader.
Ethics committee approval: Local institutional ethics approval. Each participant provided written consent.

Femur lengthening via a retrograde approach with the motorised intramedullary lengthening nail: 10-year follow-up MRI results

R. Donners, A. H. Krieg, D. Harder; *Basel/CH (ricardo.donners@usb.ch)*

Purpose: To establish MRI findings of the knee after leg lengthening via a retrograde femoral approach by using a motorised intramedullary lengthening nail in comparison to the healthy contralateral knee.
Methods and materials: In this prospective self-controlled single-centre study, 13 patients were included. All received unilateral retrograde femoral lengthening with a motorised intramedullary nail (FITBONE®, Wittenstein intens GmbH, Igersheim, Germany) and the follow-up time was 10-12 years. MRI of the contralateral knee of each patient served as a control. Exclusion criteria were MRI-contraindications, previous contralateral knee surgery, or severe trauma.

Standard MSK 3T-MRI images were assessed for joint effusion, synovial proliferation, cartilage defects, fibrotic changes of Hoffa's fat pad, and quadriceps femoris muscle atrophy compared to the healthy contralateral knee. Cartilage defects were graded according to the ICRS-classification system. Patient demographics, range of motion, and pain were noted.
Results: 13/13 postoperative knees showed fibrosis of Hoffa's fat pad, 0/13 in the control group. Moderate to severe cartilage defects (grade II-IV) of the trochlear groove were found in 13/13 postoperative knees in the insertion area. 1 healthy knee showed mild trochlear cartilage defects (grade I). 6/13 postoperative knees showed retropatellar cartilage defects. 10/13 patients showed postoperative atrophy of the medial and lateral vastus muscle compared to the control side. No case showed signs of chronic synovitis or relevant amounts of joint effusion. All patients were pain-free and showed a full range of motion.
Conclusion: Retrograde femoral lengthening with a motorised intramedullary nail may be associated with femoropatellar cartilage defects, arthrofibrosis, and muscle atrophy. Without corresponding clinical impairment, these findings may be normal in long-term follow-up.
Limitations: A small cohort and no different surgical method for comparison.
Ethics committee approval: Ethics board approval and written patient consent obtained.
Funding: No funding was received for this work.

The role of shear-wave elastography in the diagnostic evaluation of plantar fasciitis

H. Y. Y. R, R. Chandra, D. K. Singh, N. Kumar, B. K. Nayak*; New Delhi/IN (harshith25yr@gmail.com)*

Purpose: To evaluate the added advantage of shear-wave elastography (SWE) over grey-scale sonography in the diagnosis of plantar fasciitis and to obtain a reproducible and reliable sonoelastographic shear stress cut-off value.
Methods and materials: In this prospective case-control study, 30 consenting patients having unilateral heel pain for >6 months and clinically diagnosed as unilateral heel pain were included. Patients were examined by the lead author and a faculty radiologist by B-mode sonography (for plantar fascia thickness), followed by SWE, obtaining a colour map for shear characteristics and quantitative data (shear velocity in cm/s and shear stress in kPa) using a 1x1 cm ROI placed at the position of the highest shear on the colour map. Sensitivity and false-positive rates with extrapolated specificity, PPV, and NPV were calculated, and shear stress cut-off values were obtained using the Chi-square test and ROC curve analysis. The unaffected foot from respective cases was taken as control (normal) for the study.
Results: Of 30 examined cases, mean thickness of plantar fascia was significantly higher (5.4 mm) in the affected foot compared to the unaffected (2.9 mm), with a standard ROC cut-off of 3.7 mm (sensitivity 93%, false-positive rate 10%). The mean shear stress in the plantar fascia on the affected side (60.1kPa) differed significantly from the unaffected side (150.7kPa). Taking 97.5kPa as the shear stress cut-off, considering affected patients having values below this cut-off, sensitivity was 81.8% and the false-positive rate was 10.6%. Extrapolated specificity, PPV, and NPV were 89.4%, 88.5%, and 83.1%. AUC was 0.91.
Conclusion: SWE shows superior diagnostic accuracy compared to grey-scale sonography in patients with plantar fasciitis and promises the potential for routine use in addition to B-mode US for the assessment of plantar fasciitis cases.
Limitations: A limited number of patients.
Ethics committee approval: Ethic committee approval obtained.

The prevalence of midtarsal (Chopart) sprains in the setting of acute ankle injury in professional soccer players

M. T. Leiderer, G. H. Welsch, I. Molwitz, M. L. Warncke, K.-J. J. Maas, P. Bannas, G. Adam, F. O. Henes*; Hamburg/DE (m.leiderer@uke.de)*

Purpose: To evaluate the prevalence of midtarsal joint injury and its association with ankle sprain in professional soccer players after acute ankle trauma.
Methods and materials: 48 ankle MRIs of 43 professional soccer players with acute trauma (all male; mean age 21 y; range 15-31 y), acquired from January 2012-September 2019, were enrolled in the study. 3 scans were performed on a 1.5 Tesla, the remaining 46 on a 3 Tesla scanner with a routine ankle MRI protocol. A retrospective review of all MR images was undertaken in consensus by two experienced musculoskeletal radiologists. Acute tear (complete and partial) of the ligaments of the midtarsal and the ankle joint was assessed. In particular, MR images were scrutinised for injury to the dorsal calcaneocuboid, bifurcate, short and long plantar, spring, and dorsal talonavicular ligaments.
Results: Overall there were 36 cases with an ankle sprain, 19 with deltoid, 27 with lateral collateral ligament injuries, and 7 with a syndesmosis injury. Acute midtarsal joint injury was present in 13 cases (27.1%). In 9 of these, the midtarsal injury was concomitant with an ankle sprain or syndesmosis injury. In total, there were 22 midtarsal ligamentous injuries including the calcaneocuboid (4 complete, 5 partial) and calcaneonavicular (3 complete, 1 partial) parts of the bifurcate ligament, the dorsal calcaneocuboid ligament (1 complete, 2 partial), and the dorsal talonavicular ligament (2 complete, 4 partial). The plantar ligaments and the spring ligament were intact in all cases.
Conclusion: A midtarsal sprain is commonly associated with an acute ankle injury in professional soccer players. Radiologists must ensure that midtarsal injuries do not remain unrecognised, as accurate diagnosis of midtarsal sprain in MRI is important for effective clinical management.

Tenosynovitis at the metatarsophalangeal joints: a feature of rheumatoid arthritis? Results from a large cross-sectional MRI and anatomical study of tendon sheaths of the forefoot

Y. J. Dakkak, F. Jansen, M. de Ruiter, M. Reijnierse, A. van der Helm-van Mil*; Leiden/NL (y.j.dakkak@lumc.nl)*

Purpose: Recent MRI-studies revealed that tenosynovitis in the hands is associated with rheumatoid arthritis (RA). Although the forefoot is a preferential location for RA-inflammation, it is unknown whether MRI-detected tenosynovitis at the metatarsophalangeal (MTP)-joints is associated with RA. Additionally, anatomic literature leaves it undetermined if tendons at MTP-joints are surrounded by a synovial sheath. These questions were investigated.
Methods and materials: 634 persons were included: 157 newly presenting RA-patients, 284 patients with other early arthritides, and 193 symptom-free persons. All underwent MRI of unilateral MTP (1-5)-joints. Images were scored by two independent readers for tenosynovitis, synovitis, and bone marrow oedema. Its association with RA was analysed using logistic regression. Macroscopically, 14 forefeet of donated bodies were examined at the flexor-tendons and extensor-tendons for the presence and course of tendon sheaths. Tissue surrounding tendons was injected with blue-dyed resin or silicon. The presence of a sheath was also studied by light-microscopy.
Results: MRI-detected tenosynovitis was associated with RA (OR 2.4 (95%CI 1.5-3.8, P<0.001) for flexor and OR 3.1 (95%CI 1.9-5.2, P<0.001) for extensor tendons). The sensitivity of tenosynovitis in RA was 42%. The specificity compared to other arthritides was 78% and compared to symptom-free persons 98%. Macroscopically, all extensor and flexor tendons crossing MTP-joints demonstrated clearly demarcated sheaths surrounding tendons. Microscopy revealed a synovial sheath at flexor and extensor tendons.
Conclusion: Flexor and extensor tendons at metatarsophalangeal-joints are surrounded by a tenosynovium. MRI-detected tenosynovitis at metatarsophalangeal-joints was associated with, and specific for, rheumatoid arthritis, both when compared to patients with other arthritides and healthy controls.
Limitations: Our study is cross-sectional; additional longitudinal studies on the diagnostic value are needed.
Ethics committee approval: Ethics committee approval obtained.
Funding: European Research Council and the Dutch Arthritis Foundation.

Effectiveness of ultrasound-guided treatment of plantar fasciitis: corticosteroid injection versus dry needling
A. Iozzelli, A. Cipriani*; Macerata/IT (aiozzelli@sirm.org)*

Purpose: To evaluate the efficacy and safety of ultrasound-guided treatment of plantar fasciitis using corticosteroid injection (CS) compared to the dry needling technique (DN).
Methods and materials: We enrolled 20 patients (12 females, 8 males, age 43.8±8.4 y) suffering from chronic plantar fasciitis, randomly allocated to the DN or the CS group. DN consisted of ultrasound-guided needling (18-gauge Chiba needle) of the plantar fascia calcaneal insertion with lidocaine 2%. The CS technique consisted of ultrasound-guided injection over the plantar fascia calcaneal insertion of 40mg/1ml triamcinolone acetonide with 1 ml lidocaine 2%. Evaluation of pain using the visual analogue scale (VAS, range 0-10) was obtained at baseline, 1 week, and 1, 6, and 12 months after the procedures. Morphology of plantar fascia and complications were recorded.
Results: The baseline VAS score was 8.19±1.2. CS resulted in superior pain reduction than DN at 1 week (1.50±1.35 vs 4.64±1.63, p=0.03) and 1 month (1.60±1.58 vs 3.73±1.35, p=0.04). Both techniques showed similar results at 6 months (2.50±1.18 vs 2.18±1.33, p>0.05) and DN resulted in better outcome at 12 months (DN=1.36±1.50 vs CS=4.00±2.45, p=0.03). The thickness of plantar fascia did not differ between the groups. No relevant complications were reported.
Conclusion: Our study demonstrates that DN could be an effective and safe option for the treatment of chronic plantar fasciitis, with better results in pain reduction than CS at 6 and 12 months follow-up. Conversely, CS gave immediate and short-term relief.
Limitations: The limited number of patients could affect the result of our study.
Ethics committee approval: Written informed consent was obtained from all patients.
Funding: No funding was received for this work.

RPS 1610-14 17:18
Quantitative 2D versus 3D geometric analysis on bones and joints in weight-bearing and non-weight-bearing cone-beam CT images
S. Berardo[1], M. Broos[2], J. G. G. Dobbe[2], M. Maas[2], G. J. Streekstra[2], R. H. H. Wellenberg[2]; *[1]Novara/IT, [2]Amsterdam/NL (berardo.sara@gmail.com)*

Purpose: The increasing use of cone-beam CT to diagnose ankle and foot problems urges the development of quantitative 3D analysis tools that deliver geometrical parameters corresponding to well-known 2D counterparts. We compared estimates of geometrical parameters from both cone-beam CT and radiographs as differences can be expected between 2D and 3D analyses.
Methods and materials: WB and non-WB cone-beam CT-images of the left and right hindfoot and forefoot were acquired on a Planmed verity cone-beam CT-scanner. Geometric analyses were performed on images of the foot in 2D using simulated radiography images and 3D using custom analysis software. Measurements included the calcaneal pitch, Meary's angle, the angle between 1st and 2nd metatarsal (MTT), the talocalcaneal angle, and cuboid height.
Results: 5 patients were included with a mean age of 39.6 years. All measurement results were statistically different in 2D and 3D (p<0.001). The average calcaneal pitch decreased in 2D and in both 3D WB compared to non-WB results. Meary's angle decreased in 2D measurements, however, increased using 3D measurements. The average angle between MTT1-2 increased in both approaches. During WB, the talocalcaneal angle decreased in both lateral-lateral and anterior-posterior 2D views and increased in 3D. Cuboid height decreased between non-WB and WB images by 1.3 and 6.5 mm in 2D and 3D images respectively (p<0.001).
Conclusion: The geometric parameters evaluated in 2D were different compared to 3D, which is likely caused by over-projection and the specific point of view. We expect that 3D measurement tools are more univocal and therefore more suitable for future use. Also, switching to 3D enables advanced analysis such as obtaining joint space maps.
Limitations: Sample-size, 2D and 3D comparisons, and multiple observers.

Establishing quantitative measures for detecting subtle calcaneonavicular coalition: a case-control study
S. Rajan, V. K. Venugopal, H. Mahajan, V. Mahajan, S. Gaur*; New Delhi/IN (drsriramrajan@gmail.com)*

Purpose: We propose to determine if calcaneonavicular distance measurement could differentiate between normal patients and subtle forme fruste of calcaneonavicular coalition.
Methods and materials: 77 consecutive subjects presenting with foot pain and referred for MRI were evaluated. We assessed the calcaneonavicular distance on axial T1 images, and the anterior process calcaneum (APC) and posterior extension of navicular on sagittal images. The presence or absence of calcaneonavicular coalition was assessed. 15 normal volunteers without foot pain were also assessed.
Results: In patients with an obvious coalition, the mean calcaneonavicular distance was 1.5 mm (+0.52), the mean length of APC was 9.99 mm (+ 1.7), and the extra-articular length of the navicular bone was 11.18 mm (+2.29). The corresponding measurements in patients with foot pain but no obvious coalition were 3.91 mm (+2.19), 9.9 mm (+1.11), and 11.97 mm (+2.77), and in the normal volunteers were 3.99 mm (+1.49), 10.93 mm (+1.63), and 12.55 mm (+1.2). A support vector machine classifier was trained to classify coalition using 77 patients and 15 normal volunteers with 5-fold cross-validation. Accuracies of about 88 % were achieved when these three measurements were employed. A principal component analysis estimated the variance explained at 43 %, 35%, and 22% for the 3 components, respectively, implying all 3 components have significant predictive value in classifying coalition.
Conclusion: The 3 measures described in this study can be reliably used to detect subtle calcaneonavicular coalition on MRI of the ankle joints.
Limitations: The small sample size for normal controls.
Ethics committee approval: IRB approval was obtained.

Comparison of hydrochloric acid infusion radiofrequency ablation with microwave ablation in an ex vivo liver model
H. Deng, T.-Q. Zhang, X. Jiang, J. Huang*; Guangzhou/CN (denghanx@sysucc.org.cn)*

Purpose: Normal saline infusion radiofrequency ablation (NSRFA) is a widely accepted treatment for tumours up to 3 cm in diameter. Microwave ablation (MWA) and hydrochloric acid infusion radiofrequency ablation (HRFA) may be better alternatives for larger tumours, but few studies comparing these 2 modalities have been published. Thus, this study is aiming to compare ablation zone sizes and shapes resulting from HRFA and MWA, using NSRFA as a control in an ex vivo bovine liver model.
Methods and materials: A total of 90 ablation procedures were performed prospectively, each using 3 modalities: NSRFA, HRFA, and MWA. For each modality, 5 ablation procedures were performed for each combination of power (80W, 100W, or 120W) and duration (5, 10, 20, 30, 45, or 60 minutes). Ablation zone outcome parameter includes transverse diameter (TD), longitudinal diameter (LD), volume (V), front distance (FD), and spherical ratio (SR).
Results: For ablation duration up to 30 minutes, the mean TD after HRFA and MWA did not differ significantly (β=0.13, *P*=.20). For ablation durations greater than 30 minutes, the mean TD was significantly larger after HRFA than after MWA (β=1.657, P<.001). The largest TD (9.46 cm) and the most spherical ablation zone (i.e. highest SR, 0.95) resulted from HRFA performed with 100W power for 60 minutes.
Conclusion: Both MWA and HRFA with power settings of 80W to 120W and a duration of 30 minutes are capable of treating tumours of 5 cm or less. For

tumours of 7 cm or larger, HRFA with power settings 100W and duration of 30 minutes or longer is a better option than MWA.
Limitations: THe ex vivo model is partly different from the clinical patient.

Review of the clinical effectiveness of PET-CT scans in the management of sub-solid pulmonary lesions at the Oxford Lung Cancer MDT in the last 5 years

M. Rinaldi[1], F. B. F. Botta[1], A. Di Gioia[1], A. Sykes[2], F. Gleeson[2], L. Srinivasan[2], D. Stavroulias[2], F. Di Chiara[2], N. Rahman[2]; [1]*L'Aquila/IT,* [2]*Oxford/UK (martabrinaldi@gmail.com)*

Purpose: The pre-operative assessment for lung cancer surgery includes a total body FDG PET/CT as a mandatory investigation for solid and sub-solid lesions. We sought to evaluate the clinical effectiveness of a PET-CT scan in the management of sub-solid nodules. We additionally assessed the relationship between SUVmax and nodule type.
Methods and materials: We retrospectively analysed 407 patients who underwent lung resections and received complete imaging work-up. A consultant radiologist confirmed the sub-solid nature of 94 lesions: 27 GGOs and 67 PSN. We then compared the histopathology results with CT and PET-CT.
Results: Comparing PET/CT staging to pathological staging, PET overstaged (p=0.013) a high proportion of patients with GGOs (42.9%) and PSN (19.4%), whereas the number understaged by PET were not significantly different (p=0.11).
Then, assessing PET/CT and CT concordance, we demonstrated that these investigations were never discordant with GGO and rarely (4.5%) in PSN (p=0.050).
Regression analysis assessed the correlation between SUVmax and nodule type, even when size was taken into account, and both size and nodule type were independent predictors of increasing SUVmax (p<0.001).
Conclusion: This study suggests that PET/CT rarely adds information for PSN and never for GGO compared with CT, whereas the relationship between SUVmax and nodule type revealed that GGO and PSN had significantly lower SUVmax than solid, suggesting a different behaviour of these lesions.
Thus, there is a strong argument for stopping PET for GGOs and careful consideration in PSN given the low likelihood of change from the CT findings. Further studies should test cost and clinical effectiveness of a PET/CT scan (£89,300 for this cohort of patients) in the management of sub-solid lesions.
Limitations: The retrospective assessment of data.

CT texture analysis in PET-negative lung cancer

J. Daffinà, D. Caruso, M. A. Tipaldi, M. Zerunian, T. Polidori, F. Pucciarelli, E. Ronconi, M. Rossi, A. Laghi*; Rome/IT (daffinajulia@gmail.com)*

Purpose: To differentiate benign from malignant lung nodules in PET-negative cases based on CT texture analysis (CTTA).
Methods and materials: We retrospectively analyzed 53 patients with lung nodules with a negative PET scan (standardised uptake value [SUV] <2.5) who underwent a CT-guided lung biopsy (CTLB). Based on the pathological report, the population was divided into two groups: malignant and benign lesions. A dedicated software (TexRAD) was used to segment target nodules, drawing a region of interest (ROI) for each CT slice which displayed the lesion. CT texture parameters, including kurtosis, standard deviation, mean, and skewness were extrapolated for each spatial scale image filtration (SSF) of texture parameters. P<0.05 was statistically significant. The receiver operating characteristic curve (ROC) was calculated considering as dependent variables each of the texture parameters and a dichotomous variable indicating the histological diagnosis (0=malignant, 1=benign) as independent.
Results: Kurtosis showed significant difference for each SSF (all P≤0.0013; SSF0 1.50±5,70 vs 0.99±4.22; SSF2 1.83±6.18 vs 0.30±3.06; SSF3 1.80±6.81 vs -0.09±1.91; SSF4 1.90± 5.38 vs 0.07±2.65; SSF5 1.3±3.77 vs 0.17±3.33; SSF6 0.88±2.5 vs 0.35±3.67) and was considered the best parameter to differentiate malignant from benign pulmonary nodules. The ROC analysis showed significant area under the curves (AUC) for kurtosis at SSF3 (P<0.001; AUC 0.654), skewness at SSF4 (P<0.001; AUC 0.642), and for standard deviation at SSF0 (P<0.001; AUC 0.821).
Conclusion: CTTA was useful in identifying significant features that can distinguish malignant from benign pulmonary lesions in cases without an altered glucose metabolism at the PET scan.
Limitations: The retrospective design.

MRI bias correction with an implicitly trained convolutional neural network

A. T. Simkó, T. Löfstedt, J. Jonsson, A. Garpebring, T. Nyholm*; Umeå/SE (attila.simko@umu.se)*

Purpose: Bias field correction deals with the intra-volume intensity inhomogeneities in magnetic resonance imaging (MRI) data. It has little significance for visual diagnosis yet it is a crucial step for the automation of radiotherapy solutions. Extensive research and evaluation show that the often used and well-established correction methods typically require parameter tuning for the given dataset or are expensive to compute.
Methods and materials: A novel method has been introduced, allowing for the training of a convolutional neural network (CNN) on non-medical images, making the model general and evaluating it for bias field correction on medical MRI data.
Results: The proposed method has been compared to an optimised N4ITK in three experiments. It produces nearly identical results to N4ITK for a benchmark test and similar results in a coefficient of variation, mean absolute error, mean error, and structural similarity for a BrainWeb-based experiment, with an average speedup factor of 137. Different methods performed best for the different investigated tissue types. It was also tested for real cases, often producing more radio realistic bias fields in the cases where N4ITK struggles. Also, no datasets were encountered where the method would not improve image quality.
Conclusion: Training a convolutional neural network implicitly, through the relation of the outputs of two similar training samples, is possible, omitting the need for true target data. The achieved model is not only generalised but also achieves comparable accuracy to N4ITK with a significant speedup.
Limitations: No numerical evaluation for real cases.

Pancreatic ductal adenocarcinoma: rim enhancement at CT imaging predicts histologic grade

M. Shantarevich, A. Egorkina, G. Karmazanovsky, E. V. Kondratyev, A. Kriger, A. Kurochkina, D. Kalinin*; Moscow/RU (shantarevichm@list.ru)*

Purpose: Survival rates and the prognosis of patients with pancreatic adenocarcinoma (PA) directly depends on the histologic grade of the tumour. The purpose of this study was to identify features and quantitative parameters at preoperative CT imaging for predicting the histologic grade of the tumour.
Methods and materials: 81 patients with histologically-verified pancreatic ductal adenocarcinoma (11 PA grade 1, 47 PA grade 2, and 23 PA grade 3) and preoperative CT imaging performed in the native, arterial, and portal phases (10 and 40 seconds since reaching the threshold density value on aorta), with the tube voltage 120 kV, were enrolled in this study. We compared mean absolute tumour and pancreatic parenchyma attenuation between groups for each contrast enhancement phase. For each patient, the presence of rim

enhancement was assessed and defined as irregular peripheral hyperdensity with a relatively hypodense central area on dynamic-enhanced images.
Results: The mean tumour density in the arterial phase was 51.1±17.6 HU, median 49 HU. The mean tumour density in the venous phase was 63.0±18.9 HU, median 63 HU. Among PA grade 1, in 81.8% the rim enhancement was not observed. PA grade 2 was found in 85.71% cases where it was impossible to unequivocally speak out in favour of the absence or presence of the rim enhancement. In the presence of the rim enhancement in 96.42%, PA was grade 2 or grade 3. The density of PA grade 1 in 90.91% was <63 HU and the density of PA grade 3 in 69.57% was ≥63 HU.
Conclusion: Rim enhancement of PA was associated with more aggressive histologic tumour grades.

Determinants of ADC in the bone marrow of healthy individuals: effects of sex, age, and fat fraction

L. Bombelli[1], A. Colombo[1], G. Signorelli[1], A. Rossi[2], P. Summers[1], R. Grimm[3], M. Bellomi[1], G. Petralia[1]; [1]Milan/IT, [2]Meldola/IT, [3]Erlangen/DE
(bombelli.luca@virgilio.it)

Purpose: In literature, there is little documentation of ADC values in normal bone marrow and of the effects of physiological factors. The aim of this study is to evaluate how sex, age, and fat (evaluated from %FF) affect the ADC values measured in the bone marrow of healthy individuals.
Methods and materials: We processed the diffusion-weighted images of WB-MRI examinations in 100 asymptomatic individuals, 50 men and 50 women aged 30-79 years. The mean value of ADC in bone marrow (ADCbm) was estimated by fitting the histogram extracted from the images with a semi-automatic segmentation technique. The %FF value was measured as the average of ROIs drawn in specific positions (iliac bone, D10, L4). Gender differences were assessed with the Mann-Whitney U test, while ADCbm correlations with age and %FF were assessed with the Spearman correlation coefficient (ρ).
Results: The values of ADCbm were significantly higher in women than in men (respectively 458.1±63.3 $\mu m^2/s$ and 383.0±58.4 $\mu m^2/s$, $p<0.01$). A significant negative correlation of ADCbm with age ($\rho=-0.46$, $p< 0,001$) was observed in women but was absent in men ($\rho=-0.04$, $p=0.79$). Moreover, there was a negative correlation between ADCbm and %FF in both women and men (respectively: $\rho=-0.52$, $p<0.001$ and $\rho=-0.28$, $p<0.05$).
Conclusion: There was a significant difference between ADCbm values of men and women. The negative correlation between ADCbm and age in women is likely related to menopause, while that between ADCbm and %FF, present in both sexes, appears to be a separate process.
Limitations: Calculate ADCbm and %FF with two different approaches.

Radiomics signature of the human papillomavirus (HPV) status in oropharyngeal squamous cell carcinoma (OPSCC)

S. P. Haider[1], A. Mahajan[1], T. Zeevi[1], P. Baumeister[2], C. Reichel[2], K. Sharaf[2], B. Judson[1], B. Burtness[1], S. Payabvash[1]; [1]New Haven/US, [2]Munich/DE
(stefan.haider.mdf@gmail.com)

Purpose: HPV-positive and HPV-negative forms of OPSCC are biologically distinct entities, with different prognosis, treatment strategies, and divergent AJCC/UICC staging schemes. Using feature selection and machine-learning classification algorithms, we identified the radiomics signature of HPV on pre-treatment FDG-PET and non-contrast CT scans.
Methods and materials: All data was retrieved from the Cancer Imaging Archive. Patients with OPSCC, known HPV-status, and pre-treatment PET/CT were included. The primary tumour and metastatic cervical nodes were separately segmented on PET scans; segmentations were then copied and adapted to the coregistered CT. A set of 1,040 radiomics features was extracted from each segmentation and per imaging modality.
To predict HPV-status, minimum-redundancy-maximum-relevance (MRMR) feature selection and random forest (RF) machine learning classifiers were applied in 5-fold cross-validation, repeated x10. The area-under-the-curve of receiver-operating-characteristic-curves (AUC-of-ROC) averaged across validation folds is reported.
Results: Of 114 included OPSCC cases, 87 had HPV-positive and 27 had HPV-negative forms. In addition to primary tumour lesions, 119 HPV-positive and 51 HPV-negative metastatic cervical nodes were analysed.
The primary tumour RF models achieved an averaged AUC-of-ROC of 0.69 (PET), 0.75 (CT), and 0.73 (PET/CT), based on 20 features selected by MRMR from the respective feature sets. In comparison, the averaged AUC of lymph node RF models was 0.66 (PET) and 0.64 (CT), based on 20 MRMR-features. PET-based lymph node models were non-predictive.
Conclusion: Radiomics feature extraction from FDG-PET and non-contrast CT scans, combined with machine learning classifiers, can generate imaging biomarkers for HPV-status in OPSCC primary tumours and metastatic lymph nodes, which may aid pathologists in HPV-classification if standard immunohistochemical staining is equivocal or supplement the immunohistochemical tests in subjects requiring second-line testing.

Repeatability of quantitative WB-MRI analysis in patients with bone metastases

G. Saia[1], A. Colombo[1], A. Rossi[2], A. Azzena[1], F. Zugni[1], P. Summers[1], R. Grimm[3], M. Bellomi[1], G. Petralia[1]; [1]Milan/IT, [2]Meldola/IT, [3]Erlangen/DE
(giulia.saia.gs@gmail.com)

Purpose: WB-MRI is increasingly recommended for the evaluation of patients with metastatic bone diseases. A semi-automatic technique for the segmentation of diffusion-weighted images in WB-MRI examination has been developed to allow quantitative evaluation of tumour burden in bone metastases. The aim of this study was to evaluate the intra and interobserver repeatability of quantitative analysis of ADC in healthy and metastatic bone marrow in patients with bone metastases from breast cancer (BCa) and prostate cancer (PCa).
Methods and materials: 4 independent observers processed WB-MRI examinations from 20 patients with bone metastases (10 women with BCa and 10 men with PCa). Segmentation of bone marrow was performed applying a threshold on high b-value diffusion-weighted images and manually removing misclassified non-bone regions. The total volume of bone marrow (V_{bm}) and first-order ADC statistics were then obtained. We measured repeatability using intraclass correlation coefficients (ICC) and Bland-Altman method.
Results: We observed good to excellent ICC values in 4 parameters: ADC_Mean with intra and interobserver ICCs respectively of 0.92 (0.85-0.96, CI 95%) and 0.85 (0.75-0.92), ADC_Median 0.92 (0.85-0.96) and 0.88 (0.79-0.93), ADC_5% 0.9 (0.81-0.94) and 0.8 (0.69-0.88), and ADC_Skewness 0.9 (0.80-0.94) and 0.86 (0.76-0.92). Bland-Altman bias and limits of agreement calculated for ADC_Mean were, respectively, -1.1% and -13.7%–12.1%, and 5.0% and -18.8%–15.3% in intra and interobserver analysis. Repeatability was higher in BCa patients than in PCa patients.
Conclusion: While bias was almost 5 times greater for interobserver relative to intra, the limits of agreement were increased by only about 25%.
Limitations: Difficulties in segmenting PCa patients data likely led to lower repeatability in these patients relative to BCa patients.
Ethics committee approval: Approved by internal review board.

Thermal ablation of central renal tumours performed with a retrograde cold pyeloperfusion technique

G. Mauri[1], D. Rossi[2], G. Bonomo[1], P. della Vigna[1], D. Maiettini[3], G. M. Varano[4], L. Mascagni[4], F. Orsi[1]; *[1]Milan/IT, [2]San Donato Milanese/IT, [3]Perugia/IT, [4]Rome/IT (duccio.rossi@unimi.it)*

Purpose: To assess treatment safety and efficacy following thermal ablation of centrally located renal tumours performed with retrograde pyeloperfusion.
Methods and materials: From November 2011-December 2018, 54 patients (17 females, 37 males, mean age 69, range 41-89) underwent 64 renal ablations for centrally located renal tumours, 58/64 (90.6%) renal cell carcinomas (RCC), 5/64 (8%) oncocytomas, and one metastasis. Inclusion criteria consisted of biopsy-proven renal masses <4 cm (T1a); the average lesion size was 32.5 mm (range 16-67 mm). 7 mono-renal patients underwent 13/64 (13%) procedures. Microwave (MWA), radiofrequency (RFA), or their combination were the ablation techniques of choice, 33/64 RFA (52%), 29/64 (45%) MWA, and 2/64 (3%) MWA+RFA. All treatments were performed with ultrasound- and CT-guidance under general anaesthesia and a simultaneous retrograde cold pyeloperfusion technique in a dedicated angiography room setting.
Results: The primary technical success overall was reached in 57/64 cases (89%). Primary technical efficacy at 1 month overall was reached in 48/64 (75%) lesions. 12 lesions underwent a second treatment, with a secondary efficacy of 54/64 (84%). 2/54 (4%) underwent nephrectomy. At a median follow-up of 26.5 months, 3/54 patients died of unrelated events. The mean procedure duration overall was 32 minutes (range 2-160 minutes). Adverse events (AEs) were reported in 15/64 lesions (23%), 5/64 (8%) major AEs and 10/64 (16%) minor AEs.
Conclusion: Percutaneous thermal ablation of central renal tumours associated with protective pyeloperfusion is a safe and effective treatment option allowing for kidney function preservation and radical results in a large majority of cases. This technique can be useful for avoiding nephrectomy in mono-renal patients.
Limitations: The retrospective nature of the study.
Ethics committee approval: The protocol was approved by the ethics committee.

A minimally-invasive approach to symptomatic uterine fibroids: fibroids location as a predictor of treatment efficacy

P. Palumbo, A. Iacopino, A. V. Giordano, M. Di Luzio, S. Carducci, M. Varrassi, S. Mascaretti[3], G. Mascaretti, C. Masciocchi; *L'Aquila/IT (palumbopierpaolo89@gmail.com)*

Purpose: To retrospectively evaluate the comparing efficacy of MRgFUS and UAE in the treatment of different location-type uterine fibroids.
Methods and materials: 71 women consecutively treated for symptomatic uterine fibroids were enrolled in our study. Primary (clinical) and secondary (imaging efficacy evaluation) outcomes were evaluated. Pre-procedural and 1-year post-treatment MRI examinations were analysed.
Results: 27 patients were treated by UAE. The overall success rate was 94.63%. The response rate was 100% in submucosal groups and 87.5% and 72.73% in intramural and transmural groups, respectively. A significant difference was observed between transmural and both submucosal and intramural post-treatment severity scores (p=0.006 and 0.017, respectively), while no differences were observed between submucosal and intramural groups (p=0.33). No difference was found between the three groups in the Kaplan-Meier analysis (Log-rank: p= .74). 44 patients were treated with MRgFUS. The overall success rate was 83.01%. Notably, RR was 66.67% in the submucosal group, and 64.71% and 55.56% in intramural and transmural groups, respectively. A significant difference was observed between transmural and both submucosal and intramural post-treatment scores (p=0.016 and 0.017, respectively), while no differences were observed between submucosal and intramural groups (p=0.637). A significant difference was found between the three groups according to the Kaplan-Meier analysis (Log-rank: p=0.001).
Conclusion: MRgFUS and UAE are highly effective techniques in the treatment of symptomatic uterine fibroids. Fibroid type analysis should be considered for adequate treatment planning, especially for FUS treatment, which finds the primary indication for submucosal fibroids.
Limitations: The single-centre analysis and the retrospective analysis.
Ethics committee approval: Our study was conducted in accordance with the declaration of Helsinki.

CT-guided biopsy of the adrenal gland in patients suspected of lung cancer

C. Lückerath, B. Högerle, P. Flechsig, E. Herpel, M. Eichhorn, H. Winter, H.-U. Kauczor, C. P. Heußel, G. Heußel; *Heidelberg/DE (christian.lueckerath@med.uni-heidelberg.de)*

Purpose: To confirm adrenal metastasis of suspected lung cancer and for molecular tumour characterisation, a biopsy is required. CT-guided biopsy offers 3D visualisation of adjacent anatomical structures in real-time and a detection of complications.
Methods and materials: A retrospective analysis of all CT-guided biopsies of the adrenal glands performed from 2016-2018 at Thoraxklinik Heidelberg to evaluate outcome and complications and to identify potential risk factors.
Results: 53 CT-guided biopsies were performed in 50 patients (24 left/29 right). No transrenal, transsplenic, transpancreatic, or transpulmonal path was chosen. Anticoagulation was paused according to the guidelines in 16/22 cases. No major complications like death, abscess, pneumothorax, or Hb-relevant bleeding occurred. In 22 patients, a small local haematoma with a median size of 6 ml without further treatment was observed. 20 patients reported pain within the first hours after the intervention, which was easily treated with metamizole. 1 of those 15 patients with a transhepatic pathway showed an incidental arterioportal fistula in a follow-up CT, which did not require further action. The intervention duration from local anaesthesia to the control scan was a median 16 minutes, with a range of 7-35 minutes, and was well tolerated by the patients. Malignancy was confirmed in 92%. In 2 cases, an adenoma was detected; one lesion showed high FDG-uptake and the other high density on CT. In 2 cases, a definite determination was not possible.
Conclusion: CT-guided biopsy of the adrenal gland is a safe, fast, and reliable method to verify and characterise metastases in patients suspected of lung cancer. Pathways, patient positioning, investigator experience, and procedural manoeuvres are essential and will be communicated.
Limitations: A relatively small number of procedures.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

Application of a novel image-processing method: digital variance angiography (DVA) in prostatic artery embolisation (PAE)
L. S. Alizadeh[1], T. J. Vogl[1], J. Kiss[2]; [1]*Frankfurt am Main/DE,* [2]*Budapest/HU (leona.alizadeh@outlook.de)*

Purpose: To compare the performance of digital variance angiography (DVA) versus conventional digital subtraction angiography (DSA) for its utility in image-guidance during prostatic artery embolisation (PAE) of benign prostatic hyperplasia. DVA is a novel x-ray image processing algorithm for the visualisation of contrast motion.
Methods and materials: We evaluated angiographic acquisitions of 15 patients (mean age 67.47, SD 9.76, range 42-82) undergoing PAE at our institution. For quantitative image-quality comparison, signal-to-noise ratio (SNR) of DSA and DVA image pairs were compared using multiple regions of interest (ROI) for each image. Qualitative image-quality evaluation was done in a randomised blinded trial by three experienced interventional radiologists using clinically relevant criteria (e.g. visibility of feeding- and collateral-branches, size of examinable arteries, and detectability of the prostatic artery). Fleiss' kappa-test was used to determine interrater agreement.
Results: DVA images provided 1.79 times higher SNR than DSA (median value, Q1-Q3 interval was 1.46-2-32). The visual evaluation indicated that DVA provided higher quality images than DSA since 90.6% of comparison evaluators preferred DVA over DSA images. The inter-rater agreement was 93.8% and Fleiss's kappa was 0.38 ($p<0.01$).
Conclusion: In PAE, DVA-imaging enhances the visualisation of anatomical structures compared to DSA-imaging via significant SNR reduction. The new technology might improve the safety and efficacy of the intervention. As an additional advantage, the observed quality reserve of DVA might also reduce the radiation dose and the amount of contrast agent.
Limitations: A retrospective trial. Aspects of workflow, radiation-dose, and intervention time have to be investigated in an upcoming prospective trial comparing DVA versus DSA directly in the intervention room.
Ethics committee approval: This study was approved by our institutional ethics board.
Funding: No funding was received for this work.

Uterine fibroid embolisation efficacy and safety: 15 years experience in an elevated turnout rate centre
A. Paladini[1], I. Percivale[1], M. Spinetta[1], S. Bor[2], D. Negroni[1], M. Cernigliaro[1], A. Borzelli[3], F. Pane[3], G. F. Buoni[4]; [1]*Novara/IT,* [2]*Santhià/IT,* [3]*Naples/IT,* [4]*Turin/IT (20027467@studenti.uniupo.it)*

Purpose: To evaluate the effectiveness and safety of UFE as an alternative to surgery in the treatment of uterine fibromatosis.
Methods and materials: 255 patients (aged 26-55) with symptomatic UF, indicated for surgery, followed in our centre (2000-2014), with single or multiple fibroids, and pain and/or functional/compressive disorders underwent embolisation; an injection of PVA particles (150-900 µm) from the distal portion of uterine arteries (ascending section). The primary end-point was a flow-stop distally to the injection site, disappearance of the lesion design, and the preservation of flow in the main trunk of UA. The secondary end-point was the control of pain and functional/compressive disorders during follow-up (2-7 years).
Results: The procedure was performed bilaterally in 250 patients (98%). The mean duration was 47 min (average fluoroscopy: 10-50 min).
Post-embolisation pelvic pain (according to a VAS score) was on average 2.2 at discharge (24h). Follow-up at 2 years showed a resolution of menstrual disorders in 78% of patients and improvement in 14%, pain disappeared in 66%, significant improvement of menstrual flow and HCT/HB levels, and adecrease in total uterine (57.7%)/dominant fibroid (76.1%) volume. There was recurrence in 18 patients.
Conclusion: UFE represents an excellent alternative to surgical treatment. It is safe, tolerable, and effective both in the short and long term, with evident advantages in economic and social terms.
Limitations: A retrospective study without randomisation.

The great migration: predicting intramural uterine fibroid migration after uterine artery embolisation
E. Y. Auyoung[1], L. A. Ratnam[2], R. Das[2], S. M. M. M. Ameli Renani[2], L. Mailli[2]; [1]*Basingstoke/UK,* [2]*London/UK (e.auyoung@doctors.org.uk)*

Purpose: To analyse pre-UAE MR images with a view to predicting migration of intramural fibroids post-UAE to better advise patients of the procedural risks.
Methods and materials: We retrospectively reviewed all patients referred for UAE for symptomatic fibroids at our institution over one year. Patients without a pre-procedural MRI and a six-month post-procedural MRI were excluded from the study. Both pre- and post-UAE images were independently reviewed by two radiologists with subsequent consensus review. In each, dominant intramural fibroids were identified and the following measurements taken: a) 3-dimensional maximal measurements, b) the shortest distance between the fibroid and the endometrial wall, and c) the shortest distance between the fibroid and the serosal wall. Paired sample t-tests and two-sample t-tests were used to compare between pre- and post-UAE variations and between migrated and non-migrated intramural fibroids, respectively.
Results: 35 dominant intramural fibroids were identified, of which, 8 migrated to become submucosal fibroids, while 5 were either partially or completely expelled. All migrating fibroids had a pre-UAE minimum distance from the endometrium of 1-2.4 mm and a maximum fibroid diameter greater than 5.1 cm, and none of the non-migrating fibroids had both these characteristics together.
Conclusion: Not only is it distressing to patients to have post-procedural pain and bleeding, but fibroid migration could also increase infection risks and affect fertility. Our study found that intramural fibroids with a minimum endometrial distance less than 2.4 mm and a maximum fibroid diameter greater than 5.1 cm have a high likelihood of migrating after UAE.
Limitations: Small sample size and low statistical power.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Investigating the clinical value of colour-coded pelvic parametric x-ray angiography for image guidance in prostatic artery embolisation for benign prostatic hyperplasia
L. S. Alizadeh, T. J. Vogl, A. Zinn; *Frankfurt am Main/DE (leona.alizadeh@outlook.de)*

Purpose: A major challenge in prostatic artery embolisation (PAE) is an adequate and distinct visualisation of the feeding prostatic vessels and other branches of the internal iliac arteries. Novel colour-coded parametric images calculated from raw angiographic image data provide additional information compared to common digital subtraction angiography (DSA). Our objective was to investigate the clinical value of parametric images in a PAE setting.
Methods and materials: We retrospectively examined the selective internal iliac artery image series of 26 patients (mean age: 67.47; SD: 9.76; range: 42-82) undergoing PAE. We generated 230, parametric, colour-coded-delay-angiograms (CDAs) from raw image data obtained from a latest-generation angiography system. Three experienced interventional radiologists evaluated the image quality using a 5-point-Likert scale based on clinically relevant criteria (e.g. the identification of dominant feeding arteries, stenoses, and non-target collaterals).

Results: Subjective image quality was evaluated with mean scores of 4.16 (range 3-5; std.deviat.+-0.73), significantly higher for DA compared to the mean scores of 3.43 (range 2-5; std.deviat.+-1.80) for standard DSA. Evaluators agreed CDAs provided more information than the simple BW angiograms (87%), the image would be useful to select the dominant feeding artery (93%), and the functional stenoses of the branches could also be determined (84%). The inter-rater agreement, Fleiss' kappa, and significance were 81%, 0.19, $p<0.05$, 85%, 0.32, $p<0.01$, and 79%, 0.11, $p<0.05$, respectively.
Conclusion: Parametric delay images calculated from x-ray angiography series provide more information than standard angiograms and hold additional information about the branches of the internal iliac artery. Decision-making based solely on CDAs will require an appropriate prospective safety assessment.
Limitations: Colour-coded-parametric-angiography has to be tested in upcoming prospective trials to prove our results for real-time image guidance.
Ethics committee approval: University hospital ethics committee approval obtained.
Funding: No funding was received for this work.

Which women affected by uterine fibroids can be selected for MRgFUS treatment? Our experience

I. Capretti, L. P. Vazzana, S. Iafrate, E. Cannizzaro, F. Arrigoni, M. Di Luzio, S. Mascaretti, G. Mascaretti, C. Masciocchi*; L'Aquila/IT (luciavazzana@gmail.com)*

Purpose: To demonstrate that a careful selection of patients is important to predict the execution of treatment and a good result.
Methods and materials: 228 women with uterine fibroids were submitted to c.e. MRI to evaluate the possibility of MRgFUS treatment. The ablation results were evaluated by the non-perfused volume (NPV) on contrast-enhanced MR images acquired after the treatment.
Results: 115 women out of 228 (50.4%) were considered suitable for treatment (good MRI features of the dominant fibroids and adequate acoustic window); 15 of them obtained an incomplete result and other treatments (a second MRgFUS, uterine artery embolisation (UAE), or surgery). The mean value of the NPV ratio was 67.4%, assessed immediately after the treatment. 113 patients out of 228 were not eligible for the treatment: 8/113 women had an abdominal scar, 39/113 patients showed interposition bowel, reverse uterine position, or inadequate acoustic window, and 66/113 had inappropriate features of the fibroids such as number, side (i.e. pedunculate position), big size, or high vascularisation.
Conclusion: MRgFUS is a mini-invasive treatment and it is well tolerated by patients. A correct selection is necessary to achieve a risk-free treatment and good clinical results.
Limitations: The radiological evaluation according to criteria in the literature for the MRgFUS treatment.
Ethics committee approval: n/a

Results after endovascular uterine artery embolisation in the treatment of symptomatic leiomyoma

D. Tazhibaev, B. Abishev*; Nur-Sultan/KZ (tazhibaev74@mail.ru)*

Purpose: To evaluate fibroid size using ultrasonography (US) and magnetic resonance imaging (MRI) after uterine artery embolisation (UAE) of leiomyoma.
Methods and materials: 1,023 women with symptomatic leiomyoma were treated by bilateral transcatheter UAE. Angiography and embolisation were performed using 5F Cobra and Roberts uterine catheters by 355-1,000µm of PVA particles. The size of particles depended on the uterine artery diameter and anastomosis between the uterine and ovary arteries. The mean age was 29.5 years (range: 19-47).
Results: The moderate reduction of leiomyoma size was observed one month after UAE. The reduction of fibroid size after 1 month was 18.4% by US and 17.3% by MRI, after 3 months was 40.7% by US and 42.9% by MRI, after 6 months was 60.4% by US and 61.8% by MRI, after 12 months was 72.5% by US and 74.7% by MRI, and after 24 months was 70.8% by US and 72.2% by MRI. Doppler US-control showed a blood flow decrease during the first month after UAE; in 3 months, blood flow data was restored in uterine arteries. We also noticed a significant reduction or disappearance of clinical symptoms such as pain, menorrhagia, and pressure symptoms. The partial vascularisation of leiomyoma was only detected in one case 24 months after UAE.
Conclusion: UAE is an effective, minimal-invasive form of leiomyoma treatment. MRI and US are the modalities that can accurately estimate fibroid changes and blood flow in uterine arteries. The tendency of fibroid shrinkage after UAE is well-defined in the period from 1-24 months. After UAE, the blood supply of myometrium is restored according to US Doppler data in the period from 1-3 months.

Melting time analysis of radiographic ice-balls during thawing in renal cryoablation: a proposal for the optimal time of cryoprobe removal

M. J. Kim, S. Y. Park*; Seoul/KR (minje1107.kim@samsung.com)*

Purpose: Cryoprobe removal before sufficient thawing may lead to tissue injury and bleeding. We analysed the melting time of radiographic ice-balls during thawing in renal cryoablation by using ultrasound (US) examination.
Methods and materials: A consecutive 27 patients who underwent percutaneous cryoablation with cryoprobes of 2-4 for a renal tumour (median size, 1.9 cm; range, 1.1-4.1 cm) were evaluated. Reconstructed CT images obtained during freezing were used to measure the radiographic ice-ball volume. After completing a last freezing, the melting time of the radiographic ice-ball was analysed with US. The melting time was defined as the time of complete disappearance of intrarenal posterior acoustic shadowing generated by a radiographic ice-ball, which was analysed by two independent radiologists. After removing the cryoprobes, the degree of perirenal haematoma was assessed (i.e. <1 cm versus ≥1 cm in thickness). Serum haemoglobin (Hb) was also investigated before and after cryoablation.
Results: The median radiographic ice-ball volume was 30.3 cm^3 (range, 21.0-62.8 cm^3). The median melting time of radiographic ice-balls on US was 13 and 14 minutes for radiologist 1 and 2 (range, 9-15 minutes for both radiologists) ($p>0.05$). A positive correlation was found between melting time and radiographic ice-ball volume (Spearman's rho, 0.647 and 0.484 for radiologist 1 and 2). Perirenal haematomas of ≥1cm in thickness were seen in two patients (7.4%). No patient required treatment for the bleeding. The median decrease of serum Hb was 0.3 g/dl.
Conclusion: Ice-balls of renal cryoablation may require 15 minutes for complete melting, which may be considered as the optimal time for cryoprobe removal.
Limitations: A small, single-institution study.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Pregnancy results: favourable outcomes and fertility perspectives in women treated by MRgFUS for uterine fibroids

L. P. Vazzana, I. Capretti, S. Iafrate, F. Arrigoni, M. Di Luzio, S. Mascaretti, G. Mascaretti, C. Masciocchi*; L'Aquila/IT (luciavazzana@gmail.com)*

Purpose: To discuss fertility perspectives in women treated by MRgFUS and to report pregnancy after this procedure.
Methods and materials: 15 patients aged between 26 and 47 (mean age 36.4) affected by uterine fibroids who wanted to get pregnant were treated in our department with MRgFUS. This study evaluated the findings of 15 patients presenting with a difficulty to conceive and uterine fibroids smaller than 5.5 cm. We preliminarily excluded the other causes of infertility with a gynaecological evaluation. All patients had only one treatment. We made a c.e. MRI in order to control the non-perfused-volume immediately after treatment and then after 3, 6, and 12 months from the procedure.
Results: After 12 months from the treatment, 11 patients had complete reabsorption of the necrotic areas and 4 had partial reabsorption. 7 months later, the patients started the course to become spontaneously pregnant. 3 succeeded and 1 has already given birth at term to a healthy infant without any perinatal complications. Another patient with partial reabsorption of the necrotic area gave birth to a baby and another is now in her seventh month of pregnancy.

Conclusion: MRgFUS permits a significant reduction of the clinical symptomatology and is a valid alternative method to surgery in fertile women, without any complications in case of uterine implanting.
Limitations: A small group of patients.
Ethics committee approval: n/a

Percutaneous thermal ablation of small renal tumours: a singe-centre experience

G. Dar, N. Goldberg, A. Lorber, L. Appelbaum*; Jerusalem/IL*
(gili.dar@mail.huji.ac.il)

Purpose: Percutaneous ablation has been proven as a safe and effective treatment for small renal tumours. The treatment has been available in Israel for over 15 years. We will present the results of a single-centre experience, the largest ablation service in Israel.
Methods and materials: A retrospective study of 199 percutaneous renal tumour ablations was conducted. All patients (mean age 68 (±12); 53/146 female/male) were treated using ablation (microwave ablation 42%, radiofrequency ablation 50%, and cryoablation 8%) during 2013-2019. The average tumour diameter was 25 mm (10-58 mm); 104 tumors were exophytic, 69 were endophytic, and 26 were mixed. In 85 of the cases (42%), a biopsy was performed prior to the ablation. The pathological report revealed that 38 (44%) were clear-cell RCC, 10 (12%) were papillary type RCC, 2 (2%) chromophobe type RCC, 12 (14%) oncocytic tumour, 14 (16%) non-diagnostic, and 9 (12%) other. The monitoring protocol after treatment included imaging after 1, 3, 6, and 12 months subsequent to treatment and later annually; the median follow-up time was 26 months (1-122).
Results: Evidence of tumour recurrence was observed in 25 patients (12.6%); 13 were treated successfully by another ablation session. Cases in which recurrence was observed were characterized by a tumour larger than 30 mm (10-56). 10 of the lesions were central (endophytic).
Conclusion: Percutaneous ablation is a safe and effective treatment for small renal tumours. 89% of long-term complete ablation may be reached. In cases of remnant tumour tissue or recurrence, ablation can be repeated with good results.
Limitations: A single-centre study.
Ethics committee approval: In process.

Clinical and economic impact of transperineal laser ablation (TPLA) for treating focal unilateral prostate cancer

G. Manenti[1], T. Perretta[1], S. Marsico[1], C. P. Ryan[1], D. D'amato[1], M. Martins-Favre[2], S. Regusci[2]*; [1]Rome/IT, [2]Geneva/CH*

Purpose: To evaluate the therapeutic success, complications, and economic impact of transperineal US-guided focal laser ablation by US/MRI fusion software as a primary treatment for focal unilateral prostate cancer.
Methods and materials: 24 patients with newly diagnosed, histopathologically-proven, focal unilateral prostate cancer were treated with US-guided transperineal focal laser ablation as a primary treatment. The inclusion criteria were no previous prostate treatment, a PSA level ≤20, a Gleason score ≤7, and stage ≤ T2b N0M0 with 3T multi-parametric MRI-visible index lesion (PIRADS ≥ 4). After the ablation, a 3T mpMRI of the prostate was obtained. Follow-up consisted of mpMRI at 1, 3, 6, and 12 months and a US/MRI fusion-guided biopsy at 6 and 12 months.
Results: 24 patients were successfully treated with transperineal US-guided focal laser ablation. No complications occurred. The IPSS and SHIM did not significantly change after treatment. The mean operation time was 38.2 minutes (range 32.6-42.5), the mean ablation time was 21.7 minutes (range 18.3-26.8), the mean energy deployed was 3606J (range 3212-3804), the mean hospital stay was 113 minutes (range 55-178), and the mean catheterisation time was 261 minutes (range 95-412). At the 6- and 12-month follow-up, prostate mpMRI and US/MRI fusion-guided biopsy showed neither evidence of local residual disease nor recurrence.
Conclusion: Transperineal US-guided focal laser ablation as a primary treatment for prostate cancer has shown encouraging results. Ten-year follow-up with an international registry is intended to confirm oncological long-term prostate cancer with index lesion control.
Limitations: A small number of treated patients, short follow-up, and our first experience with this technique.

Decision-making between radiofrequency and cryoablation based on tumour size, central location, and nearness to the collecting system for the management of cT1 RCC: a comparative study of 408 patients

T. Ramtohul[1], A. Méjean[1], M.-O. Timsit[1], C. Delavaud[2], J.-B. Quere[1], O. Helenon[1], J.-M. Correas[1]*; [1]Paris/FR, [2]Houilles/FR*
(toulsie@me.com)

Purpose: To evaluate our decision-making between RFA and CA based on tumour size, central position, and nearness to the collecting system on technical efficacy and oncologic outcomes for cT1 RCC.
Methods and materials: All cT1 RCC from 2005-2019 were included. Patients treated before 2013 were included in the RFA group and patients treated after 2013 were included in the CA or RFA group, where CA was performed for large (≧35 mm) central tumours or RCC with a nearness to the collecting system, while RFA was performed for smaller (<35 mm) and non-central RCC. The IPTW based on clinical and tumour features was applied. The primary success was compared using logistic regression, while local recurrence-free survival was compared using Cox proportional hazards regression. Clavien complications and the change in renal function (MDRD) were also evaluated.
Results: Data from 408 patients were analysed. The primary success rate was higher in the CA or RFA group compared to the RFA group (97.1% vs 87.1%, p<0.001). Local recurrence-free survival was better in the CA or RFA group compared to the RFA group (HR=0.49; 95%CI: 0.28-0.84; p=0.01). Survival without metastases was not different (p=0.65). The incidence of Clavien grade ≥2 adverse events (p=0.30) and the change of renal function (p=0.35) was similar.
Conclusion: Our decision-making between CA and RFA achieved a better primary success rate and local recurrence-free survival compared to RFA alone, with excellent oncologic outcomes for RFA in selected patients and also for large and central RCC mainly treated with CA.
Limitations: The retrospective design.
Ethics committee approval: Institutional review board approval was obtained to review the medical records of patients who underwent ablation of RCC at Necker University Hospital.

Adrenal glands haemorrhages: embolisation in an acute setting

F. Giurazza, F. Corvino, F. Pane, M. Silvestre, M. Coppola, R. Niola*; Naples/IT*
(francescogiurazza@hotmail.it)

Purpose: Acute adrenal haemorrhages are a rare event compared to other abdominal visceral injuries because of the anatomic localisation of the adrenal glands. The main causes are trauma and ruptured neoplasms.
This manuscript reports on a single-centre experience of transarterial embolisations of adrenal haemorrhages in an emergency setting.

Methods and materials: In this retrospective analysis from 2010 to date, 17 patients (12 men and 5 women, mean age: 59.8 years) presenting with adrenal bleedings were treated by endovascular embolisation.
The aetiology was traumatic in 7 cases, ruptured neoplasm in 8 cases, and spontaneous in 2 patients assuming oral anticoagulant therapy.
After thin slice contrast-enhanced CT, a super-selective embolisation was conducted with different embolising agents according to the type of vessel lesion and operator preference.
Results: Technical success rate, considered as an interruption of adrenal bleeding detectable at angiography, was 94.1%.
Clinical success rate, considered as haemodynamic stability restoration within 24 hours from the procedure, was 82.3%.
The vessels involved were the superior adrenal artery in 5 patients, the middle adrenal artery in 8 patients, the inferior adrenal artery in one patient, and more than one adrenal artery in 3 patients.
No procedure-related major complications occurred and no patients had infarctions, necrosis, abscess formation, or required long-term steroid supplementation.
Conclusion: Acute adrenal haemorrhages can be safely and effectively managed by catheter-directed embolisations. The source of bleeding has to be carefully investigated at CT and angiography as adrenal glands present with a wide and complex vascular arterial network.
Limitations: This is a retrospective analysis and therefore bias selections should be considered. The number of patients is small, however, this is due to the low frequency of the scenario.

Resting-state functional magnetic resonance imaging in predicting the long-term functional outcome after acute ischaemic stroke

E. Camacho-Ramos[1], A. Jimenez-Pastor[1], C. Biarnés[2], A. Alberich-Bayarri[1], S. Pedraza[2], J. Serena[2], M. Terceño[2], Y. Silva[2], J. Puig[2]; [1]Valencia/ES, [2]Girona/ES (educamacho@quibim.com)

Purpose: Stroke is one of the main causes of disability in adults. Resting-state functional magnetic resonance imaging (rs-fMRI) is able to map functional-anatomic networks by analysing spontaneously correlated low-frequency activity fluctuations across the brain. However, the role of rs-fMRI to predict the functional outcome after acute stroke remains unclear. We aimed to evaluate the impact of rs-fMRI at 72h after stroke symptoms onset to predict the functional outcome at 1-year follow-up.
Methods and materials: 35 reperfused stroke patients (12 female, age: 68±14 years, 3-day national institutes of health stroke scale (NIHSS) score: 6±5) were consecutively scanned 72 hours after symptom onset. A modified Rankin scale (mRS) was used to evaluate functional outcome at 90 days (patients with good functional outcome, mRS ≤2; poor outcome, mRS>2). Image pre-processing included motion and slice-timing correction, outliers' detection, brain tissue segmentation, MNI space normalisation, smoothing, and band-pass filtering to remove undesired components. Region-of-interest analyses were performed to calculate the correlation coefficients for every pairwise region and a weighted general linear model was used to discover significative differences ($p<0.05$ FWE) between groups.
Results: Patients with good outcome presented higher intra-network connectivity, while patients with poor outcome showed lower inter-network connectivity. To predict the 1-year functional outcome after a stroke, the 3-day NIHSS score was the most relevant predictor. An accuracy of 74.3% was obtained through a discriminant model using only clinical scores. Adding anatomical networks increased accuracy to 88.6%, 97.1% (including functional networks), and 100% (with clinical and imaging variables).
Conclusion: These results show the relevance of rs-fMRI in the acute phase to predict the long-term functional outcome in stroke patients.
Limitations: The sample size.

The application of resting and task state fMRI in common exotropia

Y. Song[1], J. Chu[2], H. Han[1]; [1]Xiamen/CN, [2]Guangzhou/CN (xiaohongmao1992@163.com)

Purpose: This study applied brain resting and task state fMRI to detect the changes of brain activity and explore the mechanism of neurological damage in adult patients with common exotropia.
Methods and materials: 20 patients (M:10, F:10) and 20 age- and sex-matched controls with normal corrected visual acuity from 18 to 26 years of age were enrolled in this study. Two independent samples t-tests were employed to measure the differences of regional homogeneity (ReHo) and amplitude of low-frequency fluctuation (ALFF) in the resting-state fMRI and the brain-activity difference in the visual stimuli task fMRI of two groups.
Results: Compared with healthy controls, patients had significantly higher ReHo in the right middle occipital gyrus and the left supramarginal gyrus, and lower values in the right cingulate gyrus, the right precentral gyrus, the right superior temporal gyrus, and the left frontal sub-gyral lobe ($P<0.05$). Patients showed a reduced ALFF in the left superior parietal lobe, the right middle cingulate gyrus, the left anterior cingulate gyrus, and the right inferior temporal gyrus ($P<0.05$). Moreover, under the condition of binocular 2D visual task stimulus, the brain activity increased in the left superior frontal gyrus, the right superior orbital frontal gyrus, the bilateral inferior orbital frontal gyrus, and the left rectus gyrus in the patient group. Meanwhile, the brain activity of the left postcentral gyrus and the left precuneus gyrus increased under binocular stereo-stimulation.
Conclusion: Common exotropia may lead to disorders in the processing of visual-spatial information and the control of emotion and attention.
Limitations: The small case sample.

BOLD fMRI mapping of the language network: comparative assessment of task-based and resting-state fMRI

V. Lolli[1], S. Wastling[2], L. Mancini[2]; [1]Brussels/BE, [2]London/UK (valentina.lolli@erasme.ulb.ac.be)

Purpose: Task-based fMRI is the method of choice for determining the hemispheric dominance of language function. One important limitation is that the technique depends on the patient's ability to perform the task.
The aim of our study was to test the feasibility of using resting-state fMRI instead of task-based approaches.
Methods and materials: 15 healthy native English speakers underwent resting-state fMRI and two language fMRI paradigms: a verbal fluency (VF) and one verb generation (VG).
Task-based fMRI was analysed using both a general linear model (GLM) in the SPM software and independent component analysis (ICA).
Resting-state fMRI data was analysed by using both ICA and principal component analysis (PCA) using the SPM CONN toolbox, assuming a fixed number of 20 components. Resting-state networks were extracted by using both an automated template procedure and visually by two experts (VL and LM).
Results: The VG paradigm was more accurate than the VF paradigm or combination of the two and was therefore selected for further analyses.
Some of the networks labelled as language networks by the software were considered inappropriate and discarded by the experimenters.
There was a poor overlap between resting-state and task-related areas of activation as assessed by calculating the Dice similarity coefficients (mean:

0.1815) using the masks from the VG task GLM analysis, and the selected resting-state components.
The laterality index (LI) values of resting-state networks were significantly lower (mean: -0.0165) than the LI of the VG task map (0.4846).
Conclusion: Our results do not support the use of resting-state fMRI instead of task-based fMRI for hemispheric dominance assessment.
Limitations: Our sample is relatively small and heterogenous.
Ethics committee approval: Written informed consent was obtained from all subjects.
Funding: This work was part of the UCLH Project ID number: 09/H0716/18.

Machine learning analysis in the diagnosis of medication overuse headache: a resting-state functional magnetic resonance imaging study
C. Yang, L. Yao, S. Lui*; Chengdu/CN*

Purpose: Medication-overuse headache (MOH) is a psychiatric comorbidity associated with chronic migraine. As machine learning is capable of identifying subtle disease patterns on a single subject level, we sought to determine the differences between MOH patients from healthy controls by using a machine learning classifier on resting-state functional MRIs (rs-fMRI).
Methods and materials: 34 patients with MOH and 41 age and sex-matched healthy controls were recruited. Smooth mean regional homogeneity (smReHo) was obtained via DPARSFA. Support vector machine (SVMs) algorithms based on PRoNTo toolbox were used to explore the utility for smReHo in the differentiation of patients and controls individually. Finally, Pearson's correlation between the MOH patients and clinical measurement was investigated.
Results: The balanced accuracy of the correct classification of MOH and controls was 72.03% for smReHo ($p<0.001$ during 1,000 permutation testing). Areas contributing to classification accuracy mainly included in right Heschl's gyrus (3.23%), left temporal pole, and right inferior temporal gyrus. The direct comparison showed that MOH patients had significantly decreased smReHo activation in the right Heschl's gyrus ($p<0.05$, FDR corrected), which was corresponding to the highest weight area by machine learning classifier. A negative correlation was observed between the duration of medication intake and smReHo activation in the right Heschl's gyrus ($r=-0.433$, $p<0.05$).
Conclusion: With machine learning computational analyses, our study was able to diagnose MOH patients on a single subject level by demonstrating decreased regional function in MOH patients, notably involving the right Heschl's gyrus, suggesting the right Heschl's gyrus might play an important role in the pathogenesis of MOH.
Limitations: Studies with larger samples may be required for further verification.

The reorganisation of language networks after temporal lobe epilepsy surgery: a clinical fMRI study
O. Foesleitner[1], K.-H. Nenning[2], V. Schmidbauer[2], B. Sigl[2], J. Hainfellner[2], G. Langs[2], D. Prayer[2], G. Kasprian[2]*; [1]Heidelberg/DE, [2]Vienna/AT (benjamin.sigl@meduniwien.ac.at)*

Purpose: The reorganisation of language is common in epilepsy patients and a relevant factor in surgical therapy. The non-invasive gold standard in presurgical evaluation is language fMRI. fMRI network analysis could reveal subtle changes in language network architecture so far invisible with standard analyses and thus provide relevant additional information. We aimed to investigate the reorganisation processes of language networks in surgical patients with temporal lobe epilepsy (TLE) using standard fMRI activation and recent network analysis.
Methods and materials: Task-based language fMRIs were performed on 28 TLE patients (16 right/12 left) before and after surgery, and on 22 healthy controls. FMRI activation analysis, a derived laterality index, and functional connectivity of global and language networks were used to investigate language architecture. Naming, semantic, and phonematic verbal fluency were correlated with imaging parameters.
Results: Both left and right TLE were associated with widespread language network alterations, particularly ipsilesional, before, and more pronounced after surgery. Preoperatively, mesiotemporal connectivity was decreased in left TLE, while postoperatively bihemispheric changes with a shift to more atypical language laterality (especially frontal) occurred. In right TLE, right intrahemispheric frontotemporal functional connectivity was attenuated before and further decreased after surgery, while those patients with stronger connectivity scored worse in semantic verbal fluency. Better postoperative naming ability was generally accompanied by stronger interhemispheric frontal connectivity. In all cases, network analysis revealed more widespread alterations than activation analysis.
Conclusion: The reorganisation of language function is a visualisable phenomenon in left and right TLE, both before and after surgery. Functional connectivity analysis reveals more widespread network changes than fMRI activation analysis and may offer a more comprehensive view on language architecture. Some connectivity measures may serve as biomarkers for language performance.

Dynamic functional connectivity alterations of trigeminal neuralgia in resting-state fMRIs
X. Wan[1], P. Zhang[2], W. Wang[1], X. Su[1], S. Zhang[1], Q. Gong[1], Q. Yue[1]*; [1]Chengdu/CN, [2]Lanzhou/CN (awan1204@163.com)*

Purpose: Functional connectivity abnormalities, such as default mode network (DMN), have been reported previously in trigeminal neuralgia (TN) of which chronic pain is a common symptom. However, little is known about the dynamic functional connectivity (dFC) in patients with TN.
Methods and materials: 29 patients with TN were enrolled in this study and underwent rest-functional MRI scanning along with 24 age-, sex-, and education-matched healthy control (HC) subjects. A sliding-window approach was used to study the dFC based on the GIFT (group ICA of fMRI toolbox).
Results: The functional networks were arranged into DMN, auditory network (AUD), visual network (VIS), and ventral attention network (VAN). Dynamic analysis suggested 4 distinct connectivity 'states' across the entire group (state I for 24%, state II for 16%, state III for 35%, and state IV for 25%) and a larger proportion of state III and a smaller proportion of state IV were observed compared with HC group ($p=0.0000$ and $p=0.0058$, respectively). Furthermore, the TN group showed decreased connections between networks (DMN-VIS, AUD-VIS, and VIS-VAN). Our analyses showed that increased dwell time in the state IV was associated with the presence of pain in TN.
Conclusion: Our study indicates that chronic pain in TN is characterised by altered temporal properties in dynamic connectivity. Further studies on dynamic functional connectivity could help to better understand the progressive dysfunction of networks in TN.
Limitations: Correlation analysis is in progress.

Resting-state network plasticity in low-grade glioma patients before and after resection: maintaining language skills
L. van Dokkum, S. Moritz Gasser, J. Deverdun, G. Herbet, N. Menjot de Champfleur, H. Duffau, F. Molino, E. Le Bars*; Montpellier/FR (l-vandokkum@chu-montpellier.fr)*

Purpose: Diffuse low-grade gliomas (DLGG) have a slow infiltrating character, allowing for simultaneous plasticity and maintaining the patients' functional capacity. Here we addressed whether and how anatomical disconnection following left-hemispheric DLGG growth and resection interferes with resting-state connectivity, specifically in relation to language.
Methods and materials: 39 native French persons with a left DLGG were included and underwent awake surgical resection of the tumour. The anatomical disconnectivity risk following the DLGG volume and the resection, and the functional connectivity of resting-state fMRI images in relation to language, were evaluated prior to and three months after surgery. Resting-state connectivity

patterns were compared with 19 healthy controls. Language was assessed with a picture-naming task.
Results: Adaptive plasticity was observed in regions around the tumour/cavitas area, with increased connectivity of the left and right inferior parietal lobule with the left inferior temporal gyrus. Picture naming was surprisingly not dependent on the connectivity of the language network, but of the connectivity of regions know to be involved in semantics, in which their specific role could be explained in the light of the broader resting-state network they took part in. Also, the recruitment of the frontoparietal attention network was observed.
Conclusion: A whole-brain approach with specific clinical data input is required for meaningful resting-state analysis in case of lesions. Pre-surgical local plasticity and functional compensation by increased task-directed attention allow a relative high level of performance maintenance after DLGG resection.
Limitations: All participants underwent intensive speech-language rehabilitation post-surgery, which might have trained and strengthened attentional resources. The compensational strategy might thus have been learned.
Ethics committee approval: The study received local ethical committee's approval. Participants gave informed consent.

Thalamic structural connectivity abnormalities in minimal hepatic encephalopathy: a probabilistic tractography study
T.-X. Zou, N.-X. Huang, H.-J. Chen*; Fuzhou/CN (ztx6861@163.com)*

Purpose: There have been accumulating studies demonstrating thalamic related structural, functional, and metabolic abnormalities in minimal hepatic encephalopathy (MHE). We conducted the first study to investigate thalamic-related structural connectivity alterations in MHE.
Methods and materials: Diffusion based probabilistic tractography was used to determine the structural connection between the thalamus and the cortical/subcortical regions in 22 cirrhotic patients with MHE, 30 cirrhotic patients without MHE (NHE), and 30 healthy controls. DTI (diffusion tensor imaging) measurements of these thalamic connections, including connectivity strength (CS), fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD), were calculated and compared across three groups. Neuropsychological assessment was performed as well. The correlation analysis was conducted to investigate the relationship between neuropsychological performance and the measurements about thalamic connections. Machine-learning classification analysis was performed to estimate whether diffusion measurements can distinguish MHE from NHE.
Results: The probabilistic tractography revealed thalamic structural connection, which was disturbed in cirrhotic patients (reflected by decreased CS/FA and increased MD/AD/RD). Abnormal thalamic connection primarily involved the prefrontal cortex, sensorimotor cortex, parietal cortex, medial temporal cortex, hippocampus, and striatum. Thalamic connectivity abnormalities deteriorated from NHE to MHE and correlated with patients' impaired neuropsychological performance. The relatively high classification accuracy was obtained using CS as a discriminating index.
Conclusion: Our results demonstrated the altered thalamic structural connectivity with both cortical and subcortical regions in MHE. The disturbed thalamic connectivity may underlie the mechanism about cognitive deficits in MHE and can serve as biomarker for the diagnosis of MHE and monitoring disease progression.
Limitations: The cross-sectional design.

RPS 1611-9 16:48
Assessment of translingual neurostimulation in the treatment of children with cerebral palsy in the late residual stage by means of a functional MRI
A. Sokolov, A. Efimtsev, D. Chegina, T. Ignatova, V. Fokin*; St. Petersburg/RU (falcon.and@mail.ru)*

Purpose: Constant stimulation of the nervous system is one of the most popular ways to activate neural networks in order to activate the brain and initiate neuroplasticity processes. The purpose of the study was to evaluate the impact of translingual neurostimulation of the brain to balance, coordination of movement, and the ability to form new motor skills in children with cerebral palsy in the late residual stage.
Methods and materials: This study involved 6 children with cerebral palsy, a form of spastic diplegia. Patients had intact intellect and no seizures in anamnesis. All children received standard treatment, including massage, medical-gymnastics with simulators, 10 daily sessions of physical therapy and neurostimulation of the brain (using a device for electrotactile stimulation called PoNS (portable neurostimulator)).
Patients underwent functional MRI of the brain before the start of, and at the end of, the course of treatment. The research was carried out using movement functional paradigms for each extremity (both feet and hands) and an active "count" paradigm for patients who could perform the task for the count and depending on clinical status, and passive movement or sensory paradigms were performed for those who could not. Postprocessing was carried out using the software package SPM 12.
Results: All patients noted decreased muscle tone and improved balance and coordination functions after neurostimulation. According to obtained fMRI data, patients who underwent translingual neurostimulation showed increased activation in the right-hand motor area and activation in the foot motor area in response to the stimuli.
Conclusion: Translingual neurostimulation is innovative in the field of neurostimulation, non-invasive, and safe and easy to use. fMRI active paradigms, with proper and high-quality implementation, is an auxiliary method for the objective control of treatment efficiency.

Altered structural and functional connectome in unilateral sudden sensorineural hearing loss
W. Fan*; Wuhan/CN (fwl@hust.edu.cn)*

Purpose: To investigate the alterations of brain structural and functional connectome in unilateral sudden sensorineural hearing loss (USSHL) patients.
Methods and materials: We constructed functional-structural connectomes for USSHL patients (41 for the left side and 44 for the right side) and 85 controls. Graph theoretical analysis was employed to evaluate the network properties of functional-structural brain connectome. Moreover, we quantified coupling between functional-structural connectome by the correlation between functional-structural connectome edges within non-zero structural connectivity areas. The coupling of functional-structural brain connectome was compared by using permutation tests. To investigate the clinical relevance of altered brain network topologies in USSHL, Pearson's correlation analysis was performed between the clinical variables and the topological properties.
Results: Compared with the control groups, both groups of USSHL patients exhibited a significantly increased clustering coefficient, global efficiency, and local efficiency, but a significantly decreased characteristic path length in functional brain connectome, while a significant decrease clustering coefficient and local efficiency in structural brain connectome. In addition, the primary increased nodal strength was observed in limbic and paralimbic systems primarily as well as in the auditory network brain areas. More importantly, the coupling strength of structural-functional connectome was decreased and exhibited a negative correlation with some USSHL clinical variables in patients.
Conclusion: Detectable alteration of network organisation already occurred in USSHL patients within the acute period at the global and regional level. The functional connectome is characterised by a shift toward small-worldization while the structural connectome is toward randomisation, which may indicate a plastic reorganisation procedure of the brain to compensate for the loss of hearing in USSHL. Moreover, the degree of coupling between structural-functional connectome was decreased, which may reflect the pathophysiological mechanisms of USSHL.

On the relevance of functional-structural correlations in the multimodal MRI workup of neurosurgical cases
L. R. Kozák, G. Gyebnár*; Budapest/HU (lrkozak@gmail.com)*

Purpose: To investigate whether multimodal network graph analyses are relevant in the discussion of the combined fMRI-DTI pre-surgical evaluation of language networks.
Methods and materials: A retrospective cross-sectional evaluation of our 39 consecutive patients who underwent pre-surgical BOLD fMRI with 4 language tasks (TR=3s, 3x3x3 mm voxels) was conducted. DTI (32 encoding directions, b=800 s/mm^2, 2 mm isotropic resolution) was done with a standard SPM12 (https://www.fil.ion.ucl.ac.uk/spm) pipeline for fMRI, with the resulting activation maps further analysed using ICN_Atlas (Kozák et al., NeuroImage, 2017) with AAL atlas ROIs (Tzourio-Mazoyer et al., Neuroimage, 2002). DTI data was analysed using ExploreDTI with whole-brain tractography (Leemans et al., ISMRM, 2009) resulting in AAL-based connectivity matrices. Structural connectiome characteristics calculated with the brain connectivity toolbox (Rubinov and Sporns, NeuroImage, 2010) were compared against fMRI-based language network parameters using conventional parametric statistics in Matlab, focusing on Broca's and Wernicke's areas bilaterally.
Results: fMRI lateralisation correlated significantly with structural connectome graph parameters in a task-dependent fashion. The temporal lateralisation of speech comprehension and auditory decision and the frontal lateralisation of picture naming and synonym decision showed significant positive correlations with network metrics-based lateralisation parameters of the temporoparietal areas. The lateralisation of frontal language areas was also reflected in the lateralisation of arcuate fasciculus (AF).
Conclusion: The temporal lobe language networks seem to have a defining role in whole-brain language organisation, shown by the observed functional-structural correlations that are in line with previous literature (Wylie and Regner, Neurosci, 2014; Propper er al., Brain Cogn, 2010). A proper multimodal presurgical workup is important for preserving language function.
Limitations: The heterogeneity of age and pathologies, and DTI data instead of HARDI.
Ethics committee approval: Semmelweis University IRB #153/2019 (retrospective cross-sectional).

Diffusion tensor tractography (DTT): an objective method of determining clinically relevant, compressive, spinal cord myelopathy
R. Rastogi, N. Jain*; Moradabad/IN (rajulrst@yahoo.co.in)*

Purpose: Magnetic resonance imaging (MRI) is the gold-standard imaging tool for compressive spinal cord myelopathy (CSCM). Diffusion tensor imaging (DTI), especially fibre-tracking or tractography (DTT), has been considered superior to routine MRI in predicting prognosis and urgency of decompression. This study aims to evaluate DTT as an advanced dimension of MRI in patients with CSCM in predicting the necessity of decompression management.
Methods and materials: 12 patients with clinical signs of CSCM underwent conventional MRI and DTI examination with a high-resolution matrix on a 1.5T magnet system. 3D-colour-coded maps were obtained in the sagittal and coronal planes. The presence or absence of parenchymal signal alteration and change in colour-code of the neural fibre tracts in the spinal cord, in addition to the integrity and homogeneous thickness of the fibre tracts on DTT, was evaluated. A near-homogeneous blue colour in the spinal cord and cauda equina was considered normal in our study, with the blue colour representing diffusion in the craniocaudal direction. Alteration in colour, thickness, and integrity, especially at the level of compression on T2W images, was considered significant.
Results: Out of 12 patients, 9 had signs of CSCM secondary to infective spondylodiskitis, 1 secondary to a disk protrusion, 1 secondary to a disk extrusion, and 1 secondary to the metastatic collapse of the vertebra.
In 8/12 patients with no spinal cord parenchymal signal alteration on T2W images, DTT revealed significant alteration in the colour-code both at and above the level of compression, signifying altered diffusion.
Conclusion: DTT is a more sensitive indicator of spinal cord compression than conventional MRI by revealing colour alterations, thinning and loss of integrity of spinal nerve fibre tracts, and providing an easy and fast tool to predict the need for surgical decompression.

The role of the waist-to-hip ratio in brain networks: a connectometry study
M. Porcu, E. Scapin, P. Garofalo, A. Caneglias, F. Destro, A. Operamolla, L. Saba*; Cagliari/IT (micheleporcu87@gmail.com)*

Purpose: It is known from the literature that BMI influences cerebral networks. The purpose of this study is to evaluate the influence of the waist-to-hip ratio (W-H ratio) on brain networks by using the connectometry technique.
Methods and materials: We recruited 30 healthy subjects (12 males, 18 female; age 25-80). The waist and hip circumferences of every patient were measured in order to calculate the W-H ratio and on the same day an MR examination was performed on a 3T scanner (Vantage Titan 3T, Canon) with a 32 channels head coil. The MR protocol included a 40 directions DW sequence for the connectometry analysis. The connectometry analysis was performed using a linear regression model to consider the effects of the W-H ratio, choosing three different T-score thresholds (T-threshold) values (1, 2, and 3). Results were considered statistically valid for a p-value adjusted for the false discovery rate (p-FDR) <0.05. The network topology analysis measured the influence of the W-H ratio on brain networks.
Results: The connectometry analysis identified several white matter bundles negatively correlated to the W-H score for T-threshold=2 and 3. Several properties of the network were influenced in the network topology analysis.
Conclusion: The W-H ratio influences brain networks. More studies are needed in order to fully understand these results.
Limitations: The small number of patients recruited and the DW parameters adopted, in particular, the low b-values.
Ethics committee approval: The study was approved by the local ethical committee. Informed consent was obtained.

Neural correlates of insight and analytical anagram solving: fMRI study
E. Kremneva, D. Sinitsyn, I. Bakulin, A. Poidasheva, A. Medyntsev, D. Lagoda, L. Legostaeva, N. Suponeva, M. Piradov*; Moscow/RU (kremneva@neurology.ru)*

Purpose: Insight is the sudden and unpredictable appearance of a problem's solution. The role of various brain structures in the generation of the insight phenomenon remains poorly understood. We aimed to study the neural correlates of the insight process during fMRI.
Methods and materials: We performed fMRIs in 32 healthy subjects with a paradigm that involved solving anagrams. After giving an answer, the participants labelled their strategy as 'insight' or 'analytical'. The data was analysed using a GLM with predictors corresponding to different stimulus types and button presses. A random-effects analysis for the population was performed using a t-test over the individual contrast images.
Results: Areas activated during 'insight' problem-solving compared to rest included bilateral middle/superior frontal gyri, bilateral anterior insula, left frontal operculum, left precentral gyrus, left supplementary motor cortex, left superior parietal lobule, left putamen, left pallidum, right cerebellum, and bilateral inferior occipital gyri. Areas activated during 'analytical' problem-solving compared to rest included right superior frontal gyrus, bilateral anterior insula, left frontal operculum, left precentral gyrus, left supplementary motor cortex, bilateral superior parietal lobules, right cerebellum, left putamen, and bilateral inferior occipital gyri. Activation of the left precentral gyrus, left supplementary motor cortex, and right cerebellum during both insight and analytical solving can be attributed to right-hand movement for keystroke at the "solving" moment. The contrast between the 'insight' and 'analytical' problem-solving did not contain significant clusters at FWE<0.05.

Conclusion: Both analytical and insight solving are associated with the activation of multiple brain regions without significant difference in activation areas between strategies. Future studies using different paradigms and combined methods (fMRI, EEG, NIBS, etc.) are needed to elucidate neural correlates of insight.

Language lateralisation in tumour patients and healthy controls using functional MRI and diffusion tractography
A. Q. Y. Al Busaidi[1], E. Gangemi[2], S. Wastling[1], A. S. van Den Berg[3], L. D'anna[1], L. Mancini[1], T. A. Yousry[1]; [1]*London/UK,* [2]*Rome/IT,* [3]*Dordrecht/NL (ayisha.albusaidi@nhs.net)*

Purpose: Our retrospective study investigates whether a correlation exists between functional language lateralisation using fMRI and structural lateralisation using diffusion data of language tracts in controls and tumour patients.
Methods and materials: 15 controls and 61 patients were included and underwent structural, functional, and diffusion imaging on 3T MRI. Subjects performed verbal fluency and verb generation language fMRI tasks, and a laterality index (LI) was calculated using data from the cerebral hemisphere and the contralateral cerebellar hemisphere. The diffusion tracts included the long fibres of the arcuate fasciculus, anterior and posterior short fibres of the arcuate fasciculus, uncinate fasciculus, inferior longitudinal fasciculus, inferior fronto-occipital fasciculus, and frontal aslant tract. An asymmetry index (AI) for each fibre pair was calculated using the tract volume derived from single tensor (ST) and spherical deconvolution (SD) diffusion data, as well as using the hindrance modulated orientational anisotropy (HMOA) derived from the SD method. A linear regression analysis between fMRI LI and DTI AI was performed.
Results: In all subjects, there was no significant correlation between fMRI LI and DTI AI for any of the tracts.
Conclusion: Our results do not justify replacing fMRI with tractography in the assessment of language lateralisation. The discordant results between ST- and SD-based asymmetry indices indicate that the structural lateralisation is less robust than the functional one.
Limitations: The predominately left-sided tumour distribution is due to the retrospective design, as included patients had all been selected clinically for presurgical assessment. The number of right-handed, left-handed, and ambidextrous subjects was not balanced. Disrupted or infiltrated fibres were excluded.
Ethics committee approval: The National Hospital for Neurology and Neurosurgery and Institute of Neurology Joint Research Ethics Committee approval was obtained.
Funding: No funding was received for this work.

Diagnostic and clinical value of dual-source computed tomography in pulmonary atresia with ventricular septal defect
X.-Z. Zhou, K. Shi, Z.-G. Yang*; Chengdu/CN (xinzhuzhou@126.com)*

Purpose: To explore the diagnostic and clinical value of dual-source CT (DSCT) in pulmonary atresia with ventricular septal defect (PA-VSD).
Methods and materials: The clinical and imaging data of 35 patients with PA-VSD confirmed by surgery or digital subtraction angiography (DSA) were retrospectively analysed. The results of preoperative transthoracic echocardiography (TTE) and DSCT were compared with those of surgery or DSA.
Results: DSCT and TTE all have high sensitivity and specificity in the diagnosis of intracardiac anomalies and anomalies of great vessels, the difference is not statistically significant ($p > 0.05$), while the sensitivity of DSCT in diagnosing PA-VSD patients with major aortopulmonary collateral arteries (MAPCAs) was higher than that of TTE (100% vs 68.75%). The incidence of MAPCAs in the group of the large ventricular septal defect (57.7%) is higher than non-large ventricular septal defect group (11.1%) diagnosed by DSCT, the difference is statistically significant（$p=0.018$, < 0.05. Based on DSCT images, McGoon ratio, Nakata index and TNPAI index of patients were measured. There were significant differences in McGoon ratio and TNPAI index between different treatment groups ($p < 0.05$).
Conclusion: DSCT can accurately diagnose PA-VSD and associated cardiovascular malformations, evaluate the development of pulmonary artery and anatomical characteristics of MAPCAs. It has great reference value for diagnosis and the choice of treatment methods of PA-VSD.
Limitations:
Firstly, the sample size of this study is relatively small, which limits the application of the research results. Secondly, because this study is a retrospective study, the surgical methods are affected by the personal habits of the operator partly, which makes the results of the study have certain limitations and need further verification of randomised clinical trials.
Ethics committee approval: Institutional Review Board at West China Hospital of Sichuan University approved this study.
Funding: No funding was received for this work.

The feasibility and radiation dose of single-beat coronary CT angiography in patients with atrial fibrillation
C. Zhao, Z. Yang*; Beijing/CN (chenglin.zhao@163.com)*

Purpose: To evaluate the feasibility and radiation dose of single-beat coronary CTA in patients with atrial fibrillation (AF) compared sinus rhythm (SR).
Methods and materials: From 2016 to 2017, 20 patients with AF (group A) and 20 patients with SR (group B) were referred for CCTA with120 kVp tube voltage and auto mAs. The objective IQ including image noise, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were compared respectively. The subjective IQ was evaluated by two radiologists in consensus (1 excellent, 2 good, 3 adequate, 4 poor). The effective radiation dose was calculated for each patient.
Results: Group A (8 male, 12 female, mean age 59.1±15.1years, BMI 28.4±5.1kg/cm^2), group B (8 male, 12 female, mean age 54.8±18.6 years, BMI 29.0±6.5 kg/cm^2) ($p>0.05$) were recruited. The image noise, CNR and SNR of the 2 groups were 28.7±5.8(A) vs 29.1±5.6(B) ($p>0.05$), 18.4±5.1(A) vs 18.5±6.7(B) ($p>0.05$) and 15.3±4.4(A) vs 15.4±5.9(B) ($p>0.05$). The subjective IQ of the 2 groups based on patients were all rated as diagnosable and the scores were 1.4±0.7(A) vs 1.6±0.7(B) ($p>0.05$); based on the artery segments, 261 segments (A) and 258 segments (B) of the 2 groups were evaluated, 100% (261/261) and 99.6% (257/258) were rated as diagnosable and the scores were 1.16±0.4(A) vs 1.24±0.5(B) ($p=0.02$). The mean effective radiation dose (ED) were 3.5mSv±1.1mSv vs 2.9 mSv±1.2mSv, ($p>0.05$).

Conclusion: Single-beat CCTA using wide-detector CT could achieve high rate of success and good IQ for AF patients and with acceptable ED compared with SR patients.
Limitations: A systematic comparison of diagnostic accuracy between CCTA and the gold standard of invasive coronary angiography has not been performed.
Ethics committee approval: We performed this study with the approval of the local institutional review board.
Funding: No funding was received for this work.

Screening potential of low-dose chest CT in assessing the degree of coronary arteries calcification

O. V. Styazhkina, K. Zhuravlev, V. E. Sinitsyn*; Moscow/RU (olya-mma@mail.ru)*

Purpose: Coronary artery calcinosis is a specific biomarker of coronary atherosclerosis. It is often detected on chest CT scans. Today the popularity of lung cancer screening with low-dose CT is growing. The aim of the study is to compare the diagnostic value of low-dose chest CT for the assessment of calcium score in comparison with the standard gated calcium scoring.
Methods and materials: Non-gated low-dose chest CT and gated calcium scoring were performed in 251 asymptomatic patients. The Agatston calcium score values obtained from low-dose CT and gated scans were analysed independently by two radiologists. Inter-observer and inter-technique agreement were evaluated (data with "zero" calcium scores was excluded). Inter-technique differences in a stratification of patients into five risk categories (scores 0, 1-100, 101-400, 401-1000 and> 1000) using the kappa coefficient (k) were analysed.
Results: The sensitivity of non-gated calcium scoring compared to the standard technique was 95%, specificity - 99%. The proportion of "zero" calcium score values in our study was 31% (79 patients). The inter-technique concordance was quite high, both with the inclusion of "zero" values ($r=0.981$, $p<0.05$) and without them ($r=0.978$, $p<0.05$). The inter-observer agreement was 0.998. The inter-technique agreement in the stratification of patients into the five risk groups according to the calcium score values was also high: $k = 0.846$. Effective radiation dose in low-dose chest CT was significantly lower than in the case of gated calcium scoring (0.96 ± 0.26 vs 1.51 ± 0.22 mSv, $p<0.01$).
Conclusion: The study showed that non-gated low-dose chest CT can be effectively used both for lung cancer screening and coronary calcium scoring with lower radiation exposure to patients than in gated calcium score.
Limitations: No limitations were identified.
Ethics committee approval: n/a

Diagnostic performance of myocardial CT perfusion imaging for the detection of obstructive coronary artery disease: intraindividual comparison of half scan and multisegment reconstruction

D. Preuß, G. Garcia, M. Laule, M. Dewey, M. Rief*; Berlin/DE (daniel.preuss@mailbox.org)*

Purpose: To compare the diagnostic performance of half scan reconstruction (HSR) and multisegment reconstruction (MSR) of myocardial CT perfusion (CTP) imaging for the detection of obstructive coronary artery disease (CAD).
Methods and materials: A total of 134 consecutive patients (median age, 65.7 years; interquartile range, 55.9-70.2) prospectively underwent CTP. 93 patients had multisegment acquisition and were retrospectively interpreted for perfusion defects. In these patients, we performed both HSR and MSR and compared their diagnostic performance using ≥50% diameter stenosis in the supplying artery on quantitative coronary angiography as the reference standard. AUC and diagnostic performance were compared using DeLong et al.´s and McNemar´s approaches.
Results: Per-patient analysis revealed an overall AUC of HSR and MSR of 0.79 [95% confidence interval: 0.69, 0.88] and 0.65 [0.53, 0.78] (P= .01), respectively. Diagnostic accuracy of HSR was superior to MSR in patients with known CAD (74% (50 of 68) vs 63% (43 of 68); P< .001) and low heart rate variability (70% (39 of 56) vs 59% (33 of 56); P= .001). Diagnostic performance of HSR and MSR was the same in patients with suspected CAD (72% (18 of 25) vs 76% (19 of 25); P= .99) and heart rates ≥75 beats per minute (67% (20 of 30) vs 70% (21 of 30); P= .24).
Conclusion: HSR of myocardial CTP has a higher diagnostic performance than MSR in patients with known CAD and low heart rate variability. The two reconstruction methods have the same diagnostic performance in patients with suspected CAD and high heart rates.
Limitations: The subgroups have only a small number of patients.
Ethics committee approval: IRB approval and written informed consent were obtained.
Funding: No funding was received for this work.

CT-angiographic graft patency after minimally invasive multivessel coronary bypass surgery

O. Drozdova, M. Snegirev*; St. Petersburg/RU (olyadrozdova@yandex.ru)*

Purpose: Minimally invasive multivessel coronary artery bypass grafting (MICS CABG) has shown its safety, effectiveness and high rates of reproducibility, but graft patency data is lacking. In this study we retrospectively analyse CT-angiographic graft patency and mid- to early long-term outcomes in patients, subjected to MICS CABG in our institution.
Methods and materials: 245 patients were subjected to MICS CABG by small left side thoracotomy approach between July 2014 and December 2018. LITA harvesting, proximal and distal anastomoses were performed under direct vision. SVG/radial artery conduits were harvested endoscopically. Patients were examined with 128-slice CT coronary angiography. Angiographic results achieved for 127 (51.8%) patients (mean follow-up 31.1±7.8 months, range 15 – 45 months).
Results: All patients achieved complete revascularisation. The mean number of grafts was 2.6±0.5. Perioperative mortality was 0.4% (1 patient). There were 2 conversions to sternotomy (0.8%), 4 reopenings for bleeding (1.6%), 3 perioperative MI (1.2%) and 1 CVA (0.4%). 22 (9.0%) patients received transfusions. 83.2% of patients were followed-up clinically (range 12 – 56 months). Long-term mortality was 4.4% (9 patients). Stroke at follow-up occurred in 3 patients (1.5%). Repeat revascularisation was performed in 5 cases (2.4%). Overall graft patency rate in the examined patients was 89.8%. LITA graft patency rate was 98.4%. SVG grafts were patent in 84.0% of cases.
Conclusion: MICS CABG allows complete surgical revascularisation with the standard alignment of coronary grafts. Excellent perioperative and longer-term clinical results with promising angiographic graft patency rates have been achieved.
Limitations: This study is limited by the fact that it is a retrospective study.
Ethics committee approval: n/a

Evaluation of segmental viable myocardium using low-dose dobutamine stress cardiac MRI with tissue tracking

B. He, F. Gao*; Chengdu/CN (bohetmu@163.com)*

Purpose: To detect survived myocardium by low-dose dobutamine stress with tissue tracking using cardiac magnetic resonance (CMR) imaging and evaluate the prognosis of survived myocardium.
Methods and materials: In 24 adult SD rats, the left anterior descending coronary artery was occluded for half hours and released. Low-dose dobutamine stress cardiac cine-MR and late gadolinium enhancement were both performed to analyse wall motion of left ventricle. A three-dimensional and two-dimensional strain of anterior wall and anterior septum, include global peak longitudinal strain (GPLS), radial strain (GPRS), circumferential strain (GPCS), peak radial strain (PRS) and circumferential strain (PCS), were measured at baseline, after reperfusion and dobutamine stress. Triphenyl tetrazolium chloride (TTC) and Evans blue staining were applied to assess viable or nonviable myocardium.
Results: During baseline, statistical significance of GPLS, GPRS, GPCS, PRS and PCS dose are not present between viable and nonviable myocardium group ($P>0.05$), same as that observed after reperfusion except strain decrease without significance ($P>0.05$). While low-dose dobutamine stressing, PRS and

PCS of viable myocardium group increased significantly compared with that detected after reperfusion (P<0.05). Significant variances were presented between viable and nonviable myocardial group during stress. In addition, there was a significant difference between two-dimensional strain measured from cine-MR at rest and with stress. Strain variance of nonviable myocardium group during dobutamine stress dose not observe compared that detected after reperfusion (P>0.05).
Conclusion: The application of low-dose dobutamine stress cardiac MR with tissue tracking may provide an objective and accurate method to evaluate survived myocardium.
Limitations: The data still has to be interpreted with caution given the small sample size.
Ethics committee approval: This study was approved by Institutional Animal Research Committee of our local institute.
Funding: The study was funded by the National Natural Science Foundation of China (8193000682).

MyT3 16-7 16:24

Myocardial CT perfusion imaging for the detection of obstructive coronary artery disease: should interpretation of perfusion defects be different depending on disease status?

D. Preuß, G. Garcia, M. Laule, M. Rief, M. Dewey*; Berlin/DE (daniel.preuss@mailbox.org)*

Purpose: To investigate whether perfusion defect (PD) interpretation of myocardial CT perfusion (CTP) should be different in patients with suspected or known coronary artery disease (CAD) for the detection of obstructive CAD.
Methods and materials: A total of 134 consecutive patients with known or suspected CAD prospectively underwent CTP. Rest and stress PDs were retrospectively interpreted in four reading categories (RC): RC 1 (stress volume positive), RC 2 (rest or stress volume positive), RC 3 (stress-induced PDs positive), RC 4 (stress-induced and partially reversible PDs positive). Detection of ≥50% diameter stenosis in the supplying artery on quantitative coronary angiography (reference 1) and intervention (reference 2) served as the reference standards.
Results: When using reference 1, per-patient analysis revealed AUCs of RC 1-4 of 0.74, 0.65, 0.62, and 0.72, respectively, in patients with known CAD. In these patients, AUC of RC 1 was higher than RC 3 (P= .03) and, respectively, AUC of RC 4 was higher than RC 3 (P= .006). In patients with suspected CAD, AUCs of RC 1-4 were the same (0.83, 0.86, 0.85, 0.88; all P> .05). When using reference 2, AUCs of RC 1-4 in patients with known CAD (0.61, 0.60, 0.67, 0.69) and, respectively, in patients with suspected CAD (0.75, 0.80, 0.76, 0.80) were the same at per-patient level analysis (all P> .05).
Conclusion: In patients with known or suspected CAD, every stress PD should be judged positive to detect obstructive CAD in myocardial CTP regardless of its presentation in rest.
Limitations: Study design is retrospective.
Ethics committee approval: IRB approval and written informed consent were obtained.
Funding: No funding was received for this work.

CT texture analysis of the myocardium in patients affected by aortic stenosis: a potential new tool?

F. Vaccher, G. M. Agazzi, M. Filippini, C. Fiorina, L. Lupi, M. Ravanelli, D. Farina*; Brescia/IT (filippo.vaccher0@gmail.com)*

Purpose: To assess the potential of texture analysis (TA) of native images of the interventricular septum to detect structural myocardial changes in patients with aortic valve stenosis (AVS), candidates to transcatheter aortic valve replacement (TAVI).
Methods and materials: Retrospective single-centre study on 210 CT-angiography exams performed for TAVI planning. Scans were obtained with dual-source CT scanner (Somatom Definition Flash, Siemens, Erlangen) with retrospective ECG-gated acquisition and bolus-tracking technique. Two-dimensional TA was performed using commercial software (TexRAD Ltd, Cambridge, UK), with a filtration histogram method, on polygonal regions-of-interest (ROI) manually drawn by a single operator on native axial sections reconstructed in diastole and systole; ROIs encompassed the interventricular septum below aortic valve level. Septal thickness (ST), ejection fraction (EF), and aortic valve area (AVA) were recorded in each patient, in order to correlate such parameters with TA features. Statistical analysis was carried out using the least absolute shrinkage and selection operator (LASSO) linear regression model. Significance was fixed at P=0,05.
Results: After LASSO analysis 10 TA features were significantly correlated with ST; a radiomic score was calculated (mean value 14,57) with linear regression coefficient 1,3389 ($p=2,22x10^{-11}$; $R^2=0,2299$). 12 TA features were significantly correlated with EF; a radiomic score was calculated (mean value 52,33) with linear regression coefficient 1,2790 ($p=5,39x10^{-16}$; $R^2=0,2804$). 8 TA features were significantly correlated with AVA; a radiomic score was calculated (mean value 0,6670) with linear regression coefficient 1,9824 ($p=2,55x10^{-5}$; $R^2=0,08807$).
Conclusion: TA features extracted for myocardial septum correlate with morphologic and functional parameters in patients affect by SA. The correlation with ST suggests a possible correspondence between TA features and myocardial fibrosis or disarray.
Limitations: The single-centre study, study design retrospective, small sample.
Ethics committee approval: All patients gave written consent to CT.
Funding: No funding was received for this work.

Early evaluation on left ventricular remodelling in patients with type 2 diabetes mellitus using MR tissue tracking

Y. Li, Z. Li, C. Xia*; Chengdu/CN (18108087220@163.com)*

Purpose: To estimate the clinical value of MR tissue tracking in the assessment of left ventricular remodeling in patients with type 2 diabetes mellitus.
Methods and materials: 29 patients with T2DM as well as 21 healthy controls were enrolled. Cardiac magnetic resonance（CMR）was used to obtain left ventricular function parameters while MR tissue tracking to get peak strains (PS. Radial PS, circumferential PS and longitudinal PS were calculated with global and 16 regional segments in DM and healthy controls. Together with LVEF, LVEDV and LV Mass, peak strains were compared between DM and controls.
Results: LVEF and global longitudinal PS, basal longitudinal PS were statistical significantly smaller for DM (-16.51±2.76 vs -18.00±2.15, $P<0.05$; and -11.26±3.69 vs -13.35±3.16 $P<0.05$; respectively). Global and segmental PS had a statistical significant correlation with LVEF (r=0.63, 0.407, 0.571, 0.517, -0.765, -0.667, 0.627, 0.243, 0.615, 0.655 , $P<0.05$ separately). Global and basal radial PS, mid longitudinal PS had a significant-good correlation with HaB1C (r=-0.375, -0.367, 0.381, $P<0.05$); separate PS had a poor diagnostic value while the union of apical radial PS, basal circumferential PS, global/basal/apical longitudinal PS had a relatively good sensitivity and specify to distinguish DM from healthy controls.
Conclusion: There is a statistically significant difference between DM and healthy controls on peak strain, which serves an early measurement of left ventricular remodelling which could potentially be included as a supplementary diagnostic procedure in the evaluation of DM.
Limitations: We didn't discuss the left ventricular systolic function of DM.
Ethics committee approval: The study was approved by our institutional review board and written informed consent was obtained from all participants.

Clinical implications of measuring epicardial adipose tissue quantity
A. Jermendy; *Budapest/HU (adam.jermendy@gmail.com)*

Purpose: Various adipose tissue compartments play an important role in the development of cardiometabolic diseases. The quantity of different fat compartments is influenced by genetic and environmental factors. In a classical twin study we sought to assess the heritability of epicardial adipose tissue (EAT) quantity in comparison to that of abdominal subcutaneous (SAT) and visceral adipose tissue (VAT) compartments. Furthermore, we aimed to evaluate the role of EAT in the pathomechanism of coronary artery disease (CAD).
Methods and materials: We investigated 202 healthy adult twin subjects in whom CT based EAT, SAT and VAT quantity measurement, as well as coronary CT angiography, was performed. For the heritability assessment, intra-pair correlations were calculated and robust structural equation modelling was used. We performed logistic regression analysis to evaluate the association between CAD and clinical risk factors.
Results: We demonstrated in our study that genetics have substantial, while environmental factors have only a modest influence on EAT, SAT and VAT volumes. Our findings show that common and specific genetic effects both play an important role in developing these phenotypes. None of the phenotypic appearances of EAT, SAT and VAT proved to be completely independent of the other two. According to our results, EAT quantity shows a significant association with the presence of CAD supporting the concept that EAT may have a role in the pathomechanism of developing CAD.
Conclusion: As the presence of strong genetic predisposition does not automatically translate to the development of clinical disease phenotype, early and continuous preventive efforts should be implemented in order to prevent obesity. Our results also suggest that it seems reasonable to involve EAT quantity into cardiovascular risk assessment tools.
Limitations: The limitations of this study lay in the fact that it is a single-centre, cross-sectional study.
Ethics committee approval: n/a
Funding: No funding was received for this work.

The use of CTPA in the evaluation of heart failure in the acute setting
L. O'halloran[1], J. O'brien[2]; [1]*Limerick/IE,* [2]*Dublin/IE (liamoh@gmail.com)*

Purpose: Heart failure is a clinical diagnosis characterised by non-specific symptoms such as dyspnoea, fatigue and oedema. The European Society of Cardiology recommends obtaining objective measures for heart failure in order to confirm a diagnosis. However, it can be challenging to obtain objective measures such as echocardiography in the acute setting. CTPA is conventionally used to outrule pulmonary embolus, however, CTPA provides great detail of the heart and lungs as a whole. The aim of this study was to investigate what role CTPA could play in diagnosing heart failure.
Methods and materials: We reviewed 230 CTPA results, of these we confirmed which of these patients had heart failure by confirming a heart failure diagnosis with BNP and echocardiogram criteria. We divided the groups into those who had heart failure and those that did not. We then analysed which features found on CTPA were most specific for a diagnosis of heart failure.
Results: In our study the most specific signs were shown to be left ventricular enlargement, left atrial enlargement and right ventricular enlargement. This was demonstrated using chi-square analysis; right ventricular enlargement (value = 5.426 P=0.02), left atrial enlargement (value = 4.9 P=0.027) and left ventricular enlargement (value = 5.692 P=0.017).
Conclusion: Several findings on CTPA were demonstrated to be quite specific for a diagnosis of heart failure which includes left ventricular enlargement, left atrial enlargement and right ventricular enlargement. Acute physicians should utilise, if available, recent CTPA results while awaiting echocardiography in determining the presence of heart failure in patients.
Limitations: Study based at a single centre. A prospective study would have highlighted CTPA's clinical utility.
Ethics committee approval: Obtained from University Hospital Limerick's ethics committee.
Funding: No funding was received for this work.

Compared with the left atrium, left atrial appendage function and myocardial remodeling, play a greater role in relapse of AF after radiofrequency ablation
X. Tian, C. Li, Y. Yuan; *Shijiazhuang/CN (tianx25@139.com)*

Purpose: To evaluate the role of the left atrium and left atrial appendage in the recurrence of atrial fibrillation (AF) after radiofrequency ablation.
Methods and materials: 63 patients with AF who underwent radiofrequency ablation for the first time were enrolled. According to the recurrence of AF after radiofrequency ablation, the patients were divided into the recurrence group (n = 20 cases) and non-recurrence group (n = 43 cases). All patients underwent a 256-slice spiral CT examination before the operation. The maximum volume of LAA (LAAVmax), minimum volume of LAA (LAAVmin), LAA emptying fraction (LAAEF), and LAA ejection volume (LAAEV), LAA volume strain (LAA-VS), maximum volume of LA (LAVmax), minimum volume of LA (LAVmin), LA emptying fraction (LAEF), LA ejection volume (LAEV), and LA volume strain (LAVS) were measured.
Results: The LAAVmax, LAAVmin, LAVmax, and LAVmin in the recurrence group were higher than those in the non-recurrence group ($P < 0.05$), while LAAEF, LAEF and LAA-VS in the recurrence group were lower than those in the non-recurrence group ($P < 0.05$). There was no difference in LA-VS between the two groups. LAAEF was an independent predictor of recurrence after radiofrequency ablation of AF. LAAEF < 44.68% had the highest predictive value for recurrence after radiofrequency ablation.
Conclusion: LAAEF is a predictor of recurrence after radiofrequency ablation of AF. Compared with LA volume strain, LAA volume strain which represented fibrosis of LAA myocardia is more useful in evaluating myocardial remodelling associated with recurrence of AF.
Limitations: Our team paid attention to patients' ECG and ambulatory ECG results through a clinic or telephone follow-up, but asymptomatic atrial fibrillation attacks may be omitted, leading to underestimation of recurrence rate.

A comparative study between cardiac computed tomography and magnetic resonance imaging in the assessment of cavopulmonary anastomosis
M. A. I. Gamal Elden[1], F. R. M. Elkafrawy[2], A. Soliman[3], M. Salah[4], A. Elmogy[1], A. Mourshed[1], A. Samir[1], S. Romeih[3], W. Elmozy[1]; [1]*Cairo/EG,* [2]*Alexandria/EG,* [3]*Aswan/EG,* [4]*Zagazig/EG (marwagamal2014@gmail.com)*

Purpose: Could MRI replace CT in the detection of veno-venous collaterals in cases of cavopulmonary anastomosis?
Methods and materials: The study involves 11 patients (three adult and eight children) who have complex heart anomalies and underwent bidirectional Glenn. They should have a normal renal function with no general contraindication for MRI, like claustrophobia or non-compatible pacemaker or cochlear implant. They were assessed by using MDCT and short protocol MRI (TWIST, contrast-enhanced (CE) 3D whole-heart and flow studies). The study is descriptive.
Results: The study includes four female and seven male patients. We arranged the results into minor and major collaterals detected by CT and CE 3D navigator as well as capability of the twist technique to show the contrast through both pulmonary arteries and if there are collaterals or not. CT and CE 3D navigator show minor and major venous collaterals with similar accuracy. Twist technique shows the contrast passing through both pulmonary arteries and collaterals yet it could not visualise the collaterals in four cases. MRI, the only method, to calculate flow in the venous collaterals.
Conclusion: CE 3D navigator beside TWIST technique can replace cardiac CT in the assessment of Glenn and collaterals. Additionally, MRI can measure the flow.
Limitations: The small number of cases.
Ethics committee approval: Written consent was taken from patients and/or their guardian to do CT and short protocol MRI.
Funding: No funding was received for this work.

Optimised short breath-holding time protocol for subtraction coronary CT angiography
N. Xu, J. Xing, X. Meng*; Shanghai/CN*

Purpose: Subtraction CT angiography(CCTA) using a 320-slice CT scanner has recently been introduced for patients with severe calcifications. Subtraction CCTA can remove calcification from CCTA images, and reduce the misevaluation of luminal stenosis degree caused by calcification artefacts. But many patients are unable to finish the scanning protocol due to the long breath-holding time, which limits its clinical application. We explored an optimised subtraction CCTA method with a short breath-holding time. The purpose of this study was to evaluate whether the short breath-Holding time protocol for subtraction CCTA could provide better image quality compared with the conventional CCTA.
Methods and materials: A total of 12 patients with coronary calcifications were enrolled in this study. The optimised subtraction CCTA was performed using the bolus-tracking method. The mask scan was acquired before the postcontrast scan during a single breath-hold. The patients' breath-holding times were recorded. The subtraction image was obtained by subtracting the mask image data from the postcontrast image data. Subjective image quality was evaluated using a 4-point scale.
Results: The mean breath-holding time was 10.12 ± 0.75 seconds (range, 8.9–11 seconds). Average image quality was significantly increased from 2.42 ± 0.67 with conventional CCTA to 3.0 ± 0.43 with subtraction CCTA ($P < 0.05$).
Conclusion: The optimised subtraction CCTA method allows the breath-holding time to be shortened to <12 seconds and provided better image quality compared with the conventional CCTA. The technique may be applied to patients who are unable to perform a long breath-hold and improve the success rate of subtraction CCTA.
Limitations: It is a small sample research up to now. The research is going on.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Very low volume of contrast material in pre-TAVI CT: how low can we get?
P. Olga, A. Wolak, R. Wolff, Y. Almagor, N. R. Bogot*; Jerusalem/IL (olgapich@mail.ru)*

Purpose: To evaluate and compare the image quality of pre-TAVI (transaortic valve implantation) CT protocol of high pitch using weight adapted reduced contrast media (CM) injection vs standard pre-TAVI protocol.
Methods and materials: Retrospective analysis of 117 (73 females) consecutive patients undergoing pre-TAVI CT on Siemens FORCE scanner. 95 patients (mean age 81±7; weight 70kg±13) using FLASH high pitch single combined heart-aorta acquisition. CM volume (Omnipaque350) and injection rate administrated per weight. 23 patients (age 79±9;80kg±24) in the standard protocol control group underwent spiral cardiac scan followed by high pitch aortic acquisition. In both groups, scan was triggered by bolus-tracking. Attenuation values (HU) and contrast-to-noise ratio (CNR) were measured at the aortic root, abdominal aorta and femorals. Image quality considered sufficient at attenuation >200HU.
Results: CM volume and injection rate were significantly lower in FLASH group compared to control group (39±9ml/ 3±0.5ml/sec vs 75±8ml/ 4.2±0.8 ml/sec; $p<0.05$). DLP in FLASH was 303±104 vs 1175±772 in control. Image quality was sufficient in FLASH and control groups respectively: root-89 (93%) vs 19 (82%) of patients, abdominal aorta-94 (99%) vs 20 (87%) and femorals-85 (89%) vs 20 (87%) (P=NS). Non-significant difference in attenuation and CNR found between two groups for root (350±100HU/16 vs 348±256HU/15.6) and abdominal aorta (372±98/HU30 vs 416±257HU/30.5). Significant decrease in femorals attenuation and CNR in FLASH group (301±109HU/23 vs 449±221HU/33; $p<0.05$). Patient weight and DLP were lower in FLASH group ($p<0.05$).
Conclusion: Using single high pitch cardiac-aortic pre-TAVI CT scan with weight-adjusted injection allows significant CM volume and radiation dose reduction with preserved images quality.
Limitations: Single institution study. The standard group was smaller than FLASH group.
Ethics committee approval: Approved by the IRB, informed consent waved.

Heart rate-dependent degree of motion artefacts in coronary CT angiography acquired by a dedicated cardiac CT scanner
M. Vecsey-Nagy, B. Szilveszter, A. Jermendy, M. Kolossvary, J. Simon, Z. Drobni, B. Merkely, P. Maurovich--Horvat*; Budapest/HU (nagy.milan33@gmail.com)*

Purpose: Currently used wide detector CT scanners enable precise assessment of coronary artery disease (CAD). However, no data is available regarding the degree of motion artefacts in images acquired by the recently introduced 560-slice CardioGraphe (CG) scanner. We aimed to assess the heart rate (HR) dependent presence and degree of motion artefacts in coronary CT angiography (CCTA) scans acquired by CG compared to a conventional 256-slice CT scanner.
Methods and materials: In this retrospective study, we have compared the images of 75 patients who underwent CCTA with CG (240 ms rotation time) to 75 scans acquired by a 256-slice CT scanner (270 ms rotation time). The mean age of the groups was 57.3 years, 49.3% males. Motion artefacts were assessed using a Likert-type scale, ranging from 1 to 4 (1: non-diagnostic, 2: severe motion artefacts, 3: mild motion artefacts, 4: no motion artefacts). The patients were divided into 3 equal groups (50-50-50 patients) according to HR ranges during image acquisition (51-60/min, 61-70/min, above 71/min). The image quality of each of the three groups in both scanners was compared using Wilcoxon rank-sum test.
Results: The CG scanner had a better image quality, with reduced motion artefacts as compared to the 256-slice scanner (mean Likert-score 2.7 ± 0.9 vs 2.3 ± 0.7, respectively, $p<0.003$). The CG images had higher Likert-scores in all 3 heart rate ranges (51-60/min, 61-70/min, 71+/min), which was statistically significant in the lower 2 ranges ($p=0.025$, $p=0.043$, $p=.156$, respectively).
Conclusion: The new 560-slice CG scanner allows for CCTA image acquisition with reduced motion artefacts as compared to a 256-slice scanner. The beneficial effect of fast gantry rotation was especially present at HR below 70/min.
Limitations: Not applicable.
Ethics committee approval: Not applicable.
Funding: Not applicable.

Radiological visualisation in the diagnosis of potentially life-threatening conditions of an athlete's pathological heart
B. Sergey[1], V. Sukhov[2], D. Pospelov[2], E. Achkasov[1]; *[1]Moscow/RU, [2]St. Petersburg/RU (sabondarev@yandex.ru)*

Purpose: Frequency of fatal cardiac abnormalities development in athletes resulted in an increase in mortality, which reaches 75%. With the evidence of such dangerous changes development, it becomes extremely important to make an early diagnosis of these.
Methods and materials: We examined 11 male athletes 18-23 yo without significant family history regarding the pathology of cardiovascular system, involved for 14±2 yrs in playing sports with anamnestic presence of chronic physical fatigue and heart pains that underwent clinical examination, biochemical blood tests, ECG, stress-echocardiography, 12-leads Holter-monitoring, myocardial scintigraphy with 123I-MIBG, 99mTc-tetrofosmin rest/stress SPECT and, gadolinium-enhanced MRI.
Results: Biochemical markers of cardiomyocytes' acute damage were concordant to the clinical significance of these disorders matching to complaints severity of cardiac arrhythmias. Along with these data no violations of morphology, size and function of myocardium were revealed. Results of myocardial SPECT, stress ECG-test, stress echocardiography, daily Holter monitoring had no signs of myocardial ischemia. We didn't have laboratory and other data for inflammatory myocardial damage. Early phase 123I-MIBG scintigraphy (15' p.i.) showed impaired tracer accumulation in apex, anterolateral and inferior walls down to 61-67%. In the delayed phase (240' p.i.) less significant decrease of radiopharmaceutical uptake was noted. Diffuse-focal decrease of tracer uptake by myocardial perfusion SPECT with 99mTc-tetrofosmin not exceeding 8% of LV was noted in the anteroseptal region with improvement after the physical exercise test.
Conclusion: The combined use of diagnostic methods, such as SPECT, CE-MRI, stress echocardiography, make it possible to carry out differential diagnosis, to exclude acute coronary insufficiency, acute inflammatory damage of heart, regarding changes as a variant of takotsubo syndrome.

Limitations: This study is limited by its sample.
Ethics committee approval: All patients provided informed consent for examination, treatment, data processing and use of data in scientific work.
Funding: No funding was received for this work.

Relationships between coronary atherosclerotic morphology of computed tomography coronary angiography and myocardial perfusion abnormalities

A. Maltseva, K. W. Zavadovsky, A. Mochula, K. Kopeva, E. Grakova*; Tomsk/RU (maltseva.alina.93@gmail.com)*

Purpose: The purpose was to assess the relationships between morphological CT-characteristics of coronary atherosclerosis and myocardial perfusion downstream in patients with an intermediate pretest probability of stable coronary artery disease (SCAD).
Methods and materials: The study group comprised 68 patients (42 men, age 63 (56;68) years) who underwent coronary computed tomography angiography (CCTA) as well as stress-rest MPI (with CT attenuation correction) on the hybrid system GE Discovery NM/CT 570C. The patients were divided into two groups: 1) moderate and large stress perfusion defect extent (SSS≥9); 2) small perfusion defect extent (SSS<9).
Results: According to the univariate logistic regression, maximum stenosis (OR 1,04; CI 1,02-1,06; p=0,0001), the sum of stenoses (OR 1,01; CI 1,00-1,01; p=0,02), Segment Stenosis Score (OR 1,14; CI 1,04-1,25; p=0,04) and CT_SS (OR 1,32; CI 1,12-1,56; p=0,01), the presence of stenosis >50% (OR 5,4; CI 1,69-17,16; p=0,004), noncalcified (OR 1,79; CI 1,11-2,87; p=0,017) and circular features (OR 2,99; CI 1,48-6,04; p=0,002) of the atherosclerotic plaques were the independent determinants of moderate and large perfusion defect. By the results to multivariable logistic analysis the combination of several CT-characteristics of coronary atherosclerosis did not improve the prognostic model.
Conclusion: Segment Stenosis Score, CT_SS as well as the noncalcified structure and circular geometry of the atherosclerotic plaques are the most significant independent predictors of moderate and large stress perfusion defects. These CT morphological characteristics could be used for risk stratification in patients with an intermediate pretest probability of SCAD.
Limitations: This is the relatively small size of the study population.
Ethics committee approval: The local research ethics committee approved this study.
Funding: No funding was received for this work.

Aortic valve calcification scoring with computed tomography: the impact of advanced modelled iterative image reconstruction

R. M. M. Hinzpeter, F. Maisano, A. M. Kasel, F. Tanner, H. Alkadhi, M. Eberhard*; Zurich/CH (Ricarda.Hinzpeter@usz.ch)*

Purpose: To investigate whether advanced modelled iterative reconstruction (ADMIRE) of CT scans affects aortic valve calcification (AVC) scoring and likelihood categorisation of severe aortic stenosis.
Methods and materials: In this IRB-approved retrospective study, we included 100 consecutive patients with symptomatic aortic stenosis (median age: 77 years; 39 females) undergoing CT prior to transcatheter aortic valve replacement between 03/2019 and 10/2019. CT scans dedicated to calcium scoring were performed according to current guidelines and reconstructed with filtered back projection (FBP) and ADMIRE at strength levels 1-5. AVC Agatston scores were evaluated using a commercially available software platform. Gender-specific AVC Agatston score cut-off values were applied according to the current European Society of Cardiology recommendations to assign patients to different likelihood categories of aortic stenosis (unlikely to very likely). AVC scores are shown as median and interquartile-range (IQR). Friedman test was applied to analyse interval- and ordinal-scaled data.
Results: Each reconstruction algorithm produced statistically significant numerical AVC Agatston scores (p<0.001). Median AVC Agatston score for image reconstruction with FBP was 2527 (IQR: 1602-3673) and decreased with increasing ADMIRE strength levels. Image reconstruction with ADMIRE at strength level 5 showed the lowest median AVC Agatston score (2281, IQR: 1357-3362). Likelihood categorisation of severe aortic stenosis was significantly different between image reconstruction algorithms (p<0.001). For image reconstruction with FBP, 55 cases were assigned to the “very likely” category, compared to 44 cases performing image reconstruction with ADMIRE at strength level 5.
Conclusion: Image reconstruction of CT scans dedicated to AVC scoring with ADMIRE causes a significant decrease of AVC scores with increasing ADMIRE strength levels and therefore affects likelihood categorisation of severe aortic stenosis.
Limitations: This study is performed in a single-site, one vendor.
Ethics committee approval: The IRB approved, written informed consent obtained.
Funding: No funding was received for this work.

Histological validation of cardiac magnetic resonance T1 mapping for evaluation the variation in myocardial infarction on day 1, day 7 and 3 months in a swine model

L. Zhang, Y. Guo, H. Xu, M. Yang, R. Xu, Z. Yang, C. Fu*; Chengdu/CN (zhanglu_scu2018@163.com)*

Purpose: Our aims were to explore 1) how native T1 and extracellular volume (ECV) measured on CMR changed with time in infarcted myocardium; 2) the correlation between ECV and native T1 against histology-evaluated ECV.
Methods and materials: A total of 22 pigs were subjected to occlude anterior descending artery and underwent serial CMR examinations at acute (within 24h, n = 22), subacute (7 days, n = 13) and chronic (3 months. n = 6) after myocardial infarction (MI). The CMR protocol included cine, Modified Look-Lock Inversion (MOLLI) recovery and late gadolinium enhancement (LGE). Hematoxylin-eosin and Masson trichrome staining were conducted following scanning. The CMR exams and histopathological staining were performed in the same day.
Results: Infarcted native T1 changed with peaking at 7 days while a progressively increasing was observed in ECV during 3 months. The histology-evaluated ECV demonstrated a well correlation in the comparison with native T1 (acute, $r = 0.89$, $p < 0.001$; subacute, $r = 0.94$, $p < 0.001$; chronic, $r = 0.83$, $p < 0.001$); Also, a high correlation was found when compared with CMR-measured ECV (acute, $r = 0.89$, $p < 0.001$; subacute, $r=0.96$, $p < 0.001$; chronic, $r = 0.82$, $p < 0.001$).
Conclusion: Both native T1 and ECV in infarcted myocardium demonstrated dynamical changed with time. This may be explained by the severe interstitial oedema and the progressive collagenous deposition. These results have implication for the timing of CMR imaging early after MI.
Limitations: The experimental setup did not allow for baseline examination and early imaging after MI.
Ethics committee approval: This study was approved by the institutional ethics review board.
Funding: No funding was received for this work.

Evaluation of image quality and radiation dose with prospective ECG-gated 80-slice CT angiography, in 182 consecutive children examinations with congenital heart disease

P. de Cambourg, P. Guérin, H. Necib, K. Warin Fresse; *Nantes/FR*

Purpose: Computed tomography angiography (CTA) is a reliable imaging tool to evaluate children congenital heart disease (CHD) but requires radiation exposure. This study aims to investigate image quality and radiation dose with a prospective electrocardiogram (ECG)-gated 80-slice CTA, in 182 consecutive children examinations with CHD.
Methods and materials: 182 consecutive examinations performed with a prospective ECG-gated 80-slice CTA from March 2016 to December 2017 in Nantes university hospital were retrospectively analysed. Radiation dose was assessed by dose length product (DLP) and effective dose (E). The objective quality image was assessed by contrast to noise ratio (CNR) and subjective quality image by two radiologists with a 10-point scale evaluating visualisation of coronary arteries. Correlation between quality image, radiation dose, age, weight, heart rate was analysed.
Results: DLP and E were 29.3±15.5mGy.cm and 0.6±0.2mSv respectively. Agreement between radiologists for subjective image quality was 0.79. Subjective image quality score was significantly better ($p<0.01$) with higher age, weight, DLP and lower heart rate in univariate analysis. CNR was significantly lower with increasing weight and DLP ($p<0.05$) but there was no correlation between CNR and age and heart rate.
Conclusion: Prospective ECG-gated 80-slice CTA is performing for the evaluation of children CHD with good image quality and low radiation dose. Visualisation of small structures is better when age and weight increase, heart rate decreases and when the radiation dose is more important. CNR evolves in the opposite side to subjective image quality score. It seems less appropriate to assess image quality from the clinical view of the radiologist.
Limitations: The study is retrospective.

Myocardial extracellular volume assessment in a cohort of oesophagal cancer patients using routine contrast-enhanced CT

D. Capra, C. B. Monti, C. Gumina, A. Luporini, F. Lombardi, E. Asti, L. Bonavina, F. Sardanelli, F. Secchi; *Milan/IT (davide.capra@unimi.it)*

Purpose: To reproduce the feasibility of estimating myocardial extracellular volume fraction (ECV) through routine contrast-enhanced computed tomography (CT) in a cohort of oesophagal cancer patients and to investigate the correlation between an increase in ECV and exposure to radiation therapy.
Methods and materials: After ethics committee approval, patients with oesophagal cancer who had undergone routine CT examinations before and after radiation therapy were retrospectively analysed. For each patient, we considered pre-treatment CT and the post-treatment CT with the longest follow-up interval available. Patients with pre-existing cardiovascular conditions, who previously had undergone cardiotoxic chemotherapy, or with heavily artefacted CT images were excluded. ECV was measured using round regions of interest (ROI) in the septum at mid-level, accounting for movement by excluding borders, and in the left ventricular blood pool at the same level. Septal ECV was calculated using the formula proposed by Bandula et al. T-test for paired data was used to compare distributions.
Results: Twenty-one subjects were analysed, with a mean age of 64±18 years, four of which were women. Pre-treatment mean ECV was 27.89±3.54% and post-treatment mean ECV at follow-up was 32.08±4.51% with a median interval of 197 days. Post-treatment ECV was significantly higher than pre-treatment ECV ($p<0.001$).
Conclusion: ECV in oesophageal cancer patients showed to be significantly higher after treatment. Its rise after radiation therapy could play a role in the screening of myocardial condition in oesophageal cancer patients undergoing such treatment.
Limitations: This study is limited by its small sample size and its retrospective, monocentric nature.
Ethics committee approval: Ethics committee approval was obtained. Written informed consent was waived.
Funding: No funding was received for this work.

Preclinical multimodal imaging for a new theranostic approach in oncology

M. Gulizia, J. N. Hyacinthe, O. Lorton, L. A. Crowe, R. Salomir*; Geneva/CH*

Purpose: In the framework of developing theranostic nanotechnology in oncology, we develop and optimise methods to improve local deposition of PFOB nanodroplets in tumours using high-intensity-focused ultrasound (HIFU). We optimised a multimodal imaging pre-clinical protocol to evaluate the efficacy of HIFU modulated accumulation of nanodroplets in tumours.
Methods and materials: We compared treatment and control groups. We grafted tumour 4T1 cells subcutaneously. We injected retro-orbital 300 µl of PFOB. HIFU treatment was performed after injection and guided with MRI. We used MR-thermometry for the temperature control induced by HIFU. The PFOB was analysed with 19F-MRI and fluorescence imaging. We compared concentrations 1 and 24 hours post-treatment to evaluate the efficacity of the HIFU.
Results: The treatment group presented with higher concentrations of PFOB in the tumour. We used a Mann-Whitney U test. P=0.0339 (alpha 0.05). HIFU treatment probably increased the PFOB deposited in the tumour. The MR thermometry sequence was sufficient for this control. The 19F MRI sequence qualitatively showed colocalisation of fluorine in the tumour but was not quantitative enough. Fluorescence imaging allowed quantification of PFOB.
Conclusion: We demonstrated the feasibility of a mechanical HIFU procedure to significantly increase the local deposition of PFOB nano-emulsion in tumours. This work opens promising perspectives for developing a theranostic approach in oncology. The means of control are sufficient for this study.
Limitations: The limited sample size.
Ethics committee approval: In vivo experiments have been conducted under the Swiss law for animal experimentation [Art.18 (LPA), Art.141 (OPAn), Art.30 Ordonance sur l'expérimentation animale]. Experimental protocol has been evaluated and approved by the cantonal veterinary office of [GE/140/1].

Multimodal and theranostic iodinated-porphyrins contrast agents: synthesis, x-ray attenuation, and cytotoxicity evaluation

R. M. S. C. Pereira[1], C. Luis[2], M. D. G. P. M. S. Neves[1], R. Fernandes[2], M. D. A. F. Faustino[1]; *[1]Aveiro/PT, [2]Porto/PT (ruimpereira@ua.pt)*

Purpose: Porphyrins, due to their chemical, photophysical, and biological properties, could conjugate in a single molecule; drug properties with multimodal and/or theranostics applications. Such properties can be an excellent answer to the challenging demand of novel contrast media acting as multimodal and theranostic agents (MTCA). Those type of compounds were already studied in magnetic resonance (MRI) and near-infrared fluorescence imaging, but very few studies were developed in iodinated contrast media. Our aim was to develop new iodinated-porphyrin contrast agents with suitable x-ray beam attenuation and low toxicity, which can potentially be used as MTCA.
Methods and materials: Iodinated-porphyrin derivatives were prepared through 3 synthetic approaches. X-ray beam attenuation was assessed measuring Hounsfield units (HU) after compound exposure to a standardised computed tomography scan. Cytotoxicity was assessed in 3 cell lines exposed to the new iodinated-porphyrins derivatives using the MTT cellular viability assay. Results were internally compared with iomeprol, a contrast agent already on the market.
Results: 12 stable iodinated-porphyrin derivatives were successfully obtained with moderate to good yields. All compounds showed an x--ray beam attenuation ability similar to iomeprol (iomeprol: 488.2±1.2 HU; compounds: min-Por7 with 461.2±2.5 HU; max-Por4 with 483.5±2.6 HU). 7 of the iodinated-porphyrin derivatives showed similar viability to iomeprol, although only Por1 and Por2 presented better IC_{50} than iomeprol.
Conclusion: All synthesised compounds showed a proper x-ray beam attenuation ability to been used as contrast media. Por1 and Por2 (the last one with multimodal properties) showed decreased cytotoxicity when compared with iomeprol. Also, Por5, Por11, and Por12 showed promisor cytotoxicity evaluation results.
Limitations: Only toxicity in the dark was evaluated.

Iodinated contrast media and their effect on thyroid function: routines and practices among diagnostic imaging departments in Norway

A. Rusandu, B. Sjøvold, E. Hofstad, R. J. Reidunsdatter*; Trondheim/NO (albertina.rusandu@ntnu.no)*

Purpose: In order to minimise adverse effects or injuries related to the effect of iodinated contrast media (ICM) on the thyroid, international guidelines recommend developing routines for the identification and management of patients at risk of developing thyroid dysfunction. This study aimed to investigate thyroid-related ICM administration routines among diagnostic imaging departments in Norway.
Methods and materials: A cross-sectional survey including 24 hospitals and 75 respondents (37 radiographers and 15 radiologists) with a 69% response rate was conducted. The survey covered routines for assessment and the management of risk-patients and rationale for the routines.
Results: The findings show a variation in routines among hospitals. The use of checklists as recommended by international guidelines was quite modest (15%), the respondents preferred other methods to identify risk and contraindications. Only 20% reported checking for scheduled thyroid scintigraphy or radioactive iodine therapy. 42% did not have thyroid-related ICM routines and the main reported reason was a lack of knowledge on the topic. Radiographers and radiologists expressed uncertainty about each other's roles and routines.
Conclusion: This study revealed the need for optimisation of routines regarding ICM administration to thyroid-related risk-patients. Training courses and activities that improve the interprofessional network might facilitate effective implementing of the guidelines.
Limitations: The low number of participant radiologists, which might reduce the precision of estimate and mask potential significant differences between the occupational groups.
Ethics committee approval: The Regional Committee for Medical and Health Research Ethics waived the need for approval as the project was considered a quality assurance project which did not involve any health-related or personal information. Participants were informed about the purpose of the study and that submitting the survey was regarded as implied consent.
Funding: No funding was received for this work.

A statistical comparison of a triage tool with exercise myocardial perfusion scan (MPS) data in a cohort of Maltese patients

K. Borg Grima[1], P. Bezzina[2], L. A. Rainford[3]; *[1]Naxxar/MT, [2]Malta/MT, [3]Dublin/IE (karen.borg-grima@um.edu.mt)*

Purpose: To investigate whether the results of a pre-determined triage tool recorded a statistically significant relationship with MPS results. The triage tool had been designed to assist in identifying patients who might not achieve the necessary exercise level.
Methods and materials: The triage tool was composed of 11 clinical questions and was used to collect data from 300 patients referred for MPS exercise stress testing in the state general hospital in Malta. Data was collected from March-June 2018. Scan data included the duration of exercise stress tests, results of the Duke treadmill score, summed stress score (SSS), and the total perfusion deficit (TPD).
Results: The tool demonstrated statistical significance in identifying patients who had a reduced functional ability, therefore being incapable of successfully completing their MPS treadmill exercise stress test. Gender (p<0.001), chest

pain when walking uphill (p<0.001), and the presence of previous revascularisation procedures (p=0.015) were all found to be statistically related to the treadmill exercise test duration. Moreover, a statistical significance was found between the triage tool results and the results of the DTS (p<0.001), SSS (p=0.048), and the TPD (p<0.001) scores.
Conclusion: The findings of the study identified that out of 82 participants who had a positive triage tool result, 93.9% had an inconclusive exercise stress test, confirming the value of this tool as a means of triaging patients prior to undergoing MPS exercise stress tests.
Limitations: The sample of participants was taken over a specific period of time, therefore further research is recommended to collect data prospectively over a longer timeframe.
Ethics committee approval: This study was performed following ethical permission from the University of Malta Research Ethics Committee.
Funding: No funding was received for this work.

The optimisation of computed tomography dose levels in ^{18}F-FDG PET-CT oncology examinations
R. A. F. Nunes, J. M. T. E. Rio, J. Santos*; Coimbra/PT (nunesritafa@gmail.com)*

Purpose: To evaluate CT dose values used on PET-CT with ^{18}F-FDG for oncology examinations and to optimise the institution practices in order to reduce patient exposure.
Methods and materials: The study was carried out in two phases. A retrospective phase, phase 1, analysed the clinical practice based on CT dose descriptors, acquisition parameters, and the influence of arm position on whole-body PET-CT protocols with ^{18}F-FDG on Philips Gemini GXL 16 and Siemens Biograph 6 equipment. Diagnostic reference levels (DRL's) were established per CT scanner. During phase 2, several protocols were tested on a PBU-60 anthropomorphic phantom in order to analyse the dose reduction in comparison to the current protocol. Objective image quality analysis was performed based on regions of interest.
Results: The obtained DRLs were in accordance with the literature. Significant differences were founded in examination dose values performed with different patient arm positioning. Significant differences were also founded in CT dose values per equipment PET-CT scanner using the same protocol.
Conclusion: This study contributed to the harmonisation of the procedures of ^{18}F-FDG PET-CT in oncological patients. Experimental tests revealed the potential for optimisation with a lower impact on image noise.
Limitations: The experimental tests were similar, however, the PET-CT equipment technology differences didn't allow the testing of the exact the same protocols.
Ethics committee approval: Ethical approval was obtained from the institution.
Funding: No funding was received for this work.

An assessment of mobile radiography services in nursing homes using the model for assessment of telemedicine applications
E. Kjelle, K. B. Lysdahl, A. M. Myklebust, H. M. Olerud*; Kongsberg/NO (elin.kjelle@usn.no)*

Purpose: To assess mobile radiography services in nursing homes using the model for assessment of telemedicine applications (MAST).
Methods and materials: As MAST is a multidisciplinary assessment, multiple methods were used. Six out of 7 domains in MAST was assessed. A systematic literature review and statistical analysis were used to assess the following domains: (1) health problem and description of the application, (2) safety, (3) clinical effectiveness, and (4) patient perspectives. Cost-analysis using a decision-model was used for assessment of (5) economic aspects. Individual semi-structured interviews were used to assess (6) organisational aspects.
Results: Mobile radiography services were found to be safe with adequate image quality and the examinations affecting treatment and care (domains 1-3). The number of examinations was significantly higher in areas with mobile radiography; 0.5 per nursing home beds compared to 0.36 without this service; p=<0.001 (domain 1). The treatment given became more personalised when an examination was made in the nursing home. Patients and their relatives prefered mobile radiography (domain 4). In domain 5, mobile radiography was found to reduce costs by 30% compared to hospital-based services, a significant difference; p=<0.001. Managers experienced a need for organisational change when implementing mobile radiography (domain 6).
Conclusion: A mobile radiography service is a safe, high-quality telemedicine service, which contributes to increasing the quality of care and reducing costs. However, to facilitate a full-scale implementation of these services, there seems to be a need for changing the way health services are funded and managed.
Limitations: This PhD-project on mobile radiography services was mainly assessed in a Norwegian context, limiting its transferability.
Ethics committee approval: Approved by REC - project no. 2468. Approved by NSD - ref. 45739
Funding: No funding was received for this work.

RPS 1714-7 09:06
Consideration of anatomical side markers by radiographers and student radiographers
L. A. Rainford, J. M. Grehan, M. O'connor, J. G. Stowe, M. D. Davis, E. McDermott, R. Toomey*; Dublin/IE (louise.rainford@ucd.ie)*

Purpose: The advent of digital radiography facilitated the easy addition of digital anatomical side markers to medical images, however, this is not considered best practice. Reported here is a subset of a larger study investigating how qualified medical doctors, radiographers, and students review image quality in general, with a particular focus on the importance of anatomical side markers.
Methods and materials: The research participants were 57 qualified radiographers and 65 student radiographers who volunteered at the EFRS Research Hub 2019 . They completed an image-viewing task whereby they reviewed 26 projection radiographs and decided if the images were ready to be sent to the PACS system for reporting. They could respond: a) optimal=send to PACS, b) acceptable=but could be improved, and c) unacceptable=action required before sending. They were not prompted to consider side markers or any other factors in particular. 8 images had no side marker, 7 had a digital marker, and 11 a lead marker.
Results: Participants rated 21.71% (qualified)/23.27% (students) of images with no marker as optimal, with a further 38.6%/39.42% rated "acceptable", implying that 60.31%/62.69% of images would be sent to PACS without a marker. 32.75% of images with a digital marker were rated "optimal=send to PACS".
Conclusion: Radiographers may underestimate the importance of anatomical side markers and further research is warranted.
Limitations: Selection bias; participants were present at ECR and therefore may be more research/professionally active. Participants from some countries/institutions may be overrepresented. Language may have inhibited understanding of the task in participants without English as a first language.
Ethics committee approval: The home institution Human Research Ethics Committee declared the work exempt from full review.
Funding: No funding was received for this work.

Radiographer optimisation of AEC use: keeping it "automatic" but taking back "control"
K. Matthews, J. Creedon, A. Dalton, E. Higgins, R. Motyer*; Dublin/IE (kate.matthews@ucd.ie)*

Purpose: This presentation reports 4 separate but associated studies which shared the common aim of establishing whether the use of automatic exposure control in direct digital radiography could be better optimised in some Irish hospitals.
Methods and materials: Various phantoms (PIXY without and with added layers of fat; ATOM paediatric phantoms age 1,5, 10, and 15) were x-rayed in 3 hospitals to simulate chest, pelvis, and lumbar spine radiography. AEC settings such as patient size and system speed were varied in order to change the dose constant controlling the AEC. The dose area product (DAP) and exposure index (EI) were recorded. Selected images were evaluated; noise levels were measured through the calculation of the signal-difference-to-noise ratio (SDNR) and the visual image quality was assessed through a visual grading analysis

(VGA). At each site, all measurements were compared with those obtained at prevailing clinical exposures.
Results: Radiographers can manipulate the AEC dose constant using the patient size and system speed selections. Such manipulations produced considerable (up to 54%) reduction in DAP. While DAP and SDNR values decreased with reduced AEC dose constant, the visual image quality as appraised by VGA was preserved to a point, demonstrating the maintenance of diagnostic image quality. The dose and image quality data from these phantom experiments showed consistent findings across examinations representing adults, obese adults, and children.
Conclusion: For the examinations tested, the dose constant programmed into the AEC in all sites results in an unnecessarily large dose.
Radiographers can and should manipulate the AEC settings to control automatic exposure and thus better optimise examinations.
Limitations: A phantom study is appropriate to this experimental research. The findings justify further investigation of AEC manipulation during patient examinations with an evaluation of clinical images.

RPS 1714-9 09:18
The effect of non-optimal tube voltage on radiation dose in lumbar spine radiography
E. Alukić, N. Mekis*; Ljubljana/SI*

Purpose: To investigate how exposure parameters or, more precisely, the tube voltage affects radiation dose to the patient in lumbar spine imaging.
Methods and materials: The data for patient weight, height, image field size, and DAP were collated for 100 patients that were referred for lumbar spine radiography on 2 different x-ray units. The first unit used the tube voltage in line with the European guidelines (79kV) while the other unit's tube voltage was not in line with the EU guidelines (63 kV). The data was collected only for the AP projection. After the data collection, the calculations of BMI, effective dose, and dose to selected organs were calculated using a PCXMC2.0 Monte Carlo simulation program.
Results: No statistically significant difference was found between the BMIs of the compared groups (p=0.671). When the optimal exposure parameters were used, the DAP value was lower by 79% (p<0.001), the effective dose by 62% (p<0.001), and the average dose to the organs by 73% (p<0.001). The image field was significantly larger when the optimal parameters were used. Therefore, the dose difference should be even higher when the optimal exposure parameters were used if the field size would be the same.
Conclusion: Based on the results, we can conclude that the DAP, effective dose, and dose to organs are significantly higher when the exposure parameters used are not in line with the European guidelines.
Limitations: The data was obtained for AP projection only and the image quality was not assessed in the study.
Ethics committee approval: The national medical ethics committee and patient consent form were obtained prior to the study.
Funding: No funding was received for this work.

The optimisation of the lateral lumbar spine projection using an air-gap technique
A. Bellizzi, F. Zarb*; Msida/MT (andrea.bellizzi.15@um.edu.mt)*

Purpose: To investigate the feasibility of replacing an anti-scatter grid with an air-gap technique to achieve a dose reduction for lateral lumbar spine radiography while maintaining image quality on a direct digital radiography (DDR) system.
Methods and materials: The study comprised of 2 phases. Phase 1 was an experimental study using an anthropomorphic phantom to identify the optimal air-gap technique. Phase 2 was performing lateral projections of the lumbar spine on patients (n=50). Patients were randomly assigned into a control group (n=25, imaged using the anti-scatter grid) and an experimental group (n=25, imaged using the air-gap technique). The dose area product (DAP) of all examinations was recorded, keeping all other variables constant. Image quality evaluation was performed by 5 radiologists performing absolute visual grading analysis (VGA) using an image quality score tool, with the resultant scores analysed using visual grading characteristics (VGC).
Results: A 10 cm air-gap in conjunction with a source-to-image distance (SID) of 121 cm was found as the optimal air-gap technique. The clinical application of this technique resulted in a statistically significant (p<0.05) reduction in the radiation dose of 72% in terms of DAP. Image quality scores were higher for the anti-scatter grid but the variation between the image quality of the two techniques was not significant (p>0.05).
Conclusion: The results imply that replacing the anti-scatter grid with an optimal air-gap technique in lateral lumbar spine digital radiography provides a significant dose reduction whilst still maintaining diagnostic image quality.
Limitations: Differences in lateral thickness was a variable, limited by matching mean thickness for both groups. More air-gap/SID combinations were available, but particular distances were due to the physical room limitations.
Ethics committee approval: Approval obtained from the University of Malta Research and Ethics Committee.
Funding: No funding was received for this work.

RPS 1714-11 09:30
The influence of optimal collimation on radiation dose and image quality in thoracic spine radiography
A. Pažanin[1], D. Škrk[2], N. Mekis[2]; [1]*Dubrovnik/HR,* [2]*Ljubljana/SI (apazanin@gmail.com)*

Purpose: To determine the change of radiation dose to the patient and impact on image quality when the collimation referred to in the professional literature is used for thoracic spine radiography.
Methods and materials: The study was performed on 84 patients who were referred for thoracic spine radiography in a Croatian hospital using a CR imaging system. Patients were randomly divided into 2 equal groups. The first group was imaged with the current collimation protocol and the second group with the collimation protocol mentioned in the professional literature. For each patient, weight and height, image-field size, exposure conditions, and DAP were measured while the effective dose and absorbed organ doses were calculated using the PCXMC Monte-Carlo simulation method. Image quality was assessed by 2 radiologists and 1 radiographer using the image software ViewDEX.
Results: There was no statistically significant difference in BMIs between the groups. With the optimal usage of collimator, it was found that the size of the primary field in the AP projection was reduced by 45% (p<0.001) and in the LAT projection by 41% (p<0.001). The study also showed reduced values of DAP for AP projection by 34% (p=0.007) and for LAT projection by 23% (p=0.040). The effective dose was reduced by 54% (p<0.001) for AP projection and 29% (p<0.001) for LAT projection. The mean absorbed dose to selected organs decreased by 26% in the AP projection and 28% in the LAT projection. Image quality evaluation showed improvement in AP projection by 13% (p=0.001) and in LAT projection by 15% (p<0.001).
Conclusion: Optimal collimation in thoracic spine imaging has a strong influence on the reduction of patient exposure to radiation and the improvement of image quality.
Limitations: n/a
Ethics committee approval: Ethics committee approval obtained.

RPS 1714-12 09:36
Automating a generic performance assessment of plain radiography imaging systems
R. Us, N. Mekis*; Ljubljana/SI (rok3us@gmail.com)*

Purpose: To produce a transparent algorithm with the capacity to quickly and cheaply measure the relative performance of plain radiography imaging systems (IS).
Methods and materials: We used an ETR-1 test plate in combination with several plain radiography IS based on both CR and DR detector technology. We collected 20 radiographs for each focal spot (FS) setting using every IS. The test plate was placed at 20 mm intervals along the z-axis in order to reveal the potential impact of the anode heel effect and focal effect on image quality. We used exposures of 0.5 mAs at 81 kVp in order to avoid noise elimination and saturation. We upgraded our pilot FIJI macro to include affine image transformation functionality and DICOM header interaction. The macro was used to carry out the consistent characterisation of ETR-1's line-pair segments. This data was exported to a series of spreadsheets which were subjected to

percentile-based formatting as well as an absolute threshold. We also compared equivalent data points belonging to different FS sizes using subtraction.
Results: Our results take the form of 1 spreadsheet for each combination of IS and FS setting, containing contrast maintenance values for 20 different spatial frequencies belonging to each exposure. Percentile-based formatting revealed a deterioration of image quality at the margin of every FOV. This effect was more pronounced on the anode side. Threshold implementation revealed minimum levels of contrast at spatial frequencies consistent with each datasets' respective IS limiting spatial resolution. Subtraction revealed that larger FS produce lower quality radiographs.
Conclusion: Our upgraded FIJI macro appears to possess the capacity to produce useful and accurate assessments of image quality in plain radiography.
Limitations: Only one set of exposure conditions was used.
Ethics committee approval: n/a
Funding: No funding was received for this work.

RPS 1714-13 09:42
Exposure factors selection: a new model for patients with obesity in projection radiography
S. J. M. Alqahtani, K. Knapp, J. R. Meakin, R. M. Palfrey*; Exeter/UK (sa512@exeter.ac.uk)*

Purpose: High radiation doses and dose variations when imaging obese patients are reported in the literature. This is of concern, especially with the high prevalence of obesity. This study reports new exposure factor prediction models that can be implemented in digital radiography.
Methods and materials: Dose optimisation experiments were conducted using a factorial design method. 5 bespoke phantoms with different sizes were used along with a Multi Fusion Max Siemens unit. Image quality was assessed physically and visually, and the DAP used as the dose measure. A mAs prediction model was produced based on the exposure factors (kVp, SID, and filtration) of images with the highest FOM. The data was analysed using Minitab software.
Results: Fixed kVp (75) with 125 cm of SID and 0.3 mm filtration of Cu were observed to produce the best image quality with the lowest dose across all phantoms. The mAs best prediction model was created based on fixed kVp, SID, and filtration with r^2=98.
Conclusion: The results of the current study prove a promising future for image quality improvement in obese patients. A mAs prediction model can be used as a preliminary guide to optimising image quality and minimising radiation dose in obese patients. More studies need to be conducted using other CR and DR systems.
Limitations: Only one digital system was used and the study focused on lumbar spine radiograph.
Ethics committee approval: No ethical approval was needed.
Funding: The PhD fund through Najran University.

RPS 1714-14 09:48
The optimisation of DR chest x-ray images using artificial intelligence: a pilot study
G. de Vries[1], A. England[2], H. Bijwaard[1], A. van der Heij-Meijer[3], P. H. Hogg[2]; *[1]Haarlem/NL, [2]Salford/UK, [3]Groningen/NL (geert.devries@inholland.nl)*

Purpose: Contemporary approaches to optimisation often involve physical phantoms which represent human anatomy. Images are analysed using mathematical techniques. Inferences are then made to predict whether abnormalities would be visible in human images. Such approaches have limitations, such as that some abnormalities are not included and phantoms are simple representations of anatomy. We report our initial work to determine whether artificial intelligence (AI) can be used in dose optimisation with anthropomorphic phantoms containing abnormalities.
Methods and materials: A deep convolutional neural network (DCNN) was trained on human chest x-ray images. PBU-60 anthropomorphic chest phantom images with synthetic nodules at 5 different locations and a 'no nodule condition' were acquired using 65kVp-125kVp in 10kVp steps; mAs was set to automatic exposure control (AEC) level, quarter, half, double, and four times AEC. SID was 200 cm. For each nodule condition, 4 phantom thicknesses were used: 0 cm, 2.5 cm, 5 cm, and 7.5 cm of PMMA. ROC area under the curve (AUC), sensitivity, and specificity were calculated from the output probabilities of DCNN for each kVp-mAs combination. Adequate image quality was considered at AUC >0.9, sensitivity>0.9, and specificity>0.6.
Results: For all exposures, >AEC the AUC was ≥0.9. Image quality was adequate for tube load half AEC at 85kVp suggesting possible dose reduction, for AEC at 85-95kVp suggesting mid-range tube potential settings as optimal, and for double AEC at 75-95kVp and four times AEC at 65-105kVp supporting the dose creep phenomenon.
Conclusion: These preliminary results suggest AI has the potential to be used in dose optimisation with anthropomorphic chest phantoms.

Radiographers' practice and the main reasons for the use of fluoroscopy to position patients during conventional radiography procedures
L. Hirschi[1], S. Rey[2], R. Le Coutre[2], M. Champendal[2]; *[1]La Chaux-de-Fonds/CH, [2]Lausanne/CH*

Purpose: To identify if fluoroscopy is used to guide the patients' positioning during conventional radiography procedures in clinical practice and the main reasons to do it.
Methods and materials: A questionnaire was developed, tested, and distributed to radiographers working in radiological departments that collaborated with an educational institution in French-speaking Switzerland. The questionnaire was composed of 32 questions exploring socio-demographic aspects, professional experience, context, and radiographic practice. Descriptive statistics and thematic analysis were performed according to the nature of the questions.
Results: The participation rate was 33% (87/264). From those participants, 39% were using fluoroscopy to guide the positioning of patients that needed radiographs of the spine, knee, and shoulder. They were working mainly in private practice (67%). The main reasons presented to use fluoroscopy were radioprotection, patient size, patient collaboration, previous surgeries, and to achieve a higher level of image quality. The radiographers that were not using fluoroscopy presented reasons as reducing radiation exposure time and dose and that the competence, professional experience, and practice were solid enough to achieve the adequate results to respond to the clinical demands.
Conclusion: In general, radiographers are not using fluoroscopy to guide patient positioning except in contexts that are more challenging, such as non-collaborative patients or after surgeries. It seems that experience and expertise are important aspects to reduce the use of fluoroscopy during radiography examinations. Further work is necessary to identify the limitations and benefits of using fluoroscopy. Radiographers' training to harmonise practice is also important to increase competences and confidence.
Limitations: Only French-speaking Switzerland was included and no evidence was provided to verify which practice (use or non-use of fluoroscopy) is the most appropriated.

Transjugular intrahepatic portosystemic shunt for the treatment of veno-occlusive disease after liver transplantation: a single-centre experience

R. Miraglia[1], I. Petridis[1], L. Maruzzelli[1], C. Cannataci[2], G. Sparacia[1], G. Mamone[1], A. Luca[1]; [1]*Palermo/IT,* [2]*Msida/MT*
(christinecannataci@gmail.com)

Purpose: Veno-occlusive disease (VOD) is a rare and life-threatening vascular disease, usually seen after haematopoietic stem cell transplantation, but reported also in liver transplant (LT) recipients. Treatment is based on the use of supportive measurements (diuretics, paracentesis) or the employment of anticoagulants and profibrinolytic-antithrombotic agents. Recently, the role of a transjugular intrahepatic portosystemic shunt (TIPS) has been proposed in patients not responsive to medical treatment. However, little data is available on the efficacy and long term follow-up. We present our experience in using the TIPS as a treatment for VOD in LT recipients not responsive to medical treatment.
Methods and materials: Retrospectively, charts of all adults LT recipients who underwent TIPS creation in a single-centre, using ePTFE covered stent, from 2004-2019 were reviewed. In 3 cases, TIPS was performed as a rescue treatment for VOD not responsive to medical treatment.
Results: All patients had a histological diagnosis of VOD performed 2, 5, and 6 months after LT, respectively. 2 patients had refractory ascites and 1 had refractory hydrothorax. Technical success of TIPS was obtained in all cases with a significant reduction of the portosystemic pressure gradient (PPG) (baseline PPG 17, 15, and 10 mmHg, respectively, final PPG 7, 5, and 5 mmHg, respectively). No immediate or delayed complications were reported. Clinical success was achieved in all 3 patients. No patients had post-TIPS hepatic encephalopathy. Until today, all patients are still alive and in good clinical conditions with a follow-up of 130, 49, and 27 months, respectively.
Conclusion: In our experience, TIPS creation was associated with good clinical outcome in the long term in LT recipients with VOD not responsive to medical treatment.
Limitations: A small number of patients.

Transitional care for patients with cirrhosis: a multidisciplinary care model for the prevention of complications post-TIPS

C. Li, Y. Xu*; Shanghai/CN (181659616@qq.com)*

Purpose: To evaluate the efficacy of transitional care interventions of multidisciplinary teams for patients with cirrhosis post-TIPS.
Methods and materials: 68 patients who had undergone TIPS were randomly allocated to a control or intervention group. Patients in the control group received conventional care and patients in the intervention group received conventional care combined with transitional care. The compliance behaviour, the incidence of HE and shunt dysfunction, Child-Pugh scores, and ammonia of the two groups were compared at 1, 3, 6, and 12 months post-TIPS.
Results: Repeated measures analysis of variance showed significant group effects from 1, 3, 6, and 12 months post-TIPS for the compliance behaviour scores of the two groups. The intervention group had significantly higher compliance behaviour scores than the control group 1, 3, and 6 months post-TIPS, respectively. The incidences of HE in the intervention group were significantly lower than the control group 12 months after TIPS. The incidences of shunt dysfunction in the intervention group were significantly lower than the control group 12 months after TIPS. The group effects, time effects, and group*time interaction showed no significant difference in Child-Pugh scores and blood ammonia between the two groups.
Conclusion: Post-TIPS transitional care interventions increase the accessibility of patients to scientifically informed nursing, significantly improve patients' compliance behaviour and health, and decrease the incidence of HE and shunt dysfunction.

(jens-peter.kuehn@uniklinikum-dresden.de)

Purpose: Preoperative portal vein embolisation (PVE) increases future remnant liver (FRL) volume before hemihepatectomy. It is critically discussed when PVE fails in patients with early-stage fibrotic/cirrhotic liver diseases. The purpose of this study was to analyse the hypertrophy rate following PVE in different stages of liver fibrosis/cirrhosis.
Methods and materials: In a retrospective review, patients with malignant liver diseases and PVE of the right lobe were selected from our clinical database. All PVEs were realised by ipsilateral access and using the embolic agent n-butyl-2-cyanoacrylate. Computed tomographic volumetry was performed before and 3-6 weeks after PVE to assess the hypertrophy rate of the left lobe. Patients were characterised by the presence of liver diseases using Child-Pugh scores: A) no cirrhosis and B) moderately severe liver disease. The hypertrophy rate was compared to the severity of liver fibrosis/cirrhosis using a Mann-Whitney-Test.
Results: 56 patients with malignant liver diseases, 17 women/39 men, mean age of 64.5±10.3 years, underwent PVE of the right lobe. Patients had the following Child-Pugh scores: A) 41 patients and B) 15 patients. The overall hypertrophy rate was 25.9±25.4%. Hypertrophy rates did not differ significantly between stages of liver diseases: Child-Pugh A) 26.0±27.2% and Child-Pugh B) 21.3±17.4%; p=0.374.
Conclusion: PVE is an excellent approach to induce FLR hypertrophy before hemihepatectomy, not only in patients with no cirrhosis (Child-Pugh A), but also in patients with a moderate fibrosis/cirrhosis (Child-Pugh B).
Limitations: A limited number of patients with parenchymal liver diseases.
Ethics committee approval: The study was IRB approved.
Funding: No funding was received for this work.

Endovascular treatment of congenital portosystemic shunts: a single-centre prospective study

M. D. Ponce Dorrego*; Madrid/ES (mdponcedorrego@gmail.com)*

Purpose: To assess clinical outcomes of endovascular (EV) treatment of congenital portosystemic shunts (CPSS) and establish a classification system for CPSS to guide closure device selection.
Methods and materials: In 15 patients with CPSS (aged 2 days to 21 years, 10 male) referred for EV treatment from 2014-2017, data was collected prior to treatment (age, sex, medical history, clinical and analytical data, urine trimethylaminuria, abdominal ultrasound, and body-CT), at the time of intervention (shunt anatomical and haemodynamic characteristics, device selected, and closure success) and at the postprocedural time points: during hospital stay and at one year (clinical, analytical, and imaging data).
Results: 1 patient was not treated because the shunt was too wide. Treatment was successful in 12 participants. Migration of the device was observed in 2 and acute splanchnic thrombosis in 1. The changes produced were expansion of portal veins (p=0.005), thrombopenia resolution (p=0.131), ammonia normalisation (p=0.003), increased prothrombin activity (p=0.043), decreased GOT, GPT, GGT, and bilirubin (p=0.007, p=0.056, p=0.036, and p=0.013, respectively), and disappearance of trimethylaminuria and regression of liver nodules (p=0.001). Amenorrhea was resolved in 1 patient and acute liver failure in another.
Conclusion: EV closure of CPSS is effective in inducing expansion of the portal branches. No restrictions exist except shunt width. Congenital absence of the portal vein and side-to-side shunts can be treated.
Limitations: Patients are aged between 2 days and 21 years. This can be considered both a limitation (reduced homogeneity of patient characteristics) and strength (results can be extrapolated to patients with no age restrictions).
Ethics committee approval: Procedural informed consent and written consent for inclusion in the study were obtained and the study protocol was approved by the ethics committee.
Funding: No funding was received for this work.

A simple CT-based score model/nomogram for predicting technical success and midterm outcomes in TIPS treatment for symptomatic portal cavernoma

X. Niu[1], Y. Chen[2]; [1]Chengdu/CN, [2]Guangzhou/CN (niu19850519@163.com)

Purpose: To investigate the clinical significance of a CT-based score model/nomogram for predicting technical success and midterm outcomes in transjugular intrahepatic portosystemic shunt (TIPS) treatment for the symptomatic cavernous transformation of the portal vein (CTPV).
Methods and materials: Patients with symptomatic CTPV who had undergone TIPS from January 2011-December 2016 were retrospectively analysed. The CTPV was graded with a 1-5 score based on contrast-CT imaging findings of the diseased vessel. Outcome measures were technical success rate, stent patency rate, and midterm survival. The nomogram was constructed and verified by calibration and decision curve analysis.
Results: A total of 84 patients (50 men, 34 women; mean age, 52.9±14.6 years) were enrolled. Inter-reader agreement of CTPV score was κ=0.83. TIPS were successfully placed in 82% of patients (69/84). The independent predictor of technical success was a CTPV score (odds ratio [OR] 1.91, 95% confidence interval [CI] 0.86, 3.62, P=0.024, AUC=0.90). The independent predictors for primary TIPS patency were a CTPV score and splenectomy (OR 4.12, 95% CI 0.86, 7.67, P=0.034, and OR 3.91, 95% CI 0.62, 6.76, P=0.041, respectively). The survival rates differed significantly between the TIPS success and failure groups. The clinical nomogram was constructed by patient age, model for end-stage liver disease (MELD), and a CTPV score. The calibration curves and decision curve analysis verified the usefulness of the CTPV score-based nomogram for clinical practice.
Conclusion: TIPS should be considered a safe and feasible therapy for patients with symptomatic CTPV. Furthermore, the CT-based score model/nomogram might aid interventional radiologists with therapeutic decision-making.
Limitations: A small, retrospective study.
Ethics committee approval: n/a

Variation of perfusion of the liver in cirrhotic patients undergoing TIPS placement for refractory ascites: a DCE-MRI study

L. Nocetti[1], R. Scaglioni[1], L. Turco[1], C. Caporali[1], M. Bianchini[1], G. Guidi[1], P. Torricelli[1], S. Colopi[2], F. Schepis[1]; [1]Modena/IT, [2]Rubiera/IT (luca.nocetti@gmail.com)

Purpose: Patients with cirrhosis often develop severe complications of portal hypertension such as refractory ascites that can be treated by a transjugular intrahepatic portosystemic shunt (TIPS). By shunting the portal blood supply to the systemic circulation, TIPS makes liver perfusion dependent on the efficiency of the hepatic arterial buffer response. Dual input mono compartment (DIMC) DCE-MRI is an MR perfusion technique useful in quantifying the contribution of the hepatic artery and portal vein to liver perfusion in the basal condition. In this work, we tested DCE-MRI to monitor liver perfusion before and after TIPS placement.
Methods and materials: TIPS procedure and baseline DCE-MRI were performed the same day; post-TIPS DCE-MRI when the patients' conditions were permissive. All the MRI studies were performed on a 1.5T Achieva Philips, 5ch body coil, with 3DSPGR sequence, TR/TE/FA:5ms/1.66ms/15°, matr:256x256, 11 slices 8 mm thk, para-coronal acquisition, 90dyns, 2s/dyn. A bolus of 0.1 mmol/kg Gd-DTPA was injected after 8dyns. ROIs on input vessels and liver contours were drawn by an expert radiologist. After the images conversion to traces concentration, the DIMC model was applied with in-house "FANTASTIC" software. Portal flow rate (PFR), arterial flow rate (AFR), hepatic flow rate (HFR), the arterial fraction (AF), and the mean transit time (MTT) were calculated.
Results: 21 patients (16 males), 63±11 years with cirrhosis and refractory ascites were included. After TIPS placement, a significant reduction of HFR, PFR, and MTT was observed (p<0.0005, p<0.0001, p< 0.0008, respectively), as well as an increase of the AF (p<0.0001). AFR was found increased although not significative (p=0.094).
Conclusion: MR perfusion can be a valid tool to monitor residual liver perfusion in cirrhotic patients undergoing TIPS implant.
Limitations: The need to analyse the relationship with clinical events such as hepatic encephalopathy.
Ethics committee approval: The study was approved by the local ethics committee.
Funding: No funding was received for this work.

Successful right portal vein embolisation with ONYX in oncologic patients with massive hepatic right lobe involvement

A. Borzelli[1], F. Pane[1], A. Paladini[2], F. Amodio[1], E. Cavaglia[1], R. Niola[1]; [1]Naples/IT, [2]Novara/IT (antonio.borzelli@libero.it)

Purpose: To evaluate the feasibility and efficacy of ONYX as embolisation agent in preoperative right portal vein embolisation to induce adequate left liver lobe hypertrophy before extended right hepatectomy.
Methods and materials: 23 patients (mean age 58.3 years; 12 males, 11 females) with a radiological diagnosis (TC/RM) of extensive involvement of the only right liver lobe by cholangiocarcinoma (7), metastases (9), and HCC (16), with an undamaged left hepatic lobe and future remnant liver <30%, in patients with normal liver, and <40% in cirrhotic patients were included. All patients underwent sonographically-guided percutaneous puncture of the portal vein, performed with a 21G Chiba-needle and selective catheterisation of the main right branch and its ramifications with 5 Fr catheter and 2.7 Fr microcatheter. In all cases, we used ONYX-18. All patients underwent a CT scan before the right portal vein embolisation and another CT scan 1 month after it was performed to calculate the total liver volume, tumour volume, future remnant liver, and degree of induced compensatory left lobe hypertrophy.
Results: Technical success was achieved in all patients (23) with complete embolisation of the right portal vein branch. In no cases did we observe reflux of ONYX in the left portal vein branch and no major complications.
Conclusion: ONYX proved to be a safe and effective embolic agent for preoperative right portal vein embolisation, as it allows complete embolisation of right portal branches, even the smaller distal branches, with a very low risk of reflux and higher probability to determine a satisfactory left lobe hypertrophy. It is still very expensive, but we hope that its cost will lower in the future to allow its wider employment.
Limitations: A retrospective and single-institution study.
Ethics committee approval: n/a

Percutaneous closure of portosystemic shunts other than lienorenal shunts in patients with portal hypertension for recurrent hepatic encephalopathy and bleeding

V. H. Ananthashayana[1], A. Mukund[1], Y. Patidar[2], S. K. Sarin[1], C. Ashok[1]; [1]New Delhi/IN, [2]Delhi/IN (drvenk.rdaiims@gmail.com)

Purpose: To determine the feasibility of a percutaneous approach in embolising non-lienorenal variceal shunts secondary to portal hypertension for recurrent encephalopathy and recurrent bleeding.
Methods and materials: We retrospectively evaluated patients from January 2014-August 2019 who underwent percutaneous closure of variceal shunts other than lienorenal shunts secondary to portal hypertension. A total of 15 patients were found to have undergone shunt closure by percutaneous approach as management for recurrent hepatic encephalopathy (14 patients) and recurrent bleeding (1 patient). We assessed the safety, feasibility, procedural complications, and clinical outcomes of each patient.
Results: Shunt closure and variceal embolisation were performed successfully in all patients. Percutaneous access was achieved through a transhepatic, transplenic, and direct paraumbilical approach by ultrasound and fluoroscopic guidance. Periplenic varix embolisation was performed in 5 patients, perigastric varix embolisation was performed in 4 patients, and umbilical varix embolisation was performed in 5 patients. Both mesocaval and perisplenic varix was embolised in one patient. Embolic materials used were N-butyl cyanoacrylate, coil, and vascular plug devices. There were no procedure-related complications.

Conclusion: Percutaneous access for shunt closure and varix embolisation is a simple alternative image-guided procedure in patients with portal hypertension for recurrent hepatic encephalopathy and bleeding.

The safety and efficacy of portal vein embolisation in patients with prior left lateral liver resection

V. van Den Bosch[1], M. F. Schulze-Hagen[1], F. Pedersoli[2], P. Isfort[1], U. Neumann[1], C. K. Kuhl[1], P. Bruners[1], M. Zimmermann[1]; [1]*Aachen/DE,* [2]*Maastricht/NL (vvandenbosch@ukaachen.de)*

Purpose: To investigate the safety and efficacy of right portal vein embolisation (PVE) following a left lateral liver resection.
Methods and materials: In this retrospective study, we included 13 patients without liver cirrhosis, aged 58.7±27.6 years, who were scheduled to undergo staged hepatectomy consisting of resection of liver segments II and III, followed by right-sided PVE and eventually right-sided hepatectomy (segments V-VIII), thus leaving segments IV (±I) as the future liver remnant (FLR). Using standardised multi-phase CT, we determined the total functional liver volume (TFLV) and volume of the FLR before and at 3-4 weeks after PVE. Patient data was retrospectively analysed for peri- and postinterventional complications, especially with regard to liver function, which was assessed by serum levels of albumin, total bilirubin, ALT, and AST pre-PVE, 1-day post-PVE, and 3-4 weeks post-PVE .
Results: The mean TFLV was 1,550cc before PVE and 1,668 cc after PVE. The mean pre-PVE FLR volume was 328cc and the mean post-PVE FLR volume was 505cc, indicating a mean volume increase of the FLR of 69.4±35.0%. The mean FLR/TFLV ratio post-PVE was 30.0% (range: 22.9-43.0%). PVE was successfully performed in all patients without any peri- or post-interventional complications. Although 11/13 patients developed mild transient elevation of AST and ALT after the PVE, values returned to baseline within 4 weeks. Based on FLR hypertrophy and liver function tests, all 13 would have been candidates for the completion of right-sided hepatectomy after PVE, however, since 3 patients were found to have new metastases within the FLR, a total of 10/13 eventually proceeded to surgery.
Conclusion: PVE of the right portal vein is safe and efficacious in patients who previously underwent left lateral liver resection.

Non-invasive assessment of portal hypertension with spectral CT iodine density: a correlation study with HVPG

J. Dong, R. Wang, F. Liu*; Beijing/CN (dongjianradiology@163.com)*

Purpose: To investigate the feasibility of spectral CT iodine density in the evaluation of portal hypertension by correlation with the hepatic venous pressure gradient (HVPG) in patients with liver cirrhosis.
Methods and materials: 31 patients with liver cirrhosis were recruited in this study and all performed 3 phases of contrast-enhanced spectral CT before TIPS, with the HVPG recorded. Multiple regions of interest (ROIs) in liver parenchyma, aorta, and portal vein were selected, and the mean liver parenchymal iodine density (ID) from the arterial phase, venous phase, and delayed phase were recorded. ID of the liver (IDLAP) and spleen (IDSAP) parenchyma for the arterial phase, venous phase (IDLVP), and ID of the portal vein in venous phase (IDPVP) were measured and correlated with HVPG.
Results: No correlation was found between the liver and spleen volume, IDLAP, IDSAP, IDSVP, and IDLVP with HVPG. IDPVP was found to be independently correlated with the HVPG (P<0.01). With the threshold set as 54.3, IDPVP demonstrated 69.5% sensitivity, 62.1% specificity, 72.6% positive predictive value, and 64.7% negative predictive value in the diagnosis of clinically significant portal hypertension (HVPG ≥12mmHg), respectively.
Conclusion: Spectral CT iodine density demonstrates feasibility in the evaluation of clinically significant portal hypertension in liver cirrhosis as a non-invasive imaging modality.
Limitations: The small number of patients in a single clinical centre.
Ethics committee approval: This prospective study had hospital institutional review board and ethics committee approval.
Funding: No funding was received for this work.

3D/2D-fusion of preprocedural multi-detector-computed-tomography and intraprocedural fluoroscopy for the guidance of portal vein puncture during transjugular intrahepatic portosystemic shunt placement

T. Meine[1], T. Werncke[1], M. Kirstein[1], S. K. Maschke[1], C. Dewald[1], L. S. Becker[1], F. Wacker[1], B. C. Meyer[2], J. B. Hinrichs[1]; [1]*Hanover/DE,* [2]*Berlin/DE (becker.lena@mh-hannover.de)*

Purpose: Current guidance techniques for portal vein puncture rely on the acquisition of an intraprocedural C-arm computed tomography (CACT). This could increase the radiation exposure to the patient. The purpose of this study was to assess the technical success, puncture complications, and procedural characteristics of TIPS placement using image fusion of preprocedural multidetector-computed-tomography (MDCT) and intraprocedural fluoroscopy for portal vein puncture guidance.
Methods and materials: From 11/2018-06/2019, 27 consecutive patients (18 men, 59 years) with elective TIPS placement were included. A 3D vascular map (3D-VM) was generated by drawing polylines in the hepatic and portal veins on MDCT, which was acquired for the evaluation of the TIPS procedure. Afterwards, the 3D-VM was semi-automatically registered to fluoroscopic images in two perpendicular views and served as a real-time overlay during the intervention to guide the portal vein puncture. Technical success, puncture complications, and procedural characteristics such as overall procedural time (OPT), puncture time (PT), and the dose area product (DAP) were recorded and compared to the literature.
Results: TIPS placement by use of 3D/2D-fusion was technical successful with a significant reduction of the PSG (PSGpre-TIPS15±3mmHg, PSGpost-TIPS4±3mmHg; p<0.00001). No major complications occurred. The OPT was 64±29 min and the PT was 14±6 min, which is comparable to the literature. The DAP of 10748±9384uGy*m2 was lower than the reported DAP for CACT-assisted TIPS procedures.
Conclusion: TIPS placement using 3D/2D-fusion is effective, fast, and safe. It has the potential to reduce radiation exposure to the patient by at least 30% compared to published CACT-assisted TIPS procedures.
Limitations: A small, retrospective study without a control cohort. Large cohort studies are required to confirm the benefits for the patients.
Ethics committee approval: The Human Subjects Research Review Board of the Hanover Medical School approved our retrospective study and written informed consent was obtained.

Application of a liver biopsy as a treatment strategy determinant in Budd-Chiari syndrome

F. Rafiee, A. Rasekhi, B. Geramizadeh, H. Laalinia, P. Keshavarz*; Shiraz/IR (faranakrafiee1367@gmail.com)*

Purpose: Budd-Chiari syndrome (BCS) is hepatic venous outflow obstruction. The primary goal of treatment is the resolution of hepatic congestion in order to improve liver perfusion and preserve hepatocytes function. Medical management, recanalisation of stenotic or occluded hepatic veins, portosystemic shunting, and eventually liver transplantation are the treatment options. The aim of this study is to determine if angioplasty intervention can

substitute the portosystemic shunting by means of a new histopathological grading system for zone 3 congestion in BCS.
Methods and materials: In a retrograde study, we reviewed 34 cases of BCS, diagnosed on radiology/pathology basis, who underwent a biopsy of the explanted liver prior to transplantation. Alongside the extent and amount of irreversible fibrosis, we emphasised other pathologic changes including sinusoidal and central venular dilatation. The pathologic slides were rechecked and, according to a new congestion scoring system, patients were categorised considering the extent of central venular and sinusoidal dilatation. Total scores of 3-8 were applied for each patient.
Results: According to radiologic findings, 11 patients were in the proximal type subgroup, all representing a histopathologic score of 4 or less (score 3 in 6 patients, score 4 in the others). The remaining 23 patients were in the distal type category, including 7 patients with score 5 and the rest demonstrating score 6 or more. After pathological/radiological correlation, the study revealed that the more proximal the location of the venous obstruction was, the less sinusoidal and central venular dilatation.
Conclusion: The use of histopathology is beyond determining the presence of fibrosis. Liver biopsy results are useful in predicting the site of venous obstruction in BCS, thus considered as valuable pretreatment findings.
Limitations: The small sample volume.
Ethics committee approval: n/a

RPS 1709-13 09:52
Transjugular intrahepatic portosystemic shunt using the new GORE VIATORR controlled expansion endoprosthesis: a single-centre experience
R. Miraglia[1], L. Maruzzelli[1], G. Sparacia[1], G. Mamone[1], A. Di Piazza[1], M. Milazzo[1], C. Cannataci[2], C. Gozzo[1], A. Luca[1]; [1]*Palermo/IT,* [2]*Msida/MT*
(christinecannataci@gmail.com)

Purpose: To evaluate the mid-term clinical efficacy and complications of transjugular intrahepatic portosystemic shunt (TIPS) creation using the new controlled expansion ePTFE covered stent (VCX) for portal hypertension complications.
Methods and materials: From 7/2016-6/2019, 139 consecutive patients received TIPS using VCX in a single centre.
Results: TIPS indications were refractory ascites (n=89), variceal bleeding (n=41), and other (n=9). The mean MELD score was 12.0 ± 4.6 (6-33). The mean age was 59.1 ± 10.4 (10-78) and the mean follow-up was 12.2 months (± 8.0, range 1-33). In 9 patients (cavernoma n=4, massive thrombosis n=4, and Budd-Chiari n=1), TIPS was directly dilated to 10 mm in diameter. In 122 patients, TIPS was dilated to 8 mm with a final PSG<12 mmHg or a PSG reduction≥40%, compared to the baseline PSG. In 8 patients, not reaching the haemodynamic target, the stent was further dilated to 10 mm in diameter during the same session, reaching the haemodynamic target. Overall clinical success was achieved in 118/139 (85%) patients (80% in refractory ascites, 95% variceal bleeding, and 80% other). Overt hepatic encephalopathy was observed in 21 patients (15%). TIPS revision was performed in 18 patients (13%). 3 patients (2%) underwent stent reduction. 28 patients (20%) died during follow-up of causes not related to TIPS. 17 patients (12%) underwent a liver transplant.
Conclusion: VCX can help to optimise the haemodynamic target during TIPS creation with a good clinical outcome and a reasonably low complication rate.
Limitations: A longer follow-up is necessary to confirm this data.

The worrisome impact of an inter-rater bias on neural network training
O. Shwartzman, H. Gazit, I. Shelef, T. Riklin-Raviv*; Beersheba/IL*
(orshw@post.bgu.ac.il)

Purpose: We quantitatively evaluated the impact of inter-rater bias in manual segmentations of medical images on the output of artificial neural networks (ANNs).
Consistent differences in manual image annotations influence supervised ANNs' training processes. Thus, automatic segmentations of ANNs trained on different sources will be consistently different as well.
Methods and materials: MRIs of MS patients annotated by two radiologists with different levels of expertise were collected. CT scans of intracranial haemorrhage (ICH) patients were annotated twice: manually and semi-manually. We trained an ANN (U-Net) on annotations from one source and tested its output segmentations on annotations from another source, using Dice scores as matching criteria.
We used classifier ANNs to test (using hit-rate) if two sets of automatic segmentations produced by two identical U-Nets that were trained on different source segmentations could be distinguished. We calculated MS-lesion loads and ICH volumes based on the raters' and the U-Nets' segmentations and compared the differences.
Results: Lower Dice scores were obtained between the outputs of ANNs trained on annotations of one rater and tested on another (cross-evaluation experiment). Classification hit-rates were higher for U-Nets that were trained on different sources than for the sources' annotations themselves: ICH 0.92 (manual) versus 0.95 (automatic); MS 0.9 (manual) versus 0.93 (automatic). Differences in volumes calculated based on automatic segmentations of ANNs, trained on different sources, increased and became more consistent.
Conclusion: Segmentation bias between different raters is amplified in ANNs' training as the ANNs generalise the manual segmentation examples to the test data. Therefore, ANNs' segmentation and volume calculation, for the same input images, can be significantly different depending on the training sources.
Limitations: Testing specific segmentation ANN architecture.

Aging AI: how machine learning models go out of sync
O. Pianykh[1], C. Crowley[2]; [1]*Newton Highlands, MA/US,* [2]*Boston/US*
(opiany@gmail.com)

Purpose: To investigate whether the accuracy of machine learning models used in radiology degrades with time.
Methods and materials: Machine learning (ML) gains an increasing role in radiology. Currently, most ML models use the same static "train once, deploy everywhere" approach. However, the environments and data used by these models evolve all the time. As a result, static models run into the risk of becoming outdated.
To verify this hypothesis, we used a full year of operational patient records from Massachusetts General Hospital. We trained several ML models to predict operational events, such as patient wait times or imaging delay times. We varied the age of the training data between 0 (current) and 12 months, and we varied the volume of the training set from 1 to 12 months. The performance of the trained models was then assessed based on the prediction accuracy for one month of test data. The goal was to see whether the size or the age of the training dataset affects the accuracy of the model results.
Results: A random forest model provided the most accurate prediction with R^2=0.65. AI models needed at least 1 month of training data volume to become accurate. However, the age of the training data had a visible effect on the model

accuracy: models trained on data older than 8 months produced significantly less accurate results.
Conclusion: As AI becomes increasingly present in radiology, more attention should be paid to maintaining high AI model accuracy. To stay accurate, AI models must be retrained/reevaluated on a regular basis.
Limitations: ML model quality may depend on the data available at each facility.

Cloud computing in combination with multi-scale deep reinforcement learning for 3D-landmark detection applied on whole-body organ volumetric analyses for the building of organ-specific databases

D. J. Winkel[1], H.-C. Breit[1], A. Ezzi[2], B. Stieltjes[1]; [1]*Basel/CH,* [2]*Princeton/US*

Purpose: To showcase a fully automated workflow combining deep reinforcement learning (DRL) for whole-body volumetric analyses and cloud-based post-processing and storing of data on 10,508 whole-body organ volumes.
Methods and materials: 431 retrospectively acquired multiphasic CT datasets with 10,508 volumes were included in the analysis (10,344 abdominal organ volumes, 164 lung volumes). AI-based whole-body organ volumes were determined using a multi-scale DRL for 3D body markers detection and 3D structure segmentation. The algorithm was trained for whole-body organ volumetry on 5,000 datasets. The data was uploaded to a cloud-based application with integrated DRL software, allowing to group data by diseases. Total processing time for all volumes and mean calculation time per case was recorded. Repeated measures analysis of variance (ANOVA) were conducted to test for robustness, considering the contrast phase and slice thickness. Final whole-body organ metrics were automatically outputted in comma-separated values format.
Results: The algorithm calculated organ volumes for the liver, spleen, and right and left kidney (mean volumes in mL: 1868.6, 350.19, 186.30, and 181.91, respectively), and for the right and left lung (2363.1 and 1950.9). We found no significant effects of the variable contrast phase or the variable slice thickness on the organ volumes. The mean computational time per case was 10 seconds. The total computational time for all volumes was 1 hour and 11 minutes.
Conclusion: We were able to show that DRL in combination with cloud computing enables a fast processing of substantial amounts of data, allowing to build up organ-specific databases.
Limitations: n/a

Adversarial attacks in the detection of pneumothoraces from chest radiographs: addressing a vulnerability of deep neural network classifications in the clinical setting

A. M. Bucher[1], A. Distergoft[2], D. Kügler[3], A. Rajkarnikar[2], M. Uecker[2], T. J. Vogl[1], D. A. Mukhopadhyay[2]; [1]*Frankfurt am Main,* [2]*Darmstadt/DE,* [3]*Bonn/DE*

Purpose: Adversarial attacks are malicious changes to the input images that are below the detection level of a human reader, yet can completely falsify the classification of a deep neural network (DNN). We tested the vulnerability of a state-of-the-art DNN classifier in the detection of pneumothoraces by several adversarial attack variations.
Methods and materials: A state-of-the-art DNN architecture (ResNet) was trained on 9,265 chest radiographs and the locations of pneumothoraces were manually annotated. We tested a total of 600 modified images (I_A) based on 150 comparable chest x-ray images (I_C). Attack categories were basic iterative method (BIM), fast sign gradient method (FGSM), deep fool attack (DF), and saliency map attack (SAM). Annotation by a trained radiologist reader was performed for each test image.
Results: The accuracy of classification by the human reader was comparable between groups (I_C: 98.6%, I_A: 99.3%, p=0.325). DNN classification for I_C was an accuracy of 83.3%, FPR: 0.1, FNR: 0.35. Classification was significantly falsified for I_A with an accuracy of 16.7%, FPR: 0.9, FNR: 0.65; p<0.001. True-positive rates were 0.65 (I_C) and 0.35 (I_A), and true-negative rates were 0.9 (I_C) and 0.1 (I_A; p<0.001). AUC was 0.78 (I_C) and 0.23 (I_A, p<0.001). Attack strength measured by accuracy, FNR, FPR, and AUC were comparable across attack categories (p>0.1 each).
Conclusion: A wide range of adversarial attacks were highly effective to falsify DNN-based detection of pneumothorax from chest x-rays. This vulnerability needs to be carefully addressed when transferring DNN classifiers into the clinical setting.
Limitations: Effectiveness should be validated in a larger dataset.

An intelligent way to choose a training dataset for annotation to improve the segmentation accuracy of a deep segmentation network model

H. Haque[1], M. Hashimoto[2], N. Uetake[1], N. Toda[3], M. Jinzaki[2]; [1]*Hino/JP,* [2]*Tokyo/JP,* [3]*Shinjuku/JP (hasnine.haque@ge.com)*

Purpose: The annotating process is tedious and time-consuming. Effectively selecting a minimum number of representative unannotated training datasets out of a large-scale heterogeneous dataset is challenging. Our purpose was to identify training datasets iteratively and retrain current model to segment thigh muscle and produce state-of the-art segmentation performance.
Methods and materials: IRB-approved 3,000 clinical CT images were used for this study. A 3D-UNet base model, which was previously trained to segment thigh volume into 11 muscle classes by a small cohort of reference datasets, was used. An iterative active learning framework was developed which identified the datasets out of all datasets where base model segmentation prediction had a higher uncertainty in prediction and could produce a positive effect on segmentation accuracy if used for re-training. Identified datasets were further clustered by their similarity features and 10 representative datasets were selected for annotation in each iteration. All re-trained models performance was evaluated by randomly selected 18 test thigh volume datasets. We compared the average surface distance (ASD) as a segmentation performance metric when the base model was re-trained by the same number of randomly chosen datasets.
Results: After the second iteration, the evaluation indicates a 53% improvement in median ASD over all muscle class as compared to a 22% increase when re-trained with randomly chosen datasets. Paired t-test with a statistical significance score ($p < 0.005$) shows clear improvement of the segmentation performance.
Conclusion: Retraining a base model with the identified datasets by the active learning framework achieved higher segmentation accuracy in comparison to when trained with a randomly selected dataset. To keep the segmentation performance at the expected range for growing datasets, the framework finds the effective training datasets for annotation and reduces unnecessary annotation workload.
Limitations: The current model does not support images with a metal artefact.

Can AI pick up significant abnormalities missed on the original read, hence contributing to QA?: a deeper dive into the abnormalities detected by AI versus the original radiologist

A. K. Sahu, B. Aggarwal; *New Delhi/IN (drsahuamit@gmail.com)*

Purpose: To evaluate the accuracy of deep learning in detecting clinically relevant abnormalities in chest x-rays in outpatient tertiary care centres and comparing it with the radiologist's read.
Methods and materials: 5,000 random chest x-rays from outpatient departments of 5 tertiary care centres were sent to deep learning as anonymised data for analysis. Abnormalities specified were nodule, calcification, cavity, consolidation, and blunting CP angle. After analysing, a deep learning algorithm provided 400 x-rays, mentioning specified abnormalities. Selected x-rays were

blindly read by 3 radiologists who gave their interpretation on specific abnormalities. A comparison was made between the primary read, AI read, and the interpretation of the 3 radiologists to pick up clinically relevant findings which were missed in primary read.
Results: Comparing the original reports of 403 cases, 3 radiologist majority opinion agreed with the AI for 75 ruled as normal and 188 as a missed finding in the original report. Individual radiologist concordance with AI with Cohen's Kappa values were 0.648, 0.789, and 0.457. Out of the discordant set, AI reads on cardiomegaly, opacity, and blunting of CP angle were positive for 79.75 and 41 cases. The highest concordance between the AI read and reporting radiologist was for cardiomegaly: 47 cases where all three radiologists agreed. The most common discordance was cardiomegaly, with reviewing radiologist agreement of 27%. The most significant missed finding by the AI read was cardiomegaly, with a total of 72 and blunting of CP angle of 6 cases; parenchymal opacities in 19 cases.
Conclusion: A deep learning algorithm can detect clinically relevant abnormalities in chest x-rays, which can be missed by radiologists, as small nodules, lung parenchymal/pleural calcification, and blunted CP angles, thus increasing diagnostic accuracy.

RECOMIA: a cloud-based platform for artificial intelligence research in radiology

P. Borrelli[1], O. Enqvist[1], J. Ulén[1], R. Kaboteh[1], E. Trägårdh[2], L. Edenbrandt[1]; *[1]Gothenburg/SE, [2]Malmö/SE (pablo.borrelli@vgregion.se)*

Purpose: The Research Consortium for Medical Image Analysis (RECOMIA) is a not-for-profit organisation with the objective of promoting research in the fields of artificial intelligence (AI) and medical imaging. RECOMIA aims at minimising the time and effort researchers need to spend on technical aspects such as display and transfer of DICOM images, legal aspects such as de-identification, GDPR, and HIPAA compliance, and quality aspects such as display tools so that medical experts can review and correct AI-segmentations in a cloud-based DICOM-viewer.
Methods and materials: Radiologists and nuclear medicine specialists have used the RECOMIA platform to manually annotate up to 100 organs in more than 300 CT studies. Not all organs were annotated in all images; in total, more than 10,000 were annotated. The manual annotations were used to train convolutional neural networks (CNN) to perform automated organ segmentation in CT images. The CT scans were split into training (80%) and validation (20%) groups.
Results: The CNN-based segmentations were compared to the manual segmentations of the validation group. There was agreement on 93.7% of the manually-labelled pixels. Conversely, there was agreement on 94.7% of the automatically-labelled pixels. The pixels considered background both manually and by the CNN are not included in these numbers. The run-time of the CNNs was about 2 minutes on a desktop computer.
Conclusion: AI-based tools can provide highly accurate and reproducible organ segmentation, similar to those obtained manually by radiologists, but much faster. We continue to train new CNNs to continuously improve performance. The tools developed in this project are available by request at www.recomia.org for research purposes.
Limitations: The tools are not for clinical use and not available for commercial purposes.

Integrating machine learning pipelines into clinical workflows with DICOM message queues

V. Saase, A. Junge, H. Wenz, C. Groden, M. E. Maros*; Mannheim/DE (vsaase@gmail.com)*

Purpose: We present a prototype that implements a modular, distributed, and parallel analysis pipeline in MRI reporting workflows of neuroradiology. The modular software architecture allows us to quickly exchange parts of the pipeline for experiments and testing while ensuring the stability and performance of the remaining system. We integrate image viewing, structured reporting, and monitoring by using custom user interfaces and well-established open-source software.
Methods and materials: Our implementation comprises multiple submodules: a web-based structured reporting editor, a machine learning-based MRI perfusion pipeline, a traditional rule-based processing pipeline, a viewer application, a PACS connection, and a high-performance database. We use DICOM metadata as messages for the standardised communication between modules. Modules are implemented in various programming languages, thus enabling us to choose the best tools for the specific requirements and lowering the entry barrier for less experienced developers. Modules can be distributed across the network, making use of dedicated hardware, thereby reducing the need for moving bulk data across slow connections.
Results: A pilot trial with 10 stroke reports and 10 tumour reports (Nreader=3) showed that reporting was significantly faster ($p<0.05$), more structured ($p<0.05$), and contained more repeatable quantitative measurements ($p<0.05$) when compared to our legacy system.
Conclusion: Flexible, standardised, and open source software is the way forward in the quest to integrate machine learning workflows into clinical practice, improving quality and performance.
Limitations: This study is a proof of concept of a tool bridging clinical work and research. The development of specific modules will be needed when transferring it to other sites. We are prohibited from distributing our software for clinical use by European law.
Ethics committee approval: The project was approved by the local ethics committee (2017-825R-MA, 2017-828R-MA).
Funding: No funding was received for this work.

The methodology of the formation of databases for machine learning

A. Meldo, T. Trophimova, O. Tsyganskaya, K. Malinovskaya, I. Prokhorov*; St. Petersburg/RU (anna.meldo@yandex.ru)*

Purpose: To create a general methodology of the generation of databases for machine learning algorithms
Methods and materials: 450 anonymised chest CTs were included in the dataset. The RadiAnt DICOM Viewer has been chosen for modifying and dealing with the dataset. The prepared dataset was archived on the server of the oncological centre before the morphological diagnostics. Then the data was anonymised with the DicomCleaner™, renaming them with a special code. We used nodule's shape, internal, and external structure as a feature and represented them into histograms for radiomix. After the morphologic confirmation, we assigned some class label to each case.
Results: We created the database LIRA (Lung Image Resource Annotated) for the development and testing of CAD. All cases were confirmed morphologically. In our study, 65% of LCs had a typical CT, 26% of CT images corresponded to different diseases which require an additional differential diagnostic criteria, and 9% of LC cases were extremely difficult to recognise by means of CT due to an atypical visualisation image. Class labels for subsets were "typical LC", "atypical", and "not cancer".
Conclusion: One of the conditions for successfully using the medical CAD systems is a correctly created database which corresponds with clinical and radiological interpretation. We would like to point out that the main proposed idea of the methodology of creating the medical databases can be formulated as follows: structurisation of the data, their homogenisation and verification of diseases, and the inclusion of the "atypical" cases and cases which look similar to studying disease. The dataset LIRA contains class labels for each nodule to develop the differential diagnostic intellectual algorithm.
Limitations: n/a

RPS 1705-10 09:24
Super AI and supermodalities: the future of radiology?
D. Gicovate; *Jerusalem/IL (dgicovate@yahoo.com)*

Purpose: To research possible future directions for AI technology in radiology. We analyse the suitability of a hypothetical "super AI" technology capable of integrating multiple studies simultaneously. Additionally, we compare super AI with the possibility of developing a multi-modality-scanner ("supermodality").
Methods and materials: Super AI: combining AI packages will be possible to get better disease diagnosis.
We analysed some factors to develop such technology:
A) The time factor between different studies.
B) The patient position.
C) Modality technology.
D) The radiologist as an integrator of knowledge.
E) The contrast agent.
Supermodality: multimodality machines developed are the PET-MRI. PET-CT, CT-ultrasound-registration, etc, are common hospital practices.
What about a single machine that can scan using different technologies? Will it reduce the time to diagnose?
Results: Those new machines will suppose a completely new paradigm and new radiologist knowledge, and new contrast agents, may be needed.
Conclusion: Different AI packages can discover different findings in different kinds of studies. Combining modalities or combining AI packages will substantially improve diagnosis.
Two different strategies can be adapted to produce a more complete diagnosis in a multi-exam scenario:
1) To develop a super AI system, as a software solution, capable of analysing and integrating the data of different AI packages
2) To develop a new generation of machines: a super modality that scans the patient using several technologies at the same time (CT + MRI + ultrasound + etc.) and reducing patient positioning, time differences, contrast agents factors, and others.
Limitations: Both kinds of technologies do not exist today. Even if the software solution (super AI) is the easy one, and probably the most possible to develop in the next few years, a mix of the two strategies will be the only way to reach the next level of radiology.
Ethics committee approval: n/a
Funding: No funding was received for this work.

The impact of radiomic feature selection on clinical modelling
J. van Lunenburg, W. H. K. Chiu; *Hong Kong/HK (jurgen@hku.hk)*

Purpose: Software choice often dictates what radiomic features can be extracted from images. This study analyses how different feature sets affect clinical models in two cancer cohorts: PET oesophagus (in-house dataset) and CT lung (open dataset).
Methods and materials: 95 patients (65 training and 30 validation cohorts) who had undergone pre-treatment 18F-FDG-PET studies were included and classified as those who achieved complete pathological response (pCR) and those who did not. The primary tumours were segmented using a fixed threshold approach, radiomic features were extracted, features were annotated according to the international biomarker standardisation initiative. Feature reduction with the minimum redundancy maximum relevance method was performed. Logistical regression and random forest models for clinical outcomes were constructed and compared using ROC curves, decision curves, and McNemar's test.
Results: Of the 5 feature sets tested, AUC values for the two models ranged between 0.6 and 0.87. Reduced feature sets did not have much overlap (10-25%) and showed substantial differences in their ability to predict outcomes with our models and datasets. A combined superset showed the best performance (AUC 0.87) but did not show much reduction in feature correlation.
Conclusion: High-dimensional data requires extensive feature reduction and increased scrutiny for overfitting, but if a proper methodology is applied, the results of combining multiple feature sets may be beneficial for modelling with radiomics in cancer.
Limitations: The PET dataset is not very large (low incidence and expensive modality) and the event frequency is slightly below 40%. The fixed threshold segmentation may be less accurate for lesion size, but it was chosen to maximise radiomics stability.
Ethics committee approval: The study was approved by the local ethics committee in accordance with the Helsinki Declaration and all patient information was anonymised prior to analysis.
Funding: No funding was received for this work.

Practical implementation of artificial intelligence solutions in a multi-country healthcare organisation
R. Illing[1], A. Juhos[1], T. Sparkes[2], I. Fulop[1], R. Fenyi[1], O. Dumitroiu[3], K. Katsari[2]; *[1]Budapest/HU, [2]Amsterdam/NL, [3]Bucharest/RO (katia.katsari@affidea.com)*

Purpose: The value proposition of artificial intelligence (AI) solutions in healthcare have been well described and it is apparent that 'narrow AI' will have a role in every stage of the clinical workflow. The deployment of AI solutions in the clinical workflow of a multi-country healthcare organisation has many challenges, but establishing a systematic and unified framework can lead to successful outcomes. By defining measurable performance indicators, it is possible to track in real-time whether actions give benefits to all stakeholders; patients, referrers, and business partners.
Methods and materials: In order to establish the framework of AI deployment in the clinical workflow, working groups were formed at a group and country level between clinical, legal, data protection, digital, operational, commercial, and marketing to identify all areas of relevance in a project management approach.
Results: A unified framework of AI deployment was identified in eight steps:
- The selection criteria for AI solutions, pilot centres, and countries.
- A legal review including medical device class, intended use, and data protection impact assessment.
- A technical architecture review including digital infrastructure requirements and the integration of an AI solution.
- The definition of workflows for the assessment of AI solution benefits.
- The training of healthcare professionals.
- The definition of key performance indicators.
- The commercialisation process.
- The preparation of stakeholders' information and communication strategy and material.

Conclusion: The framework designed is robust enough to encompass the introduction of different AI solutions across the network. However, minor methodological adjustments are required for each specific AI solution to meet the requirements of use and implementation.

The role of a deep learning-based artificial intelligence diagnostic system in assisting the establishment of the gold standard in clinical validation studies
P. Borrego[1], E. Ladera González[1], P. Sousa[1], M. T. D. Maristany Daunert[1], D. Wang[2], Y. Shen[2], S. Drago[1], Y. Sun[3], J. Munuera[1]; *[1]Barcelona/ES, [2]Beijing/CN, [3]Wiesbaden/DE (pepmunuera@hotmail.com)*

Purpose: The gold standard is critical for clinical validation studies but usually time-consuming for researchers. This project aimed to explore whether a deep learning (DL)-based artificial intelligence (AI) diagnostic system would benefit the researchers in establishing the gold standard by reducing the discrepancies between them.
Methods and materials: In this study, we utilised 196 CXR scans which were diagnosed as either pneumonia or effusion and employed the DL AI system (InferRead DR Chest Research, Infervision) to study its effects in eliminating the discrepancies when generating the gold standard. Two senior radiologists participated in the reader study. They reviewed the CXR images with and without the aid of an AI diagnostic system at an interval of 4 weeks. Discrepancies of their reviewing results were analysed and evaluated by Cohen's Kappa index.
Results: There were 18 cases that were diagnosed differently by the two senior radiologists when they reviewed the CXR images alone. With the assistance of the AI diagnostic system, the number of differentially diagnosed cases dropped to 7 cases, leading to a 61.1% reduction in discrepancies. Of note, the Kappa scores increased from 0.806 to 0.928 after utilising the AI diagnostic system. In particular, according to the ground truth of these CXR images, utilisation of the AI diagnostic system eliminated 17 discrepancy cases in which 8 false-positive cases and 7 false-negative cases were corrected. Meanwhile, among the 6 new introduced discrepancy cases, one was a false-positive case that was corrected by one radiologist with the help of the AI system.

Conclusion: A DL-based AI diagnostic system greatly reduced the diagnostic discrepancies among radiologists and could be utilised to assist the establishment of a gold standard in clinical validation studies.

The utility of artificial intelligence/machine learning for the detailed evaluation of contrast media comparison studies
J. W. Patriarche[1], D. Patriarche[2], A. Kuhn[3], M. J. Kuhn[4]; *[1]Bellevue/US, [2]Ottowa/CA, [3]Milwaukee/US, [4]Peoria, IL/US (mkuhn6@gmail.com)*

Purpose: Contrast media comparison studies with artificial intelligence/machine learning (ML) software provides opportunities to look at enhancement characteristics quantitatively, providing greater clarity, reliability, and reproducibility.
Methods and materials: Using the change detector software produced by A.I. Analysis, Inc. (Seattle, WA), 24 patients with biopsy-proven glioblastoma multiforme were evaluated. Each patient had received equal doses of gadoteridol and gadobutrol within a 2-10 day time period. The software performs a novel ML enhancement calculation that automatically rates the degree of enhancement from 0.0 to 1.0 per voxel and the change in enhancement from -1.0 to +1.0. ROIs were manually defined for regions that were non-enhancing and unchanging, as well as enhancing and changing. Mean calculated enhancement values of actually non-enhancing regions were compared between subtraction and the ML technique. Mean calculated contrast to background ratio (CBR) values of actually enhancing/changing regions were compared between the subtraction and ML technique.
Results: For the actually unchanging/non-enhancing regions, the median ratio of mean calculated enhancement for subtraction technique versus AI technique was 13.34. The p-value using the ratio paired t-test was $<10^{-12}$. For the actually changing/enhancing regions, the average ratio of CBR between the ML technique and the subtraction technique was 7.6. The p-value using the ratio paired t-test was $<10^{-12}$.
Conclusion: The ML technique permits an automatic and reproducible calculation of enhancement, as well as a change in enhancement between MR studies. The ML technique provides enhancement and change in enhancement maps that are dramatically darker in the non-enhancing regions, and provide a much greater contrast for the actually enhancing/actually changing regions.

Deep learning for natural language processing (NLP) in radiology
V. Sorin, Y. Barash, E. Konen, E. Klang*; Ramat Gan/IL (verasrn@gmail.com)*

Purpose: Natural language processing (NLP) enables the conversion of free text into structured data. Recent innovations in deep learning technology provide improved NLP performance. We aimed to survey deep learning NLP fundamentals and review radiology related research.
Methods and materials: This systematic review followed the PRISMA guidelines. We searched for deep learning NLP radiology studies published up-to September 2019. MEDLINE, Scopus, and Google Scholar were used as search databases.
Results: 10 relevant studies published between 2017 and 2019 were identified. Deep learning models applied for NLP in radiology are convolutional neural networks (CNN), recurrent neural networks (RNN), long short-term memory (LSTM), and attention networks. Deep learning NLP applications in radiology includes flagging of diagnoses such as PE and fractures, labelling follow-up recommendations, and automatic selection of imaging protocols. Deep learning NLP models perform equally or better than traditional NLP models.
Conclusion: Research and the use of deep learning NLP in radiology is increasing. An acquaintance with this technology can help prepare radiologists for the coming changes in their field.
Limitations: This systematic review has several limitations. First, heterogeneity of studies and variability in measures between studies prevented a meta-analysis. Second, we limited our search to radiology applications. Deep learning NLP is implemented for the analysis of many kinds of medical texts, not just limited to our field. Finally, deep learning for NLP is a rapidly expanding topic. Thus, there may be concepts and applications published after our review was performed.

3T blood-oxygen-level dependent (BOLD) MRI in renal transplants for the differentiation between acute rejection (AR) and acute tubular necrosis (ATN)
A. Ramadan, M. Shaaban, M. H. K. Khalifa, M. Zeid, N. Baddour, O. Ezz*; Alexandria/EG (doctoradelramadan@gmail.com)*

Purpose: To assess the diagnostic accuracy of 3T BOLD-MRI for the differentiation of AR and ATN in the transplanted kidney.
Methods and materials: This study included 75 renal graft recipients from living donors in 22 months. They were divided into group A, including 32 recipients with stable graft function, group B, and group C, including 25 and 18 recipients with pathologically proven AR and ATN, respectively. Each recipient was subjected to 3T BOLD-MRI using a breath-hold multiple fast-field echo sequence to obtain R2* maps in coronal planes. Qualitative analysis at colour-coded R2* maps and quantitative analysis by placing ROIs on R2* maps, measuring mean ±SD of C-R2* and M-R2*, and calculating MCR were performed. The ANOVA test was applied for comparison between different groups. ROC curve analysis determined the recommended cutoff values with corresponding sensitivity, specificity, PPV, NPV, and accuracy.
Results: The study included 75 adult recipients; 32 as control and 43 with graft dysfunction. Pathology was 25 AR (group B) and 18 ATN (group C). Qualitative analysis showed a visual difference between different groups. Quantitative analysis revealed significantly higher C-and M-R2* values in the ATN group (21.20±2.54/s and 31.01±3.99/s) than in group A (14.96±1.61/s and 26.38±3.12/s) and the AR group (14.83±2.86/s and 22.28±5.29/s), respectively. For the prediction of ATN versus AR, the recommended cutoff value was >18.93/s and >26.35/s for C-R2* and M-R2*, respectively, with high sensitivity and specificity, and 90.7% accuracy. MCR was lower in the AR and ATN groups than in the control group, but no difference was found between the AR and ATN groups.
Conclusion: 3T BOLD-MRI is promising for the evaluation of renal grafts with the potential ability to differentiate between AR and ATN cases.

Renal allograft dysfunction evaluation using BOLD-MRI

M. E. Abou El-Ghar, H. M. Farg, B. Ali-El-Dein, A. Refaie, T. El-Diasty; *Mansoura/EG (maboelghar@yahoo.com)*

Purpose: To evaluate the role of BOLD-MRI using 3T magnet in the discrimination of renal allograft acute rejection from ATN in the early post-transplant period.
Methods and materials: This prospective study included 78 live-donor renal allograft recipients; 28 with normal function (group 1), 15 with AR (group 2), and 35 with ATN (group 3). Cortical R2* (CR2*), medullary R2* (MR2*), and medullary over cortical R2* ratio (MCR) were measured.
Results: The mean medullary R2* value (24.3 ± 2.5/sec) was significantly greater than the cortical R2* value (18.2 ± 2.2/sec) in normally functioning allografts ($p < 0.001$). The mean MR2* level was significantly lower in the acute rejection (AR) group (20.5 ± 2.5/sec) compared to the normal group (24.3 ± 2.5/sec, $P<0.001$) and ATN group (27.1 ± 1.9/sec, $P < 0.001$). There was also a significant difference in MR2* levels between the ATN group and the normal group ($p < 0.001$). The MCR was higher in the ATN group (1.44 ± 0.22) compared to the AR group (1.17 ± 0.14) and normal functioning group (1.35 ± 0.22), with a significant difference between the 3 groups ($p= 0.001$). The mean CR2* was higher in the ATN group (19.2 ± 2.5/sec) compared to the normal group (18.2 ± 2.2/sec) and AR group (17.5 ± 1.8/sec).
Conclusion: BOLD-MRI is a valuable non-invasive diagnostic technique that can differentiate between AR and ATN in kidney transplants by measuring the changes in intra-renal tissue oxygenation.
Limitations: We included only cases in the early transplant period.
Ethics committee approval: The study protocol was approved by our local institutional transplant committee. Informed consent was obtained from patients.
Funding: No funding was received for this work.

Medullary oxygenation: an important index for evaluating renal function in chronic kidney disease

P. Xin Long, T. Xin Kui; *Beijing/CN (mrpxl@126.com)*

Purpose: BOLD-MRI can provide regional measurements of oxygen content using deoxyhaemoglobin paramagnetic characteristics. Chronic kidney disease (CKD) can affect oxygenation levels in renal parenchyma, which influences the clinical course of the disease. Furosemide may make Na+ -K+ -ATP pump work reduction and oxygen consumption decrease. The goal of this study was to assess renal oxygenation levels in CKD using BOLD-MRI when injecting furosemide.
Methods and materials: 18 healthy subjects and 39 patients with CKD underwent a renal scan using a multi-gradient-recalled-echo (mGRE) sequence with 16 echoes, and 28 of 39 patients underwent the same sequence 7 minutes after injecting furosemide. R2* values of three regions of interest (ROI) of the renal cortex and medulla were measured and their average values were calculated. The difference of R2* was compared between the healthy subjects and all patients. According to eGFR, 28 patients with injected furosemide were divided into a normal eGFR group (group 1,≥90 mL/min/1.73 m^2) and an abnormal eGFR group (group 2,<90 mL/min/1.73 m^2), and the changes of R2* in the two groups after injection were compared. 28 of the 39 patients were confirmed by ultrasound-guided puncture and the other 11 patients had a similar diagnosis based on clinical symptoms and investigations.
Results: Medullary R2*(MR2*) were significantly lower in patients (78 kidneys, MR2*=28.81±4.65 s^{-1}) than in controls (36 kidneys, MR2*=31.18±1.87s^{-1}), $P<0.05$. Medullary to cortical R2* ratios of patients (1.78±0.26) was significantly decreased compared to controls (1.94±1.14), $P<0.01$. After injecting furosemide, R2* variance of the medulla (ΔMR2*＝MR2*pre－MR2*post) in group 1 (6.63±0.66) was higher than that of group 2 (4.03±0.64), $p＜0.01$.
Conclusion: Medullary R2* values in BOLD-MRI when injecting furosemide were an effective index for evaluating renal oxygenation in CKD.
Limitations: No differentiating specific pathogenesis of CKD.
Ethics committee approval: Informed consent was obtained from all participants.
Funding: No funding was received for this work.

Veno-arterial index (VAI): a promising tool for renal transplant rejection

F. Lubinus[1], E. Zuñiga[1], S. Vera[1], E. Villarreal[1], M. Ochoa[1], J. C. Mantilla[2]; *[1]Bucaramanga/CO, [2]Floridablanca/CO (flubinus@hotmail.com)*

Purpose: In transplant rejection, there is an increase in venous flow velocities and a decrease in arterial flow velocities, probably due to graft hardening.
Methods and materials: A diagnostic study was carried out between January 2014 and May 2018. Renal transplanted patients who underwent percutaneous renal biopsy were studied. The veno-arterial index (VAI) was obtained by measuring the flow velocity in the segmental vein at the level of the renal medulla (VFV) and dividing this value by the velocity of the systolic peak of the segmental artery (PSV) in this same location.
Results: 78 records of patients who underwent renal biopsy were analysed. 32 patients (41.5%) suffered from transplant rejection, with 29 presenting with acute rejection. Prior to the study, a normal baseline value of the VAI was obtained by measuring the VAI in 70 individuals without known urological pathology, obtaining a VAI with a median value of 0.30 (range 0.18-0.44). In transplant rejection, the median VAI was 0.67. In kidneys with a negative biopsy for rejection, the median VAI was 0.41 ($p=0.007$), higher than that obtained for the general population which was 0.30 ($p=0.0001$). In subacute and acute rejection, the index was higher (VAI: 0.725). For the severity of rejection, the difference was also statistically significant ($p = 0.0001$).
Conclusion: The results of this study show that the veno-arterial index (VAI) is a useful parameter which could predict transplant rejection when elevated.
Limitations: Studies with a larger number of patients are required to confirm this hypothesis and to obtain a more accurate value of the VAI.
Ethics committee approval: Approved by the ethics committee.
Funding: No funding was received for this work.

Quantitative analysis of wash-out parameters on an MRI DCE T1 weighted-sequence in adrenal lesions with a heterogeneous signal drop on chemical shift imaging

R. Galatola, A. Stanzione, F. Verde, V. Romeo, R. Liuzzi, P. P. Mainenti, E. Guadagno, A. Brunetti, S. Maurea; *Naples/IT (galatolaroberta@gmail.com)*

Purpose: To assess the significance of a qualitative heterogeneous pattern of signal drop on chemical shift (CS) magnetic resonance imaging (MRI) of adrenal lesions (AL) employing quantitative parameters obtained from CS and dynamic contrast-enhanced (DCE) sequences.
Methods and materials: This retrospective study included 3T MRI examinations with AL, for which histopathology, functional imaging, or follow-up data were available as a reference standard. Two radiologists qualitatively grouped AL on CS sequences, showing homogeneous (group A), heterogeneous (group B), and no (group C) signal drop. They manually drew 2D ROIs on CS and DCE images to obtain three quantitative parameters: adrenal signal intensity index (ASII), absolute (AWO), and relative washout (RWO). ANOVA analysis and a post-hoc Dunn's test were used to compare these values among the three groups.
Results: 66 AL were included, divided into groups A (n=19), B (n=23), and C (n=24). ASII values resulted as significantly different among the three groups ($p<0.001$) with the following median values: 71%, 53%, and 0.03%, respectively. AWO and RWO values were not significantly different between groups A and B, showing percentages (AWO: 54% and 46% and RWO: 33% and 29%, respectively) suggestive of a benign nature. Indeed, 98% of lesions were benign, mostly (86%) represented by adenomas. Conversely, AWO and RWO values of group C resulted as significantly different ($p<0.001$) and lower (20% and 9%, respectively) than other groups. Indeed, 58% of these lesions were non-adenomas and the remaining percentage were lipid-poor adenomas.
Conclusion: According to our results, AL showing a qualitative heterogeneous pattern of signal drop on CS images are mainly benign and represented by adenomas, showing dynamic quantitative parameters similar to those with a homogeneous signal drop on CS sequence.
Limitations: A retrospective design and small population.
Ethics committee approval: IRB approved, consent waived.
Funding: No funding was received for this work.

Role of diffusion-weighted imaging in the characterisation of renal masses
A. Sever, M. Yalçın, A. A. Demir, Y. Savas*; Istanbul/TR*
(mdalpersever@gmail.com)

Purpose: To investigate the role of diffusion-weighted imaging in the characterisation of renal masses.
Methods and materials: Between January 2014 and December 2018, patients who had a histopathologically-proven renal tumour were reviewed retrospectively. Patients who had preoperative MRIs were included for the study. Diffusion-weighted images were taken and ADC maps were calculated automatically by the MRI unit. The average ADC values of masses were measured. SPSS was used to evaluate the statistical data.
Results: Of the 142 patients, 108 had malignant masses and 34 had benign masses. Of the malignant patients, 59 had clear-cell RCC, 19 had papillary RCC, 14 had chromophobe RCC, 9 had TCC, and 7 had other rare subtypes. Of the benign patients, 6 had oncocytoma, 3 had angiomyolipoma, and 14 had papillary adenomas, metanephric adenomas, and infectious pseudotumours. 11 had benign cystic lesions of the kidneys.
The difference between ADC values of malignant and benign masses wasn't statistically significant (0.92 vs 0.88 × 10^{-3} mm^2/s; p>0.05). Clear-cell RCCs had higher ADC values than non-clear-cell RCCs (1.09 vs 0.73 × 10^{-3} mm^2/s; p<0.05). RCCs had higher ADC values than non-RCCs (0.96 vs 0.69 × 10^{-3} mm^2/s; p<0.05). Oncocytomas had higher ADC values than chromofobe RCCs (1.27 vs 0.73 × 10^{-3} mm^2/s; p<0.05). The difference between low-grade RCCs (Fuhrman grade 1-2) and high-grade RCCs (Fuhrman grade 3-4) was statistically significant. Low-grade RCCs had higher ADC values (1.06 vs 0.9 × 10^{-3} mm^2/s; p<0.05).
Conclusion: ADC measurements may help in the differentiation of certain renal masses. It should be encouraged to be used in appropriate situations.
Limitations: The retrospective nature of the study.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

RPS 1707-7 09:06
The change of total kidney volume after renal transplant in patients with autosomal polycystic renal disease: does it play a role in the indications and optimal timing decision for native kidney resection?
L. Marcolin, L. M. Cacioppa, M. Ruggeri, G. Scalas, N. Sciascia, I. Capelli, R. Golfieri, G. La Manna*; [1]Bologna/IT*
(laura.cacioppa@gmail.com)

Purpose: Autosomal dominant polycystic kidney disease (ADPKD) is characterised by a progressive enlargement of kidney cysts, often leading to end-stage disease with the need for renal transplantation (RT) and native kidney nephrectomy (NN). Few studies have investigated the appropriate timing for NN and the role of the change in total kidney volume (TKV) after RT in NN indications.
Methods and materials: From January 2008 to December 2018, all polycystic patients who underwent RT in our centre were recorded and retrospectively reviewed. TKVs were evaluated with volumetric analyses on computed tomography (CT) scans performed before and one year after RT in patients who underwent RT alone, and in those scheduled for RT who also required NN. Mean TKV values were height/age, adjusted according to imaging classification of ADPKD (hTKV) and compared.
Results: A total of 182 RTs were collected; 50 patients (27.5%) underwent NN (29 bilateral and 21 unilateral). NN procedures were pre-RT, post-RT, and simultaneous to RT in 54 (76%), 11 (15.5%), and 6 (8.5%), respectively; 34 (47.9%) due to symptoms occurrence and 37 (52.1%) to allow graft positioning. The median age was 54,6 ± 8,7. The mean hTKVs showed a non significant post-RT reduction in the group submitted to RT alone (1866.1±1005.2 vs 1863.2±1075.4 ml/m;p=ns). Compared to those submitted to RT alone, patients who underwent NN showed a higher mean pre-RT hTKV (2301.7±1100.7 vs 1651±994.3 ml/m;p=0.1).
Conclusion: Despite the natural course of native polycystic kidneys, after RT is not well known and indications and timing of NN in patients scheduled for RT are controversial. Our study showed how TKV could be a measurable tool to determine critical kidney volumes at risk of complication and requiring future NN. Decisions for or against NN should take into account TKV reduction after RT and the presence of symptoms, complications, or unavailable graft space in order to avoid additive risks.

VI-RADS: do we really need all multiparametric data?
J. Gmeiner, N. Garstka, S. Sevcenco, P. A. T. Baltzer*; Vienna/AT*
(jasmingmeiner@yahoo.de)

Purpose: To investigate the diagnostic performance of the overall VI-RADS score and its individual parameters in assessing muscle invasivness and grade of bladder cancer (BCa).
Methods and materials: In this IRB-approved, prospective single-centre cross-sectional observational study, patients with BCa underwent preoperative multiparametric MRI at 3T including T2w, DWI, and DCE images. Evaluation according to the VI-RADS scoring system was performed by two radiologists independently, blinded to histological findings. The performance of mpMRI and VI-RADS for determining muscle invasiveness and grade of BCa was compared by using ROC analysis.
Results: The median age of 45 included patients was 67.6, range 28-90 years. Among 45 BCa, 13 (29%) were identified as muscle-invasive and 32 (71%) as non-invasive BCa. The AUC for VI-RADS to predict muscle invasion was 0.975 (95% CI: 0.877 to 0.999) and 0.866 for VI-RADS to distinguish high-grade from low-grade BCa (95% CI 0.728 to 0.951). There was no significant difference between the AUC of single parameters (DCE, T2w and DWI) compared to the total VI-RADS score (p=1.000, p=0.408, p=0.264 for muscle invasion; p=1.000, p=0.2644, p=0.828 for grading).
Conclusion: Our results indicate that VI-RADS is an effective clinical decision rule to diagnose BCa grading and invasiveness. The inclusion of multiple parameters does not seem to be necessary. Therefore, contrast-enhanced sequences may be omitted as BCa patients regularly suffer from renal insufficiency.
Limitations: Besides a small sample size, the main limitation of this study is the observational character that did not investigate the effect of VI-RADS on clinical decision making.
Ethics committee approval: The study protocol was approved by the Ethics Committee of the Medical University of Vienna.
Funding: No funding was received for this work.

RPS 1707-10 09:18
Diffusion tensor imaging (DTI) images + T2-weighted 3D CUBE sequences: a potential additional tool to mpMRI in differentiating non-muscle from muscle-invasive bladder cancer on a 3T scanner
D. Fierro, M. Pecoraro, S. Cipollari, R. Campa, V. Salvo, C. Catalano, V. Panebianco*; Rome/IT (fierrodavide852@hotmail.com)*

Purpose: To determine whether the association of diffusion tensor imaging (DTI) sequences + T2-weighted 3D CUBE to the standard mpMRI protocol could aid in differentiating muscle-invasive bladder cancer (MIBC) from non-muscle-invasive bladder cancer (NMIBC).
Methods and materials: 61 patients were enrolled and underwent mpMRI before tumour resection. Exams were performed on a 3T scanner (GE Discovery 750) with a 32 channel BodyCoil, DTI sequences (matrix 100x100, TR:3485, TE:55, Auto InvTime:248, thickness (thk): 3.0 mm, gap: 0.5 mm, field of view (FOV) 26, b value: 0 (2 NEX), 1,000 (4 NEX), 16 directions) and T2-weighted (CUBE) 3D isotropic (matrix: 260x260, TR: Auto, TE:120, thl: 1.4 mm, FOV 26, echo-train-length (ETL):100) were acquired and reconstructed with WorkStation

(FiberTrack program, GE, ADW 4.7). Two radiologists reported the exams, blinded to pathology results. Accuracy was determined using histopathology as a reference standard.
Results: A total of 61 exams were analysed. All NMIBC (n=41) lesions were correctly defined by the DTI + T2-weighted 3D CUBE image set. Overall accuracy of the setting protocol completed by FiberTrack and MultiPlanar reconstructions was 90% to differentiate NMIBC from MIBC.
Conclusion: Association of DTI + T2-weighted 3D CUBE sequences on MpMRI appears to be a reliable staging tool for bladder cancer. With further validation, mpMRI + DTI sequences + T2-weighted 3D CUBE could precede cystoscopic resection, allowing for prompt detection of muscle invasiveness fastening therapeutic pathways.
Limitations: A small sample size in a single institution.

RPS 1707-11 09:24

Evaluation of diffusion kurtosis imaging versus standard diffusion-weighted imaging in the assessment of the pathological grade of clear-cell renal cell carcinoma

J. Cao, B. He, X. Luo, X. Sun*; Zibo/CN (cjf19810629@163.com)*

Purpose: To evaluate the role of diffusion kurtosis imaging in the characterisation of clear-cell renal cell carcinoma compared with standard diffusion-weighted imaging.
Methods and materials: 80 patients with histologically proven ccRCC were evaluated by DKI and DWI on a 3-T scanner. All ccRCCs were classified as grade 1 (n=15), grade 2 (n=22), grade 3 (n=24), and grade 4 (n=19) according to the Fuhrman classification system. Regions of interest were drawn on the maps of the apparent diffusion coefficient, fractional anisotropy, mean diffusion coefficient, mean diffusion kurtosis, axial kurtosis, and radial kurtosis. The differences in DWI and DKI parameters were evaluated and a receiver operating characteristic analysis was performed.
Results: ADC value could be used to discriminate G1 vs G3, G1 vs G4, G2 vs G3, G2 vs G4, and G3 vs G4 ($P < 0.05$), except for G1 vs G2. All the DKI parameters except for FA could be used to discriminate G1 vs G2, G1 vs G3, G1 vs G4, G2 vs G4, and G3 vs G4 ($P < 0.05$), whereas MD, MK, and Kr could discriminate G2 vs G3 ($P < 0.05$). Moreover, ROC analysis showed that the MK values exhibited the best performance.
Conclusion: DKI could provide better performance than conventional DWI in grading ccRCC.
Limitations: The number of ccRCC patients was relatively small. When the lesion is small or there is an unresolved necrotic area in the lesion, the ROI fails to completely avoid the necrotic tissue in the lesion and the results may be biased.
Ethics committee approval: This study was approved by the local institutional review board and informed consent was obtained from all patients.
Funding: No funding was received for this work.

Imaging protocols for renal multiparametric MRI and MR urography: results of a consensus conference from the French Society of Genitourinary Imaging

O. Rouviere*; Lyon/FR (olivier.rouviere@netcourrier.com)*

Purpose: To develop technical guidelines for magnetic resonance imaging aimed at characterising renal masses (multiparametric magnetic resonance imaging and mpMRI) and the bladder and the upper urinary tract (magnetic resonance urography and MRU).
Methods and materials: The French Society of Genitourinary organised a Delphi consensus conference with a two-round Delphi survey followed by a face-to-face meeting. Two separate questionnaires were issued for renal mpMRI and for MRU. Consensus was strictly defined using a priori criteria.
Results: 42 expert uro-radiologists completed both survey rounds with no attrition between the rounds. 56/84 (66.7%) statements of the mpMRI questionnaire and 44/71 (62%) statements of the MRU questionnaire reached a final consensus. For mpMRI, there was consensus that no injection of furosemide was needed and that the imaging protocol should include T2-weighted imaging, dual-chemical shift imaging, diffusion-weighted imaging (use of multiple b-values; maximal b-value: 1000 s/mm²) and fat-saturated single-bolus multiphase (unenhanced, corticomedullary, nephrographic) contrast-enhanced imaging; late imaging (more than 10 minutes after injection) was judged as optional. For MRU, the patients should void their bladder before the examination. The protocol must include T2-weighted imaging, anatomical fast T1/T2-weighted imaging, diffusion-weighted imaging (use of multiple b-values; maximal b-value: 1000 s/mm²), and fat-saturated single-bolus multiphase (unenhanced, corticomedullary, nephrographic, excretory) contrast-enhanced imaging. An intravenous injection of furosemide is mandatory before the injection of contrast medium. Heavily T2-weighted cholangiopancreatography-like imaging was judged optional.
Conclusion: This expert-based consensus conference provides recommendations to standardise magnetic resonance imaging of kidneys, ureter, and bladder.
Limitations: Consensus statements represent a low level of evidence.
The consensus conference did not address MR examinations aimed at evaluating bladder cancer local staging, nor protocol variations in children or pregnant women.
Ethics committee approval: n/a
Funding: This work was funded by the French Society of Genitourinary Imaging (Société Française d'Imagerie Génito-urinaire)

Validation of vesical imaging reporting and data systems in bladder tumours: assessment of muscle invasion

S. H. Kim, H. S. Park, S. H. Cho*; Daegu/KR (warpaludin@gmail.com)*

Purpose: To retrospectively determine the diagnostic values of a VI-RAD score for the detection of muscle invasion in patients with bladder tumours.
Methods and materials: This study included 347 consecutive patients with 339 tumour lesions who were previously diagnosed by CT imaging and subsequently underwent bladder multiparametric MR imaging between January 2015 and March 2019. Lesions level analyses were performed by using an overall score of VI-RADS. Histologic examination of TURBT was used as the reference standard. Two radiologists assessed the diagnostic scores of tumours with muscle invasion by using cutoff values of ≥ 4 and ≥ 3. Cutoff values for VI-RADS scores were estimated from operating points of AUC analyses. Sensitivity, specificity, PPV, NPV, and accuracy were calculated to assess the utility of VI-RADS
Results: The interobserver agreement was excellent for three different MR imaging at the lesion level. T2W and DW imaging had a similar diagnostic accuracy of 79.3% for tumour lesions with muscle invasion compared to the overall score of 80.2%, with a cutoff value of 4. The overall VI-RAD score showed an accuracy of 80.2%, with a cutoff value of ≥ 4, granting a sensitivity of 91.3%, specificity of 76.0%, PPV of 83.3%, and NPV of 78.9%. When we applied an arbitrary overall score of ≥ 3, accuracy was 63.7%, sensitivity was 94.6%, specificity was 43.9%, PPV was 51.6%, and NPV was 63.7%.
Conclusion: VI-RADS has an overall good performance for the diagnosis of tumours with muscle invasion.
Limitations: The current study was a single-centre retrospective study with a small number of participants. As a consequence, a statistical significance was not observed in comparing each result. For these results to be more definitive, prospective studies with larger numbers of patients are required.

Validation of a prospective assessment of the vesical imaging-reporting and data system (VI-RADS) in high-risk non-muscle invasive bladder cancers (NMIBC) candidate for repeated transurethral resection

M. Pecoraro, S. Cipollari, R. Campa, F. Del Giudice, G. Simone, E. de Berardinis, C. Catalano, V. Panebianco*; Rome/IT (pecoraro.martina1@gmail.com)*

Purpose: To prospective validate VI-RADS in NMI-and-MIBC discrimination at TURBT. To identify HR-NMIBCs who could avoid Re-TURBT and to detect those at a higher risk for under-staging after TURBT.
Methods and materials: Patients with a BCa suspicion were offered multiparametric magnetic resonance imaging (mpMRI) before TURBT. According to VI-RADS, a cutoff ≥3 to define MIBC was assumed. TURBT reports were compared with preoperative VI-RADS scores to assess the accuracy of mpMRI in discriminating NMI-and-MIBC. HR-NMIBCs Re-TURBT reports were

compared with preoperatively recorded VI-RADS scores to assess mpMRI accuracy in predicting Re-TURBT outcomes. Sensitivity, specificity, and positive and negative predictive (PPV, NPV) values were calculated for mpMRI performance in patients undergoing TURBT and for HR-NMIBCs candidate for Re-TURBT. ROC curve and K statistics were calculated
Results: 231 patients were enrolled. MpMRI showed a sensitivity, specificity, PPV, and NPV in discriminating NMI-from-MIBC at initial TURBT of 91.9% (95%CI:82.2–97.3), 91.1% (95%CI: 85.8–94.9), 77.5% (95%CI:65.8–86.7), and 97.1% (95%CI:93.3–99.1), respectively. Area under curve (AUC) was 0.94 (95%CI:0.91–0.97). Within HR-NMIBCs (n=114), mpMRI before TURBT showed a sensitivity, specificity, PPV, and NPV of 85% (95%CI:62.1–96.8), 93.6% (95%CI: 86.6–97.6), 74.5% (95%CI: 52.4–90.1) and 96.6% (95%CI: 90.5–99.3), respectively, to identify patients with MIBC at Re-TURBT. AUC was 0.93 (95%CI: 0.87–0.97).
Conclusion: VI-RADS is accurate for discriminating NMI-and-MIBC. Within HR-NMIBCs, VI-RADS could improve the selection of patients' candidate for Re-TURBT in the future.
Limitations: MpMRI cannot yet be adopted for CIS and the sample is small in a single-centre.
Ethics committee approval: Approved by an ethical committee with a waiver of informed consent.

The potential of apparent diffusion coefficient values as an independent marker for tumour aggressiveness in non-muscle-invasive bladder cancer
A. Rahota[1], P. Medan[2], B. Petresc[3], A. Tamas-Szora[2], R. Rahota[1], N. Crisan[2], A. Lebovici[2]; [1]Oradea/RO, [2]Cluj/RO, [3]Tg. Mures/RO

Purpose: To determine whether the apparent diffusion coefficient (ADC) measured from diffusion-weighted imaging reflects quantitative information of the histological grading and clinical aggressiveness of non-muscle-invasive bladder cancer.
Methods and materials: We prospectively enrolled 25 bladder tumours that have undergone 1.5T MRI DW images using b-values of 0, 50, and 800 s/mm2 in axial and sagittal planes. ADC values and their relationship with histological factors were measured for each lesion. The pathology report was considered a gold standard diagnosis.
Results: 14 lesions were low grade (LG) and 11 high grade (HG). 11 lesions were staged as pTa and 14 as pT1. The mean ADCs of LG and HG tumours were 1.25 × 10−3 mm2/s, respectively, 0.80 × 10−3 mm2/s, with a difference that was statistically significant (p<0.001). The cut-off value in the receiver operating characteristic (ROC) curve for differentiating LG and HG according to ADC values was 0.87 × 10−3 mm2/s (Se=72.7%, Sp=100%), with an area under curve (AUC) of 0.90. The mean values of ADC of pTa and pT1 tumours were 1.24 × 10−3 mm2/s and 0.80 × 10−3 mm2/s, respectively (p<0.001). No significant difference was found among the values of ADCs of axial versus sagittal acquisitions for tumours located on the lateral walls (1.12 × 10−3 mm2 /s vs. 1.21 × 10−3 mm2/s, p=0.56), or for tumours located on the inferior and superior walls (1.15 × 10−3 mm2/s vs 1.08 × 10−3 mm2/s, p=0.56).
Conclusion: DW imaging with ADC measurement could become a novel non-invasive method for predicting tumour aggressiveness in bladder cancer.
Limitations: A preliminary study and small sample size.
Ethics committee approval: All patients gave written informed consent.

Performance of HRCT temporal bone in the evaluation of non-otologic anatomical variations in temporal bone and their implications in procedure planning of cochlear implant surgery: a prospective study
S. Agarwal, A. Prakash, N. Mannan, M. Grover; *Jaipur/IN (srishtiagarwal243@gmail.com)*

Purpose: Cochlear implantation is the recommended treatment for patients presenting with severe to profound pre- or post-lingual sensorineural hearing loss. Imaging plays a pivotal role in the selection of candidates. A pre-operative knowledge of variant anatomy helps in the planning of the surgical approach and aids in identifying potential complications.
Methods and materials: Patients suffering from profound to severe sensorineural hearing loss with the candidacy for cochlear implantation were evaluated by high-resolution CT of the temporal bone (HRCT). A total of 100 cases were referred from July 2018 to February 2019 and were included in the study after taking patient consent. Many anatomical variants were observed including mastoid pneumatisation, level of middle cranial fossa dura, Korner's septum, mastoid emissary vein, sigmoid sinus and jugular bulb position, bony facial canal, position of mastoid segment of facial nerve canal with respect to round window for visualisation of round window during surgery and alignment of cochlear basal turn with respect to axis of internal carotid artery canal for round window accessibility.
Results: The pre-cochlear implant imaging had a sensitivity of 97.22% and diagnostic accuracy of 90% in identifying accessibility of round window when correlating with intra-operative findings. Surgeon acceptability was a highlight of this study.
Conclusion: Pre-cochlear implantation imaging in addition to performing the accepted role of imaging of the middle and internal ear anatomy is also crucial in the identification of various non-otologic landmarks which affect procedure planning and possible complications. Attention to these small but significant details can greatly improve surgical outcome.
Limitations: There is possibility that changes could have happened in the period between imaging and surgery which was appreciated in surgery and was absent during imaging.

Noise-optimised virtual monoenergetic imaging of dual-energy CT: effect on contrast agent artifacts reduction on carotid CTA examination
J. Fu, Y. Zeng, J. Zhang; *Shanghai/CN (kdidjs_fu@163.com)*

Purpose: Artefacts of contrast agent in the subclavian vein often affect the display of cervical arteries at the corresponding level. We aimed to evaluate the effects of noise-optimised virtual monoenergetic imaging (VMI+) reconstructions on reducing these artefacts, compared to traditional virtual monoenergetic imaging (VMI) and linearly blended (F_0.6) reconstructions in patients underwent carotid CTA and recommend a better energy level to show calcified plaque.
Methods and materials: Ten patients who underwent carotid CTA were evaluated retrospectively. Images were reconstructed with F_0.6, VMI and VMI+ at 20-keV intervals from 40 keV to 140 keV. Attenuation and noise were measured in the cervical arteries at the worst level obstructed by the contrast agent artefacts of each patient. The artefact index (AI) and iodine SNR were calculated.
Results: The AI values for the cervical arteries were lowest in the 140keV VMI+ series, which were lower compared to all the VMI and F_0.6 images (all p<0.029), but showed no significant differences compared to the 120keV VMI+ series (p=0.684). The SNR was highest in the 40keV VMI+ series, and there were no significant differences compared to the highest SNR in the VMI images and F_0.6 (P≥0.529), even compared to the 60-120keV VMI+ (p≥0.052).

Conclusion: DECT with 120keV VMI+ efficiently reduced artefacts of contrast agent without affecting image quality of carotid CTA, and 120keV can be used as an additional energy level in the VMI+ reconstruction to better show calcified plaques in the cervical arteries affected by the artefacts.
Limitations: A small number of patients with severe artefacts of contrast agent on carotid CTA were obtained.
Ethics committee approval: This was approved by the institutional review board of Huashan Hospital of Fudan University.

Ultra-high frequency ultrasound (UHFUS) of the minor salivary gland in patients with Sicca syndrome
A. Marcucci, S. Vitali*; Pisa/IT*

Purpose: The aim of this study was to assess the usefulness of ultra-high frequency ultrasound (UHFUS), with frequencies up to 70 MHz and resolution up to 30 µm, for the examination of the minor salivary glands in primary Sjögren's syndrome (pSjS). In particular we assessed the diagnostic accuracy of UHFUS, and the improvement of bioptic sampling under UHFUS guidance.
Methods and materials: Seventy-eight patients with Sicca syndrome suspected secondary to pSjS (72 females and 6 males) with a mean age of 56 years (standard deviation=±15 years) were enrolled. The following UHFUS parameters were evaluated: glands distribution, parenchymal inhomogeneity (score 0-3, from absent inhomogeneity to evident), fibrosis, and vascular pattern and degree of vascular intensity (by means of echo color-Doppler analysis). The minor salivary gland of the lower lip with more significant UHFUS abnormalities was marked with a dermographic pen and underwent biopsy for calculation of the focus score (FS).
Results: In 38/78 cases (48.7%) pSjS was diagnosed on the basis of ACR/EULAR criteria. Glands with UHFUS score≥1 were considered suggestive of pSjS (sensitivity=100%, specificity=26.7%, NPV=100% and PPV=50%). We found a good correlation between the FS and the following UHFUS parameters: lateral inhomogeneity (r=0.532), central inhomogeneity (r=0.496), central fibrosis (r=0.398). Under UHFUS guidance, the percentage of adequate bioptic samples increased from 62.5% in 2017 to 83.6% in the period 2018/2019.
Conclusion: UHFUS findings accurately predict the FS. Moreover, this modality provides reliable guidance for biopsy. The 100% negative predictive value makes UHFUS suitable as a screening tool for pSjS, with the potential to avoid unnecessary biopsies.
Limitations: The small number of patients enrolled.
Ethics committee approval: Ethics committee approval was obtained.
Funding: No funding was received for this work.

Response evaluation of choroidal melanoma after brachytherapy using diffusion-weighted magnetic resonance imaging (DW-MRI): preliminary findings
F. Bitencourt[1], A. Bitencourt[1], J. D. O. Souza[1], N. Neves[2], M. Chojniak[1], R. Chojniak[1]; [1]São Paulo/BR, [2]Salvador/BR (almirgvb@yahoo.com.br)

Purpose: To evaluate the role of diffusion-weighted magnetic resonance imaging (DW-MRI) in the evaluation of patients with choroidal melanoma at the time of diagnosis and in the evaluation of therapeutic response after brachytherapy.
Methods and materials: We performed a prospective, unicentric study approved by the research ethics committee, which included patients with choroidal melanoma and indication for brachytherapy. Three DW-MRI examinations were proposed for each patient, one before and two after treatment. The apparent diffusion coefficient (ADC) value was calculated on DW-MRI and compared with local tumour control assessed by ophthalmologic follow-up.
Results: From 07/2018 to 06/2019, 19 patients were included, of which 13 underwent follow-up examinations. Patients' ages ranged from 24 to 78 years and 52.9% were male. At the ocular ultrasound, the mean tumour thickness and diameter were 6.3 mm and 11.5 mm, respectively. At initial MRI, most tumours presented high or intermediate signal at T1 (82.3%) and a low signal at T2 (70.6%). Two patients (15.4%) showed signs of tumour progression during follow-up. There was no statistically significant difference in tumour size between MR before and after treatment, however, there was a significant reduction in mean ADC in patients with progression (p = 0.02).
Conclusion: DW-MRI has shown to be useful in assessing patients with choroidal melanoma and mean ADC values can be used for response assessment, allowing early identification of patients at risk for progression after brachytherapy.
Limitations: This study was limited by the small number of cases.
Ethics committee approval: The IRB approval was obtained.
Funding: This study was funded by the São Paulo Research Foundation - FAPESP (grant n. 2016/05967-5).

The evaluation of the maculopathy using dynamic contrast-enhanced MRI in patients with proliferative diabetic retinopathy
Z. Chen, M. Liu, L. Ma*; Beijing/CN (yyqf@hotmail.com)*

Purpose: To evaluate the macular change in the patients with diabetic retinopathy using dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) technique.
Methods and materials: Twenty patients with diabetic retinopathy (DR) and 20 normal controls (NC) were included. The fast spoiled gradient recalled sequence was used to perform dynamic contrast T1WI enhancement on 3.0T MR system. The macular region, optic papilla and nasal retina were performed with quantitative DCE-MRI evaluation using Omni-Kinetics software.
Results: The maximal concentration, the area under the concentration-time curve (AUCconcentration-time) and maximal slope of macular region were significantly higher in DR [0.270 (0.03,1.20) mmol/100ml, 2.71 (0.04,9.91) mmol*min and 0.38 (0.06,3.18) mmol/min, respectively] than that [0.169(0.03,0.72) mmol/、1.25 (0.13,10.41) mmol*min and 0.245 (0.06,1.34) mmol/min] in NC (U value = 515.00 and P value = 0.080, U value = 433.00 and P value = 0.000, and U value = 563.00 and P value = 0.023, respectively). The receiver operating characteristic curve (ROC) analysis demonstrated that the area under AUCconcentration-time was 0.729±0.058 with the cut-off value 1.479 mmol*min (sensitivity 80.00% and specificity 62.50%) for macular region.
Conclusion: The quantitative DCE-MRI technique could be used to evaluate the maculopathy associated with the diabetic retinopathy.
Limitations: The limits of this study are that the region of interest (ROI) in the retinochoroidal complex, the enhanced concentration of choroid was also included in the regions, would not truly reflect retinopathy entirely based on the current MRI technique.
Ethics committee approval: This study was approved by the Chinese PLA General Hospital institutional review board, and written informed consent were obtained from all subjects.
Funding: No funding was received for this work.

The relationship of severity of migraine and the optic nerve sheath diameter measured by ultrasonography in patients admitted to an emergency department
I. Kanbur[1], H. Topacoglu[2]; [1]Vienna/AT, [2]Istanbul/TR (drinciferkanbur@gmail.com)

Purpose: ONSD (optic nerve sheath diameter) measured by ultrasonography would be different in patients with migraine with aura than in patients with migraine without aura.
Methods and materials: 49 patients were enrolled. Patients were excluded from the study if they were haemodynamically unstable, needed emergency intervention, had an anatomical eye abnormality, had an eye disease that increased the ONSD or had a headache secondary to organic disease. Patients were assessed for headache type according to the criteria determined by the International Headache Society (IHS). The Siemens Acuson P500 portable ultrasound device in ocular imaging mode with a 10-MHz surface tissue probe was used bedside for the evaluation of the ONSD and eye segment diameter. The ONSD was scanned in the sagittal and transverse planes. Additionally, the eye segment diameter measurements were performed on both eyes. All measurements were repeated three times and then the mean value was recorded.
Results: There was no significant difference in the eye segment mean diameters between patients with and without pulsating pain (p > 0.05). There

was also no significant difference in the eye segment mean diameters between patients with and without aura using the Mann–Whitney U-test ($p > 0.05$).
Conclusion: In this study, we found that there was a statistically insignificant increase in the ONSD in patients with migraine with aura compared to the patients without aura and also in patients with pulsating pain compared with patients without pulsating pain. We could not find any differences in the transverse diameter, anteroposterior diameter, anterior camera depth, and eye globe volume in patients with and without aura.
Limitations: This study is limited by the following: the small number of participants, no control group, no follow-up measurements, and the inclusion of just migraine patients.
Ethics committee approval: n/a
Funding: No funding was received for this work.
Author Disclosures:
I. Kanbur: nothing to disclose

Volumetric analysis of the maxillary, sphenoid and frontal sinuses in computerised tomography: a comparative study using volume rendering in patients of the Hospital Universitario in Monterrey, Mexico
I. A. Garza Rico, R. A. Cuéllar Lozano, R. Pinales Razo, N. G. Jasso Ramirez*; Monterrey/MX (dra.ingridgarza@gmail.com)*

Purpose: To measure the volume and measurements of the maxillary, sphenoid and frontal sinuses and in healthy Mexican patients, using computed tomography (CT) scans.
Methods and materials: A retrospective, case series study in a single academic centre, CT scans of 210 subjects, 10 of every age, between 0 and 20 years of age, performed between January 2016 and November 2017 in the Hospital Universitario of Monterrey, Mexico. A comparative analysis of the volume and dimensions of the paranasal sinuses was performed using multiplanar reformating and volume rendering with segmentation. Patients with prior history of trauma, surgery, and pathology of the paranasal sinuses were excluded. The study population was subdivided by gender and age.
Results: A total of 210 CT scans were analysed, 104 (49.5%) males and 106 (50.5%) females. The groups were subdivided by age (<5, 6-10, 11-15 and >16 years). The largest volumes were reached by 16 to 20 years of age. In the 6-10 age group, the females had larger volumes than the males. The males had a tendency to present larger volumes in general. There is a high correlation in between the volume of sinus and its contralateral r (0.01) and there is also a significant relation of the sinus volume and age Z (<0.004).
Conclusion: There is a clear volumetric correlation according to age and gender, there is a direct relation between a sinus and its contralateral homologous. The expected volume development can influence clinical decision making in this age group.
Limitations: The normal variants of the paranasal sinuss were not part of the study design.
Ethics committee approval: This study was approved by the Ethics Comitee of the Hospital Universitario.
Funding: No founding was received for this work.

Role of magnetic resonance imaging in patients with temporomandibular joint pain
P. M. A. D. Mohamed Abouelhoda, R. A. M. A. Helal, A. A. Megahed*; Cairo/EG (bosi_123@hotmail.com)*

Purpose: To assess the role of MRI in the assessment of patients suffering from temporomandibular joint pain presented to the El-Demerdash Hospital.
Methods and materials: A cross-sectional study is done on 50 patients presented to El-Demerdash hospital presented by temporomandibular joint (TMJ) pain. MRI was done on our 1.5 T machine with the following conventional sequences: axial T1 images sagittal oblique images, oriented along the long axis of the mandible, acquired at closed and open mouth positions, obtained with a fast-spin echo, a PD, and a T2* gradient echo technique. Coronal thin sections of ≤3 mm T2 sequences. Image interpretation was done commenting upon the articular surfaces, articular disc position and morphology, joint space, lateral pterygoid muscle as well as bony abnormalities.
Results: 64% of the cases had TMJ pain due to disc displacement. 18% of the cases had TMJ pain due to arthritis. 6% of the cases had TMJ pain due to fracture. 6% of the cases had TMJ pain due to infection. 4% of the cases had TMJ pain due to tumour. 2% of the cases had TMJ pain due to lateral pterygoid muscle abnormality
Conclusion: MRI is the technique of choice for assessing patients presented with TMJ pain identifying its different pathologies. Having a systemic pattern in image interpretation is important for the radiologist to detect early signs of TMJ dysfunction, thereby avoiding its progression to an irreversible phase.
Limitations: The study was done on a small number of patients. The positioning of the patient during the imaging was limited due to severe pain and limited open-mouth view.
Ethics committee approval: The research ethics committee in the El-Demerdash Hospital approved the research with informed consent form for patients or their parents who are invited to participate in the research.
Funding: No funding was received for this work. Agreement to reduce the MR price was provided.

Normal thyroid stiffness in healthy adults using real-time shear wave and strain elastography and factors that influence the measurement of stiffness
M. Z. Mohammad Zakir[1], P. Chatterjee[2], R. Ravikumar[3]; [1]Nagpur/IN, [2]Guwahati/IN, [3]Chennai/IN (drmohammadzuber@gmail.com)

Purpose: Elastography is a non-invasive technique to determine tissue stiffness. Elastography estimation is of two types qualitative (compression) and quantitative (shear wave or ARFI) method. The aim of this study is to define a normal range of thyroid stiffness in healthy individuals using the above methods. Also, our objective is to determine various factors affecting in determining the elastography values.
Methods and materials: In our study 812 healthy subjects underwent the examination of the stiffness of the thyroid gland and various factors like age, gender, position during the test, BMI, size of ROI, depth of ROI etc which affect the stiffness measurement were studied. In the strain elastography (compression) the red colour coding was taken as stiffer areas and blue as normal tissue; green was intermediate tissue type.
Results: The mean value of ARFI (shear wave or quantitative) in the 812 subjects were 1.32 +/- 0.55 m/s. In the strain elastography (compression) all subjects' thyroid gland demonstrated blue colour coding representing normal parenchyma. The stiffness was found more in the elderly and with higher BMI subjects. The values were more consistent when measured in the mid-segment of the lobe of the thyroid gland. The values were slightly higher in female subjects. The size and depth of ROI do not affect the measurement.
Conclusion: The sonoelastography of the thyroid gland is an important non-invasive tool to assess the stiffness of thyroid gland in pathological conditions. The factors which affect the elastography measurement should be avoided or considered while measuring the elastography values. Elastography is a non-invasive technique to assess the tissue stiffness and to differentiate normal and abnormal areas in the tissue.
Limitations: The single-centre study design limited this study.
Ethics committee approval: n/a
Funding: No funding was received for this work.

MDCT evaluation of neck masses in adults
A. Kotwal, A. N. Kamble*; New Delhi/IN*

Purpose: To study the role of multi-detector computed tomography (MDCT) in the evaluation of neck masses in adults in the Lady Hardinge Medical College, New Delhi. To correlate MDCT findings with clinical/perioperative/pathological follow-up findings whenever possible.
Methods and materials: The hospital-based descriptive observational study conducted from November 2015 to March 2017 in the department of radio-diagnosis. The study population was adults (>18 years) with neck masses. The sample size was 33 patients. The inclusion criteria was the following: age ≥ 18 years with clinically detected neck masses and neck masses detected on ultrasonography who were referred for MDCT and incidentally diagnosed neck masses by MDCT. The exclusion criteria were the following: a history of trauma of neck area and pregnancy. The study instruments were clinical proforma and PHILIPS BRILLIANCE 40 slices multi-detector CT. The methodology used included clinical evaluation and CT. Plain and contrast-enhanced scans using non-ionic contrast media were performed sequentially from the base of the skull to the 4th thoracic vertebra. Multi-planar reconstruction was created.
Results: Nodal masses were the most common masses (39.4%). These included metastatic (27.27%), lymphomatous (6.06%), tubercular adenopathy (6.06%). Non-nodal masses constituted 60.6%, included salivary gland lesions

(30%), thyroid masses (30%), masses of developmental origin (15%), neurogenic (10%), vascular (5%), mesenchymal origin (5%) and inflammatory masses (5%). 84.6% of the nodal masses were malignant, 15.3% were benign. 25% of the non-nodal masses were malignant, 75% were benign. In total, 48.48% had malignant lesions and 51.5% of the cases had benign lesions.
Conclusion: MDCT ensure anatomical localisation, characterisation and lesion extent of the neck masses.
Limitations: This study was performed as a single centre study and is limited by small sample size.
Ethics committee approval: The study was approved by the institutional ethical committee and written informed consent was taken by each patient.
Funding: This study was funded by our institute.

Neurologic dysphagia: does the percutaneous endoscopic gastrostomy (PEG) treatment really decrease the incidence of aspiration pneumonia?
L. Perrucci, M. Stantieru, M. Giganti, R. Galeotti*; Ferrara/IT (dott.perrucciluca@gmail.com)*

Purpose: Our goal has been to determine if PEG treatment determined a reduction of pneumonia cases in a population with neurologic functional dysphagia.
Methods and materials: 20 patients with neurogenic dysphagia have been retrospectively examined. In 13 PEG-treated patients were evaluate the thorax x-rays and CT to find signs of pneumonia. The observation period is between 500 days before and after the endoscopic surgical procedure. Other seven patients were treated only with rehabilitation; the same evaluation was referred to the radiographic dynamic study of the swallowing (DSS - also called a videofluoroscopic study of the swallowing, VFSS). All 20 patients performed a DSS to confirm or exclude the presence of aspiration, this latter only determining the aspiration nature of pneumonia. The exact Fisher test was applied to each group and subgroup.
Results: In the first group analysed of the 13 PEG-treated patients, 7 presented pneumonia before the procedure and the prevalence increased of 8/13 after it, six of whom did not present before. Regarding those ones without aspiration at DSS(low-risk for pneumonia) presented an increase of the cases from 3/8 to 5/8. In the remaining five patients with aspiration (high-risk pneumonia with the burden of aspiration pneumonia defined at DSS) the ratio decreased from 4/5 to 3/5. No significant p-value has merged at the Fisher tests. In the second group of seven patients, who were not treated with PEG the Fisher test on pneumonia cases was not significant as well, but the prevalence of pneumonia was higher than in the other subgroups (6/7).
Conclusion: The DSS helped to distinguish patients with aspiration, and therefore with aspiration pneumonia, where the PEG treatment determined a reduction of pneumonia cases. In the other subgroups the prevalence of pneumonia increased.

Comparative efficacy of neck ultrasonography, ^{99m}Tc Sestamibi scan and ^{18}F- Choline PET/CT in the preoperative localisation of suspected cases of parathyroid adenoma in primary hyperparathyroidism
T. Neeliyath Thazha Kuni[1], A. Sood[2], R. Kr[1], S. K. Bhadada[2], B. R. Mittal[2], A. Behra[2], U. N. Saikia[2], D. S. Rao[3]*; [1]Calicut/IN, [2]Chandigarh/IN, [3]Detroit, MI/US (DRTHANSEER@GMAIL.COM)*

Purpose: This study was conducted to compare the effectiveness of ultrasonography of the neck, ^{99m}Tc-sestamibi and ^{18}F-fluorocholine PET/CT imaging in the preoperative localisation of parathyroid lesions in patients with primary hyperparathyroidism.
Methods and materials: Fifty-four patients of PHPT were included in this prospective study who underwent preoperative localisation of the parathyroid lesion(s) using three diagnostic modalities followed by surgery. The sensitivity, positive predictive value (PPV) and accuracy of the three imaging procedures to accurately detect abnormal parathyroid glands were determined using histopathology as the gold standard.
Results: FCH PET/CT detected 52 out of 54 patients and 52 out of 56 lesions with histopathologically proven parathyroid adenomas on patient-based and lesion-based analysis respectively. Preoperative USG, MIBI and FCH PET/CT localised abnormal parathyroid gland(s) in 39 (72.2%), 43 (79.6%) and 54 (100%) patients respectively. The sensitivity and PPV were 69.3% and 87.1% for USG, 80.7% and 97.6% for MIBI, and 100% and 96.3% for FCH PET/CT. The accuracy was 62.9%, 79.6% and 96.3% for USG, MIBI and FCH PET/CT respectively in the patient-wise analysis. In six patients with ectopic lesions, FCH PET/CT demonstrated higher sensitivity and accuracy than MIBI and USG (100% vs 66.6% and 16.7% respectively).
Conclusion: Among the three imaging techniques tested simultaneously, FCH PET/CT was superior for accurate preoperative localisation of parathyroid adenomas, especially for ectopic or small parathyroid lesions.
Limitations: Various statistical measures like specificity, negative predictive value and serum PTH cut off values for FCH PET/CT could not be calculated in our study, as none of the patients was negative on FCH PET/CT imaging.
Ethics committee approval: The ethics committee approval was obtained.
Funding: No funding was received for this work.

Role of neck imaging reporting and data system (NI-RADS) in the prediction of local and regional recurrence of head and neck squamous cell carcinoma
T. Taha, M. M. M. Ashour, H. A. K. Abdel Hameed, Z. M. Abdel Hafeez, A. S. Abdelrahman*; Cairo/EG (manar.ashour@gmail.com)*

Purpose: To assess the diagnostic performance of the ACR NI-RADS.
Methods and materials: 116 follow-up scans for 55 patients treated from primary HNSCC were included in combined retrospective and prospective study that was conducted in Ain-Shams University Hospitals. Scans timings followed our institution protocol; the first follow-up performed eight weeks after finishing treatment. A choice between CE-CT/MRI or PET-CT determined by the clinical scenario. Scans were reported using the ACR NI-RADS template, scores were assigned to each scan; one for the primary tumour site and one for neck nodes. The assigned NI-RADS scores were correlated to patients' outcomes according to our gold standard: tissue pathological examination and/ or follow-up scans, with follow-up duration that extended for twelve months, except for two patients. We calculated the rate of disease recurrence for each score. We compared the diagnostic performance of the different NI-RADS templates for CE-CT; PET-CT and CE-MRI. We also assessed the diagnostic performance of the templates' imaging findings describing the primary tumor site morphological changes, enhancement, and FDG activity, and describing the neck nodes correlated to outcome. Data analysis was done by IBM SPSS (V.25.0, IBM Crop., USA, 2017-2018).
Results: We had 232 targets for primary tumour sites and for lymph nodes. Tumour recurrence occurred in 53 targets. Recurrence rates for each NI-RADS category. A significant correlation between template morphological and enhancement findings and patients' outcomes at the primary site and LNs. PET/CT template had the highest accuracy, sensitivity, and specificity.
Conclusion: The performance of the ACR NI-RADS reporting system is excellent with a good correlation with the outcome.
Limitations: This study is limited by the sample volume and time period.
Ethics committee approval: The ethics committee approval and written informed consent were obtained.
Funding: No funding was received for this work.

MyT3 17-14 09:22
A comparative study for diagnostic performance of shear wave elastography and diffusion-weighted MRI in cervical lymph nodes
V. S. Öztürk, E. Ertekin*; Aydin/TR (md.suhaozturk@gmail.com)*

Purpose: The aim of this study was to investigate the potential diagnostic value of point shear wave elastography (pSWE) and the contribution of concurrent diffusion-weighted MRI to diagnostic performance prospectively in patients with cervical lymphadenopathy.
Methods and materials: 188 cervical lymph nodes of 144 patients were included in the study. All patients with or without an underlying malignancy were included in the study and all lymph nodes were evaluated before the treatment or histopathological sampling. US characteristics were recorded, stiffness and

ADC values of lymph nodes were measured. Lymph nodes were divided into benign and malign groups with histopathological findings, clinical and sonographic follow-up.
Results: Short axis, hilus morphology, vascularisation patterns, pSWE, and ADC values were significant parameters in logistic regression tests between the two groups. The median stiffness of malign nodes were higher and the average ADC values were lower than others also the lowest ADC values were measured in lymphoproliferative disorders (p<0.001). Area under the curve values for pSWE and diffusion MRI were 0.846 (95% CI, 0.789-0.903), 0.796 (95% CI, 0.725-0.868), respectively. Tissue stiffness had the highest diagnostic accuracy with 80.3%. Accuracy rate increased to 87.2% from 83.5% when the pSWE was combined with the conventional US. No differences were detected when the DWI findings were added to these.
Conclusion: The use of pSWE combined with B-mode US may be sufficient for the differentiation of lymph nodes and will reduce the number of biopsies. The main role of DWI in cases which underwent ultrasonography, may be specific to lymphoproliferative disorders rather than lymph node characterisation.
Limitations: Study group was heterogeneous and not all cases had pathological evaluation.
Ethics committee approval: The ethics committee approval and written informed consent were obtained.
Funding: No funding was received for this work.

Role of magnetic resonance apparent diffusion coefficient in assessment of solitary thyroid nodule
E. H. A. Emara[1], H. Mansour[2], A. Bessar[2], I. Lebda[2]; [1]*Kafr El-Shaikh/EG,* [2]*Zagazig/EG (emademara85@yahoo.com)*

Purpose: To evaluate the role of apparent diffusion coefficient values in differentiating between malignant and benign solitary thyroid nodules and its correlation with histopathological results as the reference standard.
Methods and materials: 30 patients with solitary thyroid nodules were included and evaluated by ultrasound, colour Doppler ultrasound, conventional magnetic resonance imaging (MRI), MRI with diffusion-weighted imaging (DWI-MR) using b-values (500, 1000 mm^2/s) with ADC value measurement. Fine needle aspiration was done after DW-MRI to avoid affecting diffusion characters of the nodules. Histopathological examinations were done for all cases after surgery and correlated with the imaging finding.
Results: 24 nodules were benign (12 adenomatous hyperplasias, nine follicular hyperplasias, and three solitary nodular goiters) and six nodules were malignant (three papillary carcinoma and three follicular carcinoma). The mean ADC value of benign thyroid nodules (2.1± 0.2× 10–3 mm^2/s – 1.87± 0.3× 10–3 mm^2/s) was statistical significance higher than malignant ones (1.06± 0.2× 10–3 mm^2/s - 0.970.3× 10–3 mm^2/s) using b-values 500, 1000 mm^2/s (P=0.001 and 0.001) respectively. The mean ADC value of benign and malignant nodules done using b-values 1000 mm^2/s was statistical significance higher than using b-values 500 mm^2/s (P=0001). A cut-off ADC value of (1.5) has been suggested as a reference point to differentiate benign from malignant nodules with (83.3 % sensitivity, 96.0% specificity, 83.3 % PPV and 96.02% NPV, P=.001) using b-values 500 mm^2/s and (100 % sensitivity, 100% specificity, 100% PPV and 100% NPV, P=.001) using b-values 1000 mm^2/s.
Conclusion: ADC value calculation is a good quantitative measurement that can differentiate benign from malignant solitary thyroid nodules with recommendable b-value 1000 mm2/s.
Limitations: This study is limited by the motion artefact, a small number of patients and difficult to detect nodules < 5mm.

MyT3 17-16 09:30
Preoperative assessment of extrathyroidal extension of papillary thyroid carcinomas by ultrasound and magnetic resonance imaging: a comparative study
S. Hu[1], X. Wang[2]; [1]*Wuxi/CN,* [2]*Zhenjiang/CN (hsd2001054@163.com)*

Purpose: The purpose of this study was to assess the diagnostic performance of preoperative ultrasonography (US) and magnetic resonance imaging (MRI) for the prediction of extrathyroidal extension (ETE) in patients with papillary thyroid carcinoma (PTC) and to compare the diagnostic performances of US and MRI for predicting ETE.
Methods and materials: This retrospective study was approved by our institutional review board. Preoperative US and MRI were performed for 225 patients who underwent surgery for PTCs between May 2014 and December 2018. For each case, the US and MRI features of ETE were retrospectively and independently investigated by two radiologists. The diagnostic performance of US and MRI, including their sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for ETE, as well as their accuracy in predicting ETE was analysed.
Results: US showed higher sensitivity and NPV than MRI in the prediction of minimal ETE (87.5 vs 71.3, p=0.006 and 76.2 vs 61.7 p=0.046, respectively). MRI showed higher sensitivity than US for assessing extensive ETE (85.4 vs 66.7, p=0.005). The specificity and PPV of MRI were significantly higher than those of US (p=0.025 and p=0.025, respectively) for assessing overall ETE.
Conclusion: Preoperative US should be used as the first line of predicting minimal ETE and MRI should be added to assess assessing extensive ETE. Compared with US, MRI has higher specificity and PPV in detecting overall ETE of PTC.
Limitations: Selection bias may have existed.
Ethics committee approval: This retrospective study was approved by the institutional review board and written informed consent was waived.
Funding: No funding was received for this work.

Advanced protocol of MSCT data post-processing in orbital trauma
O. Pavlova, N. S. Serova, D. Davydov*; Moscow/RU*
(dr.olgapavlova@gmail.com)

Purpose: To establish the advanced diagnostic protocol of MSCT data postprocessing in patients with orbital trauma in order to select the correct treatment tactics and provide optimal preoperative planning.
Methods and materials: A total of 107 patients with orbital trauma (100%) were admitted to the hospital on the 1-2 day after the injury. MSCT was performed using Canon Aquilion One 640, data postprocessing was performed using workstation Vitrea Core. The analysis of MSCT data included standard visualisation of bone and soft tissue injury of orbital structures as well as developed techniques including orbital volume measurements, evaluation of inferior orbital wall defects, analysis of globe position and assessment of periorbital soft tissue density.
Results: Postprocessing of MSCT data according to the developed techniques compared to the standard visualisation of bone and soft tissue injury allowed to reveal additional increased traumatic orbital volume in 21 patients (19%); additional enophthalmos in 9 patients (8%); determination of 4 types of inferior orbital wall defects: small inferior orbital defects (n=18; 17%), moderate defects (n=31; 29%), severe defects (n=37; 35%) and total defects (n=20; 19%) as well as detailed assessment of periorbital soft tissue density: oedema (n=60; 56%), haematoma (n=10; 9%), atrophy (n=28; 27%), no changes (n=9; 8%), p<.001.
Conclusion: The advanced techniques of orbital volume measurements, inferior orbital wall defects evaluation, analysis of globe position and assessment of periorbital soft tissue density statistically significantly increased the efficiency of MSCT data analysis in patients with orbital trauma in order to define the correct treatment tactics.
Limitations: No limitations were identified.

Clinical value of mobile CT head examination in patients with intensive care unit
P. Jin, C. Xia, Z. Li*; Chengdu/CN*

Purpose: To investigate the timeliness, economy, radiation dose and clinical value of mobile CT head scan in intensive care patients.
Methods and materials: The clinical data of 80 patients with progressive intracranial haemorrhage were analysed retrospectively, mobile CT and conventional CT examination were performed in each of 40 cases. On two groups of a bleeding area of image quality was evaluated by two senior radiologists and records of two patients completed the inspection time, radiation dose and statistical analysis of the results.
Results: All patients were successfully completed by a CT head scan. The time required for a mobile CT group examination was (9.21±2.13 min), significantly lower than that of the normal group (47.43±7.10 min), the difference was statistically significant. The effective radiation dose was (1.52±0.00 mSv), lower than the normal group (1.90±0.40 mSv), the difference was statistically

significant. Two groups of bleeding area image quality by which difference was not statistically significant. The examining flow of mobile CT group was reduced three links and three medical staff than the normal group.
Conclusion: Mobile CT examination has higher timeliness and reduces the risk of mobile CT scanning in intensive care patients, saved labor cost and reduced radiation dose, could be better served for the ICU patients who had head CT examining needs.
Limitations: In this study, the body mass index, age and patients were not quantitatively analysed before or after surgery, and further studies will be conducted in the follow-up work.

Role of diffusion tensor imaging in the evaluation of patients with cervical spondylotic myelopathy: a cross-sectional study
V. S. Arunachalam, S. Saxena, R. Dev, P. Sharma, U. Chauhan, S. Sharma, N. Chatterjee*; Rishikesh/IN (drvenkat07@gmail.com)*

Purpose: To ascertain any correlation of diffusion tensor imaging (DTI) parameters - fractional anisotropy (FA) and apparent diffusion coefficient (ADC) with standard MR findings and clinical severity.
Methods and materials: Patients presenting with cervical myelopathy to neurosurgery/orthopedic outpatient department and without recent traumatic history, neuroparenchymal pathology or contraindication to MRI and agreeing to undergo MRI were examined with MRI of the cervical spine. In addition to standard MRI sequences for imaging the cervical spinal cord, diffusion tensor imaging based on single-shot EPI with 20 diffusion directions, each encoded with b-values of 0mm2/s and 1000mm2/s was performed in both sagittal and axial planes. Postprocessing of the raw DTI data was done using ready view developed by GE (Advantage4.7). Stenotic and non-stenotic levels were compared with Kang's grading and DTI parameters. Baseline clinical severity was assessed based on modified Japanese Orthopaedic Association (mJOA) score. Using SPSS(ver23), Anova's test was done to assess different Grade individuals. Pearson's correlation of FA with ADC, Kang's grade and mJOA score were calculated.
Results: 43 patients were included in the study. Mean FA values recorded at stenotic (0.346) was less than non-stenotic (0.600) levels. A negative correlation of -0.661 and -0.362 was recorded between FA and ADC and stenotic grading (Kang's), respectively. Level of significance was recorded at 0.013.
Conclusion: Diffusion tensor imaging can serve as a potential tool for understanding pathophysiology thereby complementing anatomical information from standard sequences and aid in prognostication of patients with cervical spondylotic myelopathy prior to surgical and non-surgical management.
Limitations: Changes in DTI parameters were not recorded following treatment. Technical limitations of DTI may be overcome by using HARDI and Q space imaging.
Ethics committee approval: Institutional ethics committee approved the study. Written informed consent was obtained from all patients.
Funding: No funding was received for this work.

Non-contrast-enhanced carotid MRA: clinical evaluation of a novel ungated radial quiescent-interval slice-selective MRA at 1.5T
S. Peters[1], M. Huhndorf[1], J.-K. Ulf[1], I. Koktzoglou[2], R. Edelman[2], J. Graessner[3], M. Both[1], O. Jansen[1], M. Salehi Ravesh[1]; [1]*Kiel/DE,* [2]*Evanston, IL/US,* [3]*Hamburg/DE (Mona.SalehiRavesh@uksh.de)*

Purpose: Non-contrast-enhanced MRA techniques have experienced a renaissance due to the known correlation between the use of gadolinium-based contrast agents and the development of nephrogenic systemic fibrosis and the deposition of gadolinium in some brain regions. The purpose of this study was to assess the diagnostic performance of ungated non-contrast-enhanced radial quiescent-interval slice-selective MRA of the extracranial supra-aortic arteries in comparison with conventional contrast-enhanced MRA in patients with clinical suspicion of carotid stenosis.
Methods and materials: In this prospective study, both MRA pulse sequences were performed in 31 consecutive patients (median age, 68.8 years; 19 men). For the evaluation, the cervical arterial system was divided into 35 segments (right and left side). Three blinded reviewers separately evaluated these segments. An ordinal scoring system was used to assess the image quality of arterial segments and the stenosis grading of carotid arteries.
Results: Overall venous contamination in quiescent-interval slice-selective MRA was rated as “none” by all readers in 84.9% of the cases and in 8.1% of cases in contrast-enhanced MRA (p=0.0001). The visualisation quality of arterial segments was considered good to excellent in 40.2% for the quiescent-interval slice-selective MRA and in 52.2% for the contrast-enhanced MRA (p=0.0001). The diagnostic accuracy of ungated quiescent-interval slice-selective MRA concerning the stenosis grading showed a total sensitivity and specificity of 85.7% and 90.0%, respectively.
Conclusion: Ungated quiescent-interval slice-selective MRA can be used clinically as an alternative to contrast-enhanced MRA without a significantly different image quality or diagnostic accuracy for the detection of carotid stenosis at 1.5T.
Limitations: The number of patients in our single-centre study was relatively small.
Ethics committee approval: The ethics committee approval was obtained (No. D 508/18).
Funding: This study was funded by the National Institutes of Health under award number R01EB027475.

Agreement between consultant radiologists and reporting radiographers in chest radiograph reporting: a consecutive clinical series
N. H. Woznitza[1], A. Devaraj[1], N. Hayes[1], D. Togher[1], N. Arumalla[1], E. Skyllberg[1], B. Ghimire[1], Z. Shah[1], D. R. Baldwin[2]; [1]*London/UK,* [2]*Nottingham/UK (nicholas.woznitza@nhs.net)*

Purpose: To investigate chest radiograph (CXR) reporting by radiographers.
Methods and materials: A prospective, single-site trial. 12-month consecutive CXRs referred from primary care were independently reported by consultant radiologists (CR;n=13) and reporting radiographers (RR;n=3). Respiratory physicians, blinded to the reporter, compared reports for agreement. Discordant cases were reviewed by thoracic radiologists, blinded to the reporter, who reached the index diagnosis and graded report elements (observation, interpretation, recommendations, and usefulness). The number of CR and RR generated CT scans and lung cancers diagnosed were recorded.
Results: 8,685 of 9,136 (95.1%) CXRs were included. Agreement and insignificant disagreement between CR/RR reports occurred in 5,981 (68.9%) and 1,347 (15.5%) of cases, respectively. 1,357 (15.6%) of CR/RR reports had clinically significant disagreement. Thoracic radiology review has been performed for 908 of 1,357 (66.9%) discordant reports. Both reports were correct in 292 (32.2%), CR report correct in 255 (28.1%), RR report correct in 271 (29.8%), and neither report correct in 90 (9.9%). Thoracic radiologists were no more likely to agree with a CR or RR report (p=0.49;CI=-0.03,0.07). RR reports were non-inferior to CR reports for observation (764 vs 768;p=0.787,CI=-0.037-0.029), interpretation (758 vs 763;p=0.742,CI=-0.039-0.028), and recommendations (692 vs 656;p=0.06,CI=-0.003-0.082), and not clinically different for usefulness (870 vs 832;p<0.001,CI=0.02-0.063). 350 CT scans were generated by CRs or RRs; 103 both CR/RR, 149 CR only, and 98 RR only. 31 of 49 lung cancers were diagnosed on a radiology generated CT; n=22 both CR/RR, n=5 CR only, and n=4 RR only (CR PPV=10.7%;RR PPV=12.9%).

Conclusion: CXR reporting by RR appears to be comparable to CR, with similar accuracy and use of further tests.
Limitations: A single-site study with a small number of observers, mitigated by prospective data collection and a large consecutive clinical series.
Ethics committee approval: NHS-HRA:17/LO/0870.

Measuring the cost of convenience: a multi-reader comparison of chest x-rays reported on a smartphone screen versus a medical grade monitor
V. Mahajan, H. Mahajan, A. Sharma, P. Garg, V. K. Venugopal, S. Gupta, M. Barnwal*; New Delhi/IN*

Purpose: Commonly in the developing world, photographs of medical images are sent through WhatsApp to radiologists for reporting in emergency situations with limited availability of PACS and trained radiologists. We studied the risks associated with such practice by replicating this process in a multi-reader chest x-ray (CXR) study.
Methods and materials: 200 CXRs from 4 outpatient imaging centres were pulled from PACS and anonymised and read by 3 radiologists; R1, R2, and R3 having 32-, 15-, and 6-years' experience, respectively. CXRs were read in two phases. In Phase-1 (P-1), photographs of CXRs, viewed on a non-medical screen, were taken using a smartphone (RedMi-Y1, 13MP camera) and sent to radiologists through WhatsApp who also read the images on smartphones (OnePlus-5T, iPhone 6, and RedMi-4). In Phase-2 (P-2), after a 2-week washout period, the radiologists reported the same CXRs on medical-grade monitors (27 inches, NEC). The findings in the CXRs were recorded under the labels: atelectasis, consolidation, infiltration, pneumothorax, oedema, emphysema, fibrosis, pleural thickening, effusion, cardiomegaly, nodule/mass, and normal study. Sensitivity and specificity were calculated for each label from P-1 for individual radiologists using their own findings and from P-2 as ground truth.
Results: Average sensitivity and specificity across all findings were 80% and 97%. The highest average sensitivity was for pleural effusion (84%) and lowest for pleural thickening (15%). The highest average specificity was for pneumothorax and oedema (99% for both), and the lowest for infiltration (94%). Pneumothorax, pleural effusion, consolidation, and mass/nodules were missed in 8, 6, 1, and 2 cases by R1; 3, 14, 3, and 8 cases by R2; and 2, 2, 3 and 12 cases by R3.
Conclusion: Reading CXRs on mobile phones can lead to significant errors.
Limitations: A small sample size.

Extra validation and reproducibility results of a commercial deep learning-based automatic detection algorithm for pulmonary nodules on chest radiographs at tertiary hospital
K. E. Shin, J. S. Park, J. W. Lee, Y. Koo, S. Byun*; Bucheon/KR (sweetperi@naver.com)*

Purpose: To extra-validate and evaluate the reproducibility of a commercial deep learning-based automatic detection (DLAD) algorithm for pulmonary nodules on chest radiographs and to compare its performance with radiologists.
Methods and materials: This retrospective study enrolled 434 chest radiographs (normal to abnormal ratio, 242:192) from 378 patients that visited a tertiary hospital. DLAD performance was compared with two radiology residents and two thoracic radiologists. Abnormality assessment (using the area under the receiver operating characteristics, AUROC) and nodule detection (using jackknife alternative free-response ROC, JAFROC) were compared among three groups (DLAD only, radiologist without DLAD, and radiologist with DLAD). A subset of 56 paired cases, having two chest radiographs taken within a 7-day period, were assessed for intraobserver reproducibility using the intraclass correlation coefficient. Independent characteristics of pulmonary nodules detected by DLAD were assessed by multiple logistic regression analysis.
Results: The AUROC for abnormality detection for the three groups were 0.872, 0.929, 0.963, respectively ($p<0.05$), whereas the JAFROC analysis of nodule detection was 0.912, 0.834, and 0.948 ($p<0.05$). Reproducibility was 0.80, 0.67, and 0.80, which shows an increase in radiologists using DLAD ($p<0.05$). Nodules detected by DLAD were more solid, round-shaped, and well-marginated without masking ($p<0.05$).
Conclusion: Extra validation results of DLAD showed high ROC results and there was a significant improvement in the performance when radiologists used DLAD. Reproducibility by DLAD alone showed good agreement and there was an improvement from moderate to good agreement for radiologists using DLAD.
Limitations: This is a retrospective study, increasing the possibility of selection bias and limiting the ability to demonstrate a cause-and-effect relationship.
Ethics committee approval: The Institutional Review Board approved this retrospective study with a waiver of informed consent.
Funding: No funding was received for this work.

Quantification of regional and temporal lung ventilation in xenon-enhanced dual-energy CT imaging
N. Buls[1], S. Bayat[2], G. van Gompel[1], S. Verbanck[3], E. Invers[3], T. van Cauteren[1], J. de Mey[1]; *[1]Brussels/BE, [2]Grenoble/FR, [3]Jette/BE (Gert.vangompel@uzbrussel.be)*

Purpose: To assess the dynamics of lung ventilation using xenon-enhanced dual-energy CT (Xe-DECT) of an animal in a normal and bronchoconstricted state.
Methods and materials: Six anesthetised New Zealand white rabbits who received Xe-DECT scans using xenon gas as a contrast agent with a concentration of 70% Xe-30% oxygen, administered by mechanical ventilation via tracheostomy. Dynamic DECT scans (Revolution CT, GE Healthcare) were obtained over multiple breathing cycles during a Xe gas wash-in (WI) and wash-out (WO) sequence by performing 15 repetitive acquisitions with a 1,01s interscan delay. In addition, bronchoconstriction was induced by inhaled methacholine (40 mg/ml) and all scan sequences were repeated. Material decomposition was applied to isolate Xe from the image data and parametric ventilation maps were created to quantify Xe concentration in the segmented lungs. We compared the evolution of the regional Xe concentration (mg Xe/mL) in a normal and bronchoconstricted state.
Results: In a normal state, the maximum Xe concentration in the lungs was 1.60±0.45 mg/mL, which was reached after 15.6±6.9 s. During WO, a 50% decrease in Xe concentration was observed after 12.1±1.3s. The parametric maps clearly showed the increase and decrease of Xe concentration during the WI and WO sequences. After induction of bronchoconstriction, local ventilation defects could be visually detected. Animals showed a reduced Xe concentration in affected areas (1.27±0.68 mg/mL) compared to a normal state (1.91±0.65 mg/mL), and also higher concentration in non-affected areas (2.26±0.71 mg/mL) compared to a normal state.
Conclusion: This animal study suggests that Xe-DECT can be used to acquire spatial and dynamic data of lung ventilation as well as to detect hypoventilated regions due to bronchoconstriction.
Limitations: Only six animals were used in this study.
Ethics committee approval: Animal board approval was obtained.
Funding: Work supported by UZ Brussel department of Radiology.

Non-contrast-enhanced 3D-UTE MRI for pulmonary imaging of immunocompromised patients during haematopoietic stem cell transplantation

C. Metz[1], D. Böckle[1], J. F. Heidenreich[1], A. Weng[1], T. Benkert[2], G. U. Grigoleit[1], T. A. Bley[1], H. Köstler[1], S. Veldhoen[1]; [1]*Würzburg/DE,* [2]*Erlangen/DE (metz_c1@ukw.de)*

Purpose: To evaluate the feasibility of non-contrast-enhanced 3D-UTE MRI for pulmonary imaging in immunocompromised patients during haematopoietic stem cell transplantation (HSCT).
Methods and materials: 28 patients with an indication for allogeneic HSCT were included in this prospective single-centre study and underwent thoracic MRI before HSCT initiation, in case of suspected pneumonia, and before discharge following completion of HSCT. MRI was acquired using a prototypical stack-of-spirals 3D-UTE sequence within a single breath-hold. Clinically indicated MDCT and a clinically used T2 weighted sequence were used as diagnostic reference. 3D-UTE MR and T2 weighted MR image sets were separately reviewed by two radiologists regarding presence of pleural effusions (PE), ground-glass opacities (GGO), and consolidations. Each MDCT used as reference for MRI results was assessed regarding the same items in consensus reading.
Results: A total of 62 MRI scans were acquired without periprocedural complications. 3D-UTE MRI allowed for sufficient imaging of pulmonary consolidations (sensitivity 78%, specificity 82%, PPV 84%, and NPV 76%). Regarding PE (sensitivity 54%, specificity 99%, PPV 92%, and NPV 89%) and GGO (sensitivity 49%, specificity 87%, PPV 45%, and NPV 88%), the diagnostic performance was lower. Overall consistency rate was high (79-90%). Inter-rater agreement was moderate to substantial (PE=0.62, GGO=0.57, consolidations=0.70). 3D-UTE was equivalent (54%) or superior (43%) when compared to T2 weighted MRI in detecting ground-glass opacity areas and consolidations.
Conclusion: With an acquisition time similar to MDCT, radiation-free and contrast-free 3D-UTE MRI can be expected to play a major role in future pulmonary imaging, for example, in diagnostics and follow-up of immunocompromised patients with pneumonia.

Automated lung segmentation in chest radiographs using convolutional neural networks trained by means of a database augmented with a generative adversarial neural network

R. López-González[1], M. Roca-Sogorb[2], F. Garcia-Castro[2], A. Alberich-Bayarri[2]; [1]*Alzira/ES,* [2]*Valencia/ES (lopgon.rafael@gmail.com)*

Purpose: Automated lung segmentation in chest x-rays can bring many benefits for the optimisation of image analysis pipelines, such as lung textures quantification and pathologies classification. Our goal was to improve lung segmentation by using convolutional neural networks (CNN) and a database augmented by means of a generative adversarial neural network (GAN).
Methods and materials: Three public datasets of chest radiographs with manual segmentation masks of the lungs were gathered for the purpose of training CNNs. To increase the variability of the dataset, the radiographs from healthy subjects were augmented by means of a GAN. Additionally, 100 manually segmented cases from the ChestXray14 database were used for testing purposes.
To evaluate different deep learning approaches, a deeply-supervised UNET and a Mask R-CNN were trained with the augmented samples. The performance of both models was measured by means of the Dice score coefficient between the predictions and the manual segmentations of the ChestXray14 database.
Results: The model based on the deeply-supervised UNET architecture obtained an average Dice score of 0.94 for the right lung and 0.95 for the left lung. The model based on the Mask R-CNN architecture obtained an average Dice score of 0.96 for the right lung and 0.96 for the left lung.
Conclusion: Optimising the segmentation of the lungs in chest radiographs is feasible by means of convolutional neural networks trained with augmented data. The use of these techniques allows the learning of robust segmentation models and refining them with the generation of realistic augmented data.
Limitations: The main limitation of the study was that the models were evaluated in a test set of 100 images. A larger test database should be collected.
Ethics committee approval: n/a

Visualisation of combined dark-field and attenuation chest x-rays from patients

R. C. Schick[1], W. Noichl[1], T. Urban[1], M. Frank[1], K. Willer[1], J. Mohr[2], T. Köhler[3], J. Herzen[1], F. Pfeiffer[1]; [1]*Garching/DE,* [2]*Karlsruhe/DE,* [3]*Hamburg/DE (rafael.schick@tum.de)*

Purpose: Using a clinical prototype for x-ray dark-field chest radiography, attenuation, differential-phase, and dark-field radiographs of the human chest are obtained to investigate the diagnostic value for chronic obstructive pulmonary disease and emphysema. Therefore, different visualisation concepts of combined dark-field and attenuation images are evaluated.
Methods and materials: In the hue-saturation-visibility colour space, the two images are fused together by entering different channels of the colour space: the dark-field signal determines the hue and saturation channel while the transmission value determines the value channel. In the red-green-blue-alpha colour space, the combination is achieved by a superposition of the two images using the transparent alpha-channel. For this purpose, the dark-field signal strength is encoded by a colour map while also defining a transparency map. The colour map is subsequently superimposed on the attenuation image using the transparency map.
Results: For each patient, an individually adjustable overlay is available to the radiologists as an additional tool to identify and evaluate possible diagnostic findings as well as to assess the strength of the signal of different lung regions.
Conclusion: The combined visualisation of both the attenuation and dark-field chest radiographs allows the correlation of the strength of the dark-field signal, i.e. the amount of intact alveolar structures with the accurate spatial position in the thorax accessible in the attenuation image, and thus provides a valuable tool to further investigate the clinical benefit of dark-field imaging.
Limitations: Perfectly registered images as obtained by the prototype for x-ray dark-field chest radiography are required.
Ethics committee approval: The study was approved by the ethics committee and by the national radiation protection agency. Participants gave written informed consent.
Funding: Partially funded by Philips Medical Systems DMC GmbH, Hamburg, Germany.

X-ray dark-field chest radiography: optimal noise filtering for best image quality

Y. N. Leonhardt[1], J. H. W. Bodden[1], K. Willer[2], M. Frank[2], A. A. Fingerle[1], T. Koehler[3], D. Pfeiffer[1], E. J. Rummeny[1], F. Pfeiffer[1]; [1]*Munich/DE,* [2]*Garching/DE,* [3]*Hamburg/DE*

Purpose: To demonstrate an optimal noise reduction technique and optimal level of noise reduction in x-ray dark-field radiography of the human chest.
Methods and materials: X-ray dark-field radiographs of the chest were taken of lung-healthy human subjects and patients at different stages of chronic obstructive pulmonary disease (COPD) (58 patients; 64.6 ± 12.2 years; 31% female) with a grating-based prototype dark-field scanner with a field of view similar to conventional chest radiographs (37 x 37 cm²), and the acceleration voltage set to 70 kVp. The level of noise allowed in the reconstruction was defined as σ. During the reconstruction algorithm, different levels of noise reduction were applied ($\sigma_{min} = 10^{-5}$; $\sigma_{max} = 7.0$) and the raw image, as well as the reconstructed images, were assessed by two experienced radiologists in terms of image definition and noise independently.

Results: A noise level of σ = 1 was unanimously perceived to lead to the optimal image quality in in-vivo dark-field chest x-ray radiographs.
Conclusion: Moderate noise reduction in in-vivo dark-field chest x-ray radiographs may lead to an improvement in image quality in contrast to the raw image, while a high amount of noise reduction may lead to a loss of anatomical information. Thereby, noise reduction may increase usability in a clinical setting as well as in future investigations with regard to the evaluation of diseases, e. g. improved diagnosis and staging of COPD.
Limitations: n/a
Ethics committee approval: This ongoing prospective study was institutional review board (IRB) approved and the dark-field contrast x-ray imaging device has been approved for use in humans by the Federal Office for Radiation Protection.

X-ray dark-field chest radiography: reconstruction of image signals from a scanning moiré system used in a first patient study

W. Noichl[1], F. de Marco[1], K. Willer[1], T. Urban[1], M. Frank[1], R. C. Schick[1], T. Koehler[2], J. Herzen[1], F. Pfeiffer[1]; [1]*Garching/DE,* [2]*Hamburg/DE*

Purpose: To develop a robust approach for the image reconstruction within the scopeof a first clinical patient experiment on x-ray dark-field chest radiography investigating its potential benefits for the diagnosis of pulmonary disorders.
Methods and materials: Images were acquired using an x-ray grating interferometer tailored to clinical dark-field imaging of the human chest, operating at 70kVp. Three gratings were placed in the x-ray beam path, the first and second generating an intensity pattern, which was then analysed, utilising the third one. Conventionally, this is done by acquiring images at different relative positions of the gratings. Since constraints given by the fabrication process and alignment difficulties prevent the use of full-field gratings, the interferometer was moved continuously to obtain the necessary field of view of 37×37cm^2. Consequently, moving the gratings with respect to each other needed to be avoided to keep acquisition times sufficiently short (7s). Instead, by a slight misalignment of the gratings, a so-called moiré fringe pattern was formed. The contrast of these fringes was reduced by small-angle scattering within the tissue, which constitutes the dark-field signal and could be extracted by combining several of these displaced fringe patterns.
Results: An attenuation image, comparable to a conventional radiograph, and a dark-field image were computed from the overlapping raw detector images obtained from the scanning system.
Conclusion: Dark-field images can be obtained from a scanning setup meeting clinical requirements concerning coverage and acquisition speed.
Limitations: Due to the scanning acquisition scheme, there are some well-localised residual fringe artifacts caused by cardiac motion.
Ethics committee approval: The study was approved by the national radiation protection agency and the institutional review board.
Funding: Partially funded by Philips Medical Systems DMC GmbH, Hamburg, Germany.

X-ray Darkfield Chest Radiography: Evaluation of Diagnostic Image Quality in Inspiration and Expiration

C. Müller-Leisse[1], T. Urban[2], R. C. Schick[2], G. Zimmermann[1], T. Koehler[3], D. Pfeiffer[1], A. A. Fingerle[1], E. J. Rummeny[1], F. Pfeiffer[1]; [1]*Munich/DE,* [2]*Garching/DE,* [3]*Hamburg/DE (tina.ml@web.de)*

Purpose: To evaluate the first dark-field chest x-ray images on living humans and to assess image quality and visual impression, comparing inspiration and expiration.
Methods and materials: We have recently designed, constructed, and commissioned a worldwide first experimental prototype for grating-based dark-field chest radiography. 54 patients with either an overall inconspicuous chest CT or signs of pulmonary emphysema were selected and underwent conventional chest x-ray in inspiration as well as dark-field imaging in expiration and inspiration, posterior-anterior respectively.
All images were evaluated by two blinded radiologists analysing the images in terms of quality and signal strength, comparing those in expiration and inspiration. Clinical information (history of lung emphysema yes/no) was later taken into account.
Results: We found that both images in inspiration and expiration using x-ray dark-field radiography show good quality and appear to be feasible for clinical use.
Looking at one of the dark-field images only was enough to identify pulmonary diseases such as pulmonary emphysema, although having both dark-field radiographs in inspiration and expiration helped to confirm the diagnosis and gave additional information to understand dynamic changes during breathing.
Conclusion: The first dark-field x-ray images on living humans show promising results with high potential clinical value in inspiration as well as expiration. To detect pulmonary diseases such as pulmonary emphysema, it is enough to have either one inspiratory or expiratory image, however, having both gave additional information about dynamic pulmonalry changes during breathing.
Limitations: In this rather early state, we only have a limited number of examinations to analyse. We expect more concrete and significant results during the course of our study.
Ethics committee approval: An approval by the institutional review board (IRB) was obtained.

X-ray dark-field chest radiography: discussion of image signal dependencies of patients biometric data

F. Meurer[1], M. Frank[2], W. Noichl[2], G. Zimmermann[1], T. Koehler[3], A. A. Fingerle[1], D. Pfeiffer[1], E. J. Rummeny[1], F. Pfeiffer[2]; [1]*Munich/DE,* [2]*Garching/DE,* [3]*Hamburg/DE*

Purpose: To discuss the dependence or independence of x-ray dark-field radiography signal intensity and biometric data of healthy lungs.
Methods and materials: A grating-based dark-field chest x-ray prototype has been constructed and approved by the federal office for radiation protection to enable chest x-ray radiography of the human lung. Lung scans of 54 patients were included in this evaluation. Three from each other independent radiologists, trained in assessment of dark-field images, rated the overall dark-field signal intensity with a five-point ordinal scale. Furthermore, a quantitative evaluation of the signal intensity was performed. Statistical tests were made to find differences between different ages, various body mass indices, and the sex of the study participants.
Results: Present preliminary results indicate that there is no strong difference in objective and especially subjective evaluation of the dark-field signal intensity for different genders or various body mass indices. Only the participant's age shows a slight but significant negative correlation with signal intensity in objective evaluation. In a subjective rating, there was no difference.
Conclusion: The present preliminary results indicate that the dark-field signal intensity of the healthy lung is not correlated with gender and body weight. Just age and signal intensity correlate slightly negatively with each other in objective analysis. This is important because it indicates that any changes in the signal levels are more likely to be caused by lung diseases rather than biometric differences in patients.
Limitations: n/a
Ethics committee approval: This patient study has been approved by the institutional review board (IRB).

RPS 1704-12 09:36
X-ray dark-field chest radiography: comparison of 70 kVp grating-based attenuation chest x-ray image quality with conventional chest x-rays
M. Renz[1], M. Kattau[2], T. Urban[2], G. Zimmermann[1], T. Köhler[3], D. Pfeiffer[1], A. A. Fingerle[1], E. J. Rummeny[1], F. Pfeiffer[1]; [1]Munich/DE, [2]Garching/DE, [3]Hamburg/DE (martin.renz@tum.de)

Purpose: To compare attenuation chest x-rays acquired with a grating-based prototype dark-field chest x-ray system to conventionally acquired chest x-rays regarding image quality and diagnostic confidence.
Methods and materials: A grating-based prototype system capable of acquiring dark-field and attenuation chest x-rays at 70 kVp was constructed. Due to limited grating size, it employs a slot-scanning image acquisition procedure with an acquisition time of 7 seconds. In our clinical study, 79 patients have been included so far. With every examination using our grating-based dark-field system, the attenuation signal is obtained simultaneously with the dark-field signal. As a reference, conventional chest x-rays are included for every patient using a standard clinical x-ray system operating at 125 kVp. On both systems examinations in p.-a. and lateral view are conducted. Visual comparison of grating-based and conventional chest x-ray was quantified by three independent readers.
Results: The utilisation of slot-scanning in our grating-based setup, as well as lower kVp, leads to reduced scatter and therefore higher contrast compared to conventional imaging. Long local exposure of 700 ms due to scanning procedure causes minimal blurring of the aortic and mediastinal silhouette. Visually quantified image quality and diagnostic confidence ratings of attenuation chest x-rays acquired with our prototype dark-field chest x-ray system were on par with ratings of conventional clinical chest x-rays. In both imaging variants, pulmonary parenchyma, as well as vascular, bronchial and osseous structures, are well differentiated.
Conclusion: Simultaneously acquired attenuation chest x-rays obtained by our prototype dark-field chest x-ray system are similar to conventional chest x-ray imaging regarding the diagnostic value.
Limitations: n/a

X-ray dark-field chest radiography: correlation of results from the first COPD-patient study to CT-based COPD analysis
A. Sauter[1], M. Kattau[2], K. Willer[2], G. Zimmermann[1], A. A. Fingerle[1], T. Koehler[3], D. Pfeiffer[1], E. J. Rummeny[1], F. Pfeiffer[2]; [1]Munich/DE, [2]Garching/DE, [3]Hamburg/DE (andreas.sauter@tum.de)

Purpose: To compare living human emphysema quantification using the first x-ray dark-field chest radiograph examinations versus CT.
Methods and materials: In total, 500 patients will be included in this study. So far, 79 patients were recruited after receiving a clinical CT-scan with contrast showing no pulmonary pathologies besides emphysema. For each patient, four dark-field images of the thorax (posterior-anterior and lateral, in inspiration, and in expiration) were performed using a clinical prototype. All images were evaluated by three radiologists who were blinded to the GOLD-stadium regarding signal strength. Based on the rating for signal strength, grading of emphysema was performed. The CT-examination of each patient was evaluated with dedicated software (IntelliSpace Portal, Philips GmbH) regarding the percentage of emphysematous lung tissue. Consequently, the correlation between visual dark-field signal and resulting grading of emphysema and CT based emphysema quantification was evaluated.
Results: The results from this first clinical dark-field chest radiography demonstrate a high correlation of CT and dark-field images regarding the grading of pulmonary emphysema. Dark-field images obtained in inspiration showed a better correlation with CT compared to dark-field images obtained in expiration. Posterior-anterior images showed a better correlation than lateral images, but the latter are useful for anatomical assignment.
Conclusion: Detection and grading of COPD is possible with dark-field x-ray radiography with a high correlation to CT, resulting in decreased radiation exposure (0.04 mSv) as well as fewer time expanses.
Limitations: Only a relatively small number of patients was included. For further evaluation, more patients have to be examined.
Ethics committee approval: The study was institutional review board (IRB) approved. All patients signed informed consent.
Funding: Partially funded by Philips Medical Systems DMC GmbH, Hamburg, Germany.

X-ray dark-field chest radiography: a correlation of first results from COPD-patients with lung function tests
A. A. Fingerle, K. Willer, W. Noichl, A. Sauter, G. Zimmermann, T. Köhler, D. Pfeiffer, E. J. Rummeny, F. Pfeiffer; Munich/DE (alexander.fingerle@tum.de)

Purpose: To investigate dark-field chest x-ray for the detection and staging of chronic obstructive pulmonary disease (COPD) by correlation of dark-field signal strength to lung function tests in a first patient study.
Methods and materials: In this ongoing prospective clinical study, 79 of 500 adult study participants (250 patients with different stages of COPD and 250 patients without lung diseases) were enrolled. Dark-field chest x-rays were acquired using a grating-based prototype imaging setup operating at 70 kVp in scanning mode. As a reference, conventional chest x-ray, whole-body plethysmography, and COPD assessment test were performed. Clinically indicated computed tomography scans were also included in the study. Visual assessment of dark-field signal strength using a 5-point ordinal scale was performed by three independent readers. In addition, dark-field signal strength was quantitatively evaluated. Results were correlated with findings of lung function tests.
Results: Dark-field signal strength correlated with the Tiffeneau-Pinelli index, which is given as the ratio of forced expiratory volume in 1 second (FEV1) to forced vital capacity (FVC), and FEV1 as a percent of predicted measured in whole-body plethysmography.
Conclusion: Dark-field signal strength may serve as a diagnostic marker of pulmonary function in COPD by visualising structural changes of the lung parenchyma. As a novel imaging modality, dark-field chest x-ray may have the potential to facilitate early diagnosis of COPD and improve the monitoring of the clinical course of disease while requiring less cooperation than spirometry.
Limitations: n/a

Dark-field chest radiography: influence of the breathing state on image appearance
T. Urban[1], K. Willer[1], W. Noichl[1], M. Frank[1], R. C. Schick[1], J. Mohr[2], T. Koehler[3], J. Herzen[1], F. Pfeiffer[1]; [1]Garching/DE, [2]Karlsruhe/DE, [3]Hamburg/DE (theresa.urban@tum.de)

Purpose: To evaluate the first clinical dark-field chest x-ray images with respect to the breathing state of the patient.
Methods and materials: We constructed a clinical prototype for dark-field chest radiography suitable for human chest imaging, with an overall acquisition time of 7 seconds and a tube voltage of 70kVp. So far, more than 80 patients have been examined in posterior-anterior orientation in inspiration and expiration, with an average effective dose of 0.04mSv per radiograph.
Results: The dark-field signal in the lung can vary in strength due to both a difference in lung thickness as well as microstructural variations. In inspiration, the dark-field signal is quite homogeneous over the lung, which can be attributed to a homogeneous distribution of alveolar size and density. In expiration, the dark-field signal is higher, particularly in the lower parts of the lung. This is likely caused by an increase of air-tissue interfaces in the beam path due to the compression of lung parenchyma. The difference in dark-field signal between the two breathing states allows spatially identification of the regions of the lung that change micro-morphologically and thus participate in the ventilation of the lung.
Conclusion: This technique provides spatial information about microstructural changes in the lung and thus the physiological activity of different lung regions during breathing. The change in signal strength illustrates its sensitivity to the microstructure of the lung, promising a distinct diagnostic value of dark-field images for the assessment of lung diseases.
Limitations: At this rather early state of the ongoing study, there is a limited number of examinations.
Ethics committee approval: The study was approved by the ethics committee and by the national radiation protection agency. Participants gave written informed consent.

A ten-year survey of different treatment approaches to tendinopathy of the supraspinatus tendon: PRP (platelet-rich plasma) or physical therapy?
G. Campidoglio[1], F. Bruno[2], S. Mariani[2], F. Arrigoni[2], L. Zugaro[2], A. Barile[2], C. Masciocchi[2]; [1]Rome/IT, [2]L'Aquila/IT (giuseppe.campidoglio@gmail.com)

Purpose: To evaluate clinical and morphological results of PRP treatment in patients with chronic tendinopathy of the supraspinatus tendon with a 10-year follow-up.
Methods and materials: We retrospectively evaluated, through clinical and MR examination, all patients selected for intratendinous PRP injections for the treatment of the supraspinatus degeneration between 2008 and 2018. The instrumental follow-up included MRI scans performed before and at the time of the follow-up. The patients were also evaluated with both clinical and functional examinations, namely the VAS and constant score.
Results: A total of 86 patients were treated and 57 were included in the analysis with pre and post-treatment examinations. 60 patients matched for age, sex, and disease duration were enrolled as a control group. Among all patients treated, 8 underwent surgical repair and 7 conservative therapy, 3 showed a low VAS score and bad clinical outcome, and 4 only a low VAS. Overall, 26 patients presented with VAS <4, whereas 20 with VAS=0. Among the control group, 8 patients underwent surgical repair and 18 alternative therapies. 4 patients showed a low VAS score and bad clinical outcome and 4 only a low VAS.
Conclusion: Our experience suggests that intratendinous injection of PRP did not modify the long-term natural history of tendinopathy. Nevertheless, it showed a significant impact on the VAS score and constant score.
Limitations: The small sample size of analysis.

3D isotropic MR-arthrography in the abduction-external rotation position to evaluate on-track/off-track lesions in anterior shoulder instability
F. Formiconi, M. Ruschioni, C. Gianneramo, F. Bruno, F. Arrigoni, S. Mariani, L. Zugaro, A. Barile, C. Masciocchi; L'Aquila/IT (formiconifrancesco@gmail.com)

Purpose: To evaluate the ability of shoulder three-dimensional (3D) magnetic resonance arthrography (MRA) and additional ABER (abduction-external rotation) scans to assess bipolar bone loss and detect on-track/off-track lesions in traumatic shoulder instability, by using MPR CT images as reference.
Methods and materials: 25 consecutive patients (14 male, 11 female, range 20-44) with clinical evidence of anterior shoulder instability. All patients underwent 3D-CT of the shoulder and direct shoulder MRA using three-dimensional (3D) isotropic PD sequences in standard and ABER position. Two blinded independent observers randomly evaluated the images twice to assess the glenoid track, the Hill-Sachs interval, and to predict engagement by using the "on-track/off-track" method. The intra and interobserver agreement was calculated.
Results: Out of 25 defect combinations, 13 were codified as non-engaging and 12 as engaging by using the "on-track/off-track" method. The intraobserver reliability was 0.921 for 3D-CT and 0.786 for MRA. The interobserver agreement ranged from "substantial" to "almost perfect" for both glenoid track and Hill-Sachs interval measurements ($p<0.005$). ABER MRA predicted engagement accurately in 23 cases (91.3%).
Conclusion: MRA using 3D isotropic PD sequences is a reliable method in assessing defects of bone in patients affected by anterior shoulder instability and bipolar bone loss by using the "on-track/off-track" method. The same sequence in the ABER position could predict the presence of engaging lesions.
Limitations: The small sample size.

CT evaluation of different outcomes after variations of Bristow-Latarjet operations in a 1-year follow-up
Y. Zhao, H. Yuan; Beijing/CN (stormare_7@sina.com)

Purpose: The Bristow-Latarjet operation (coracoid translocation), which has developed different variations, is an effective treatment of shoulder recurrent dislocation. Our research is to investigate the merit and demerit of these variations by analysing CT images in a 1-year follow-up.

Methods and materials: 200 patients with shoulder recurrent dislocation who had a Bristow-Latarjet operation in our hospital were involved. They were divided into 6 groups. 25 cases were bone block fixed with anchor (G1), 52 cases inlay with single screw (G2), 15 cases no-inlay with single screw (G3), 67 cases inlay with single pair of buttons (G4), 14 cases with double screws (G5), and 27 cases with double pairs of buttons (G6). The size of bone block and un-union were evaluated in CT on the postoperative day, and at 3, 6, and 12 months.
Results: The increase of step below articular surface compared to postoperative day: G2>G4 in 3 months ($p<0.05$); G6>G1, G2, and G4 while G2>G4 in 6 months ($p<0.05$); G6>G1, G2, G3, and G4 in 12 months ($p<0.05$). The decrease of bone length along the tunnel: G1, G4, and G6>G2 while G6>G3, G4, and G5 in 6 months ($p<0.05$); G1, G4, and G6>G2 while G6>G3 in 12 months ($p<0.05$). The un-union rates in 3 months were 70% (significantly high), 2.73% (significantly low), 50%, 17.2%, 45.5%, and 30.4%, but were not significantly different in other stages.
Conclusion: Bone block absorption perpendicular to the articular was more after fixed with a single screw rather than buttons inlay and with double pairs of buttons rather than single fixation and anchor. Bone block absorption along the tunnel was more after fixed with buttons than a screw and with a single pair of buttons than double. Bone block un-union happened more in the early stage after fixed with anchor and less after fixed with a single screw inlay.
Limitations: A limited number of cases in some groups.

Visualisation of the coracoglenoid ligament in shoulder MR on 3DPD images and the evaluation of its association with shoulder pathologies

S. Rajan, R. S. Rajan, N. S. Batta, H. Mahajan, V. Mahajan, M. Murugavel, V. K. Venugopal*; New Delhi/IN (drsriramrajan@gmail.com)*

Purpose: To assess the visualisation of the coracoglenoid ligament (CGL) on PD CUBE images in 100 consecutive MR shoulder and to assess the association of absent visualisation of this ligament with pathologies of the shoulder.
Methods and materials: 100 consecutive MR shoulders were anonymised and retrospectively reviewed by three subspecialty musculoskeletal radiologists with 16 years, 15 years, and 12 years' experience on PD 3D CUBE images by triangulation on sagittal and axial images. The ligament was scored as 1-3 scale (not seen, indeterminate, and well seen). Posterosuperior labral tears, long head biceps tendon pathology, tear of the supraspinatus and subscapularis tendons, biceps pulley lesions, rotator interval ligaments, and synovial thickening in the rotator interval were also scored on a 1-3 scale (not seen, indeterminate, and well seen). Appropriate statistical tests were performed.
Results: The CGL was well seen on 82% cases by R1, in 78% by R2, and 70% by R3. The CGL was defined as absent in 13% cases by R1, 18% by R2, and 8% by R3 (with additional cases marked as wispy/thin CGL). Cases where CGL was not seen due to rotator interval synovial thickening was marked 5% by R1, 4% by R2, and 22% by R3. Amongst the cases with absent CGL, 69% had associated SLAP tear and 38% had associated long head of biceps tendon pathology. The rest of the pathologies did not have a significant association with CGL absence.
Conclusion: We demonstrate a consistent visualisation of the coraco-glenoid ligament on plain 3D PD images and an association of the absence of this ligament with SLAP tear and lesser degree of association with long head of biceps tendon pathology.
Limitations: The absence of surgical correlation.

T2 mapping at 3T MRI detects glenoid labral matrix changes in patients with and without superior labral anterior to posterior (SLAP) lesions of the shoulder using arthroscopy as a reference

C. Rehnitz, F. Wuennemann*; Heidelberg/DE (felix.wuennemann@med.uni-heidelberg.de)*

Purpose: Using arthroscopy as a gold standard, we prospectively evaluated T2 mapping of the shoulder regarding matrix changes of the labrum in patients with and without superior-labral-anterior-to-posterior (SLAP) lesions.
Methods and materials: T2 mapping was performed at 3T in 18 consecutive patients (12 men) with shoulder pain followed by shoulder arthroscopy. Two independent raters performed a region-of-interest-analysis in the superior labrum using the colour-coded T2 map. Inter-rater correlation coefficients (ICCs) were calculated. Cut-off values and their sensitivities/specificities including 95% confidence intervals (CI) for detection of SLAP lesions were assessed using arthroscopy as reference. $P<0.05$ was considered significant.
Results: The mean age did not differ significantly between n=12 patients with SLAP lesions and n=6 patients without SLAP lesions (55.5 vs 46.2 years, p=0.22). The mean T2 value in labra with proven SLAP lesions was significantly higher compared to those with no SLAP lesions (mean, 37.7±10.6 ms vs 20.8±2.4 ms, p=0.0001). A complete data separation was present, as the maximum T2 value (21.2) in labra with no SLAP lesion was lower than the minimum value in labra with lesions (27.8). Therefore cut-off values between 21.2 and 27.8 ms resulted in a sensitivity of 100% (95%CI:[73.5%-100.0%]) and specificity of 100% (95%CI:[54.1%-100.0%]). ICC was 0.97 and 95%CI:[0.9-0.99].
Conclusion: Higher T2 values in labra containing SLAP lesions indicate a higher degree of damage to the collagen network within the matrix. T2 mapping may be used as an additional tool to evaluate the biochemical labral matrix changes at the shoulder.
Limitations: The small sample size.
Ethics committee approval: Written informed consent. Approved by ethics committee of the University of Heidelberg.

Ultrasound evaluation of subdeltoid fluid collection and supraspinatus tendon thickness after surgical repair of the supraspinatus tendon and correlation with clinical results

H. J. Park, D. Y. Ahn*; Seoul/KR (cat3305@nate.com)*

Purpose: To investigate whether the repaired tendon thickness and sub-deltoid fluid collection after rotator cuff repair, which was seen on follow-up ultrasound (US), are correlated with clinical outcome and to assess whether these factors lead to different clinical outcomes depending on the surgical method.
Methods and materials: This retrospective study included 54 patients who underwent supraspinatus tendon repair with a suture-bridge or single-row technique and follow up US. Two radiologists independently measured the thickness of the repaired supraspinatus tendons and fluid collection in sub-deltoid space. We assessed the relationship between the sonographic parameters, including repaired supraspinatus tendon thickness and sub-deltoid fluid collection, with the clinical outcome represented by the Korean shoulder scoring system (KSS) score using correlation coefficients (R).
Results: There was a significant relationship between sub-deltoid fluid collection and the pain of the patients ($p\leq0.05$), although every category showed an inverse relationship with the fluid thickness. The ICC values for sonographic imaging parameters between interpreters ranged from 0.910 to 0.946, showing excellent reproducibility.
Conclusion: Sub-deltoid fluid collection of repaired supraspinatus tendons measured on postoperative US can be a useful method in predicting the patient's subjective clinical outcome, especially pain, regardless of age or surgical technique.
Limitations: This was a retrospective study. The measurement of sonographic parameters was based on captured images that had been taken prior to assessment and therefore it was not a real-time measurement.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Semi-dynamic MRI of the extensor digitorum tendons in Jaccoud arthropathy

T. P.-E. Kirchgesner, M. Stoenoiu, N. Michoux, X. Libouton, F. Houssiau, B. Vande Berg; *Brussels/BE (thomas.kirchgesner@uclouvain.be)*

Purpose: To test the hypothesis that Jaccoud arthropathy (JA) in systemic lupus erythematosus (SLE) patients is associated with abnormal extensor digitorum (ED) tendons displacement during flexion of the metacarpophalangeal (MCP) joints.
Methods and materials: 16 SLE patients with JA (JA+), 12 SLE patients without JA (JA-), and 24 control subjects were included in the study. Transverse spin-echo T1-weighted MR sequences of the MCP joints in flexion and in extension were obtained in each hand of SLE patients and in one randomly-selected hand of control subjects. Two radiologists separately measured the amplitude and the direction of the displacement of the ED tendons with respect to the midline at the level of the MCP joints. Statistical analysis included two-way ANOVA with random effects to assess differences in amplitude ($p<0.0083$), Fisher-Freeman-Halton's exact test to assess differences in direction ($p<0.0063$), and Gwet's AC1 score to determine interobserver agreement.
Results: The amplitude of the displacement of the ED tendons was statistically significantly higher in JA+ patients than JA- patients and controls in flexion for both readers ($p<0.0001$) and in extension for one reader ($p<0.0048$). Ulnar deviation of the ED tendons was statistically significantly more frequent in JA+ patients than in JA- patients and controls in flexion and in extension for both readers ($p<0.0001$).
Conclusion: JA is associated with the abnormal displacement of the ED tendons in flexion and extension. Abnormal displacement of the ED tendons is absent in patients without JA.
Limitations: In the absence of anatomical correlation, we are unable to precisely determine the anatomic lesions associated with the instability of the ED tendons.
Ethics committee approval: This study was approved by our institutional ethics committee. All study participants provided written informed consent.
Funding: No funding was received for this work.

Assessment of cartilage disorders after distal radius fracture using biochemical and morphological non-enhanced magnetic resonance imaging

V. Mori, C. Schleich, D. B. Abrar, M. Frenken, G. Antoch, L. Oezel, S. Gehrmann, L. Wollschläger; *Düsseldorf/DE (valentina.mori@med.uni-duesseldorf.de)*

Purpose: To assess radiocarpal cartilage after distal radius fracture with intra-articular and extra-articular extension using multiparametric, non-enhanced magnetic resonance imaging (MRI).
Methods and materials: In this prospective study, multiparametric MRIs of the radiocarpal cartilage were performed in 26 participants (16 male, 10 female; mean age 39.5±14.7 years, range 20-70 years) using a 3-Tesla MRI. The cohort consisted of 14 patients with distal radial fractures and 12 healthy volunteers. The radiocarpal cartilage was assessed using morphological (DESS, TrueFISP) and biochemical (T2*) MRI sequences without the application of an intravenous contrast agent. The modified Outerbridge classification system for morphological analyses and region-of-interest biochemical analysis were applied to assess the degree of cartilage damage in each patient.
Results: Morphological cartilage assessment showed no significant difference between the DESS sequence and the reference standard, TrueFISP ($p= 0.75$). In the morphological (DESS, TrueFISP) and biochemical (T2*) assessments, patients with intra-articular fractures did not show greater cartilage damage than those with extra-articular fractures (DESS, $p=0.62$, TrueFISP, $p=0.32$, and T2*, $p=0.97$). Significantly greater cartilage degradation was observed after distal radius fracture compared to controls (DESS, $p=0.0001$, TrueFISP, $p=0.0001$, and T2*, $p=0.009$).
Conclusion: Magnetic resonance imaging using advanced, multiparametric sequences facilitates accurate, non-invasive assessment of cartilage changes after distal radius fracture without the need for a contrast agent. Post-traumatic radiocarpal cartilage damage did not differ between fractures with intra- and extra-articular extension, but patients with fractures showed significantly higher cartilage degradation compared to healthy controls.
Limitations: A small sample size. No arthroscopic or histological confirmation. Missing inter- and intra-reader reliability for biochemical imaging.
Ethics committee approval: 5087R. Approved by the local review board.

Defining the normal reference range for the cross-sectional area of the median nerve at the wrist and forearm using high-resolution ultrasonography in asymptomatic Asian adults

M. Rauf, F. Raza, R. Nazir, B. Yawar Faiz, R. Aqeel; *Islamabad/PK (mari23392@gmail.com)*

Purpose: Ultrasonography (USG) is a reliable, inexpensive, readily available, and painless modality for the diagnosis of carpal tunnel syndrome. However, the main sonographic criteria of the cross-sectional area (CSA) of the median nerve shows a wide normal variation depending on regional and ethnical differences, which warrants the establishment of the normal range of variability in the dimensions of the median nerve in the local population. In our experience, the normal average cross-sectional area of the median nerve in the asymptomatic adult Asian population is relatively small compared to other populations worldwide.
Methods and materials: 500 asymptomatic patients/1,000 median nerves were evaluated by high-resolution USG using Toshiba Aplio 500 at the distal wrist crease and mid-forearm 12 cm above the distal wrist crease by 3 expert radiologists independently over a period of 2 years (July 2017-July 2019).
Results: The median nerve CSA in our population at the right wrist was 6.8±1.9 mm^2 while at the left wrist was 6.6±1.9 mm^2. The CSA at the right forearm was 5.3 ± 1.4 mm^2 while at the left forearm was 5.2±1.5 mm^2 ($P<0.001$). Also, the CSA was relatively larger in males than females.
Conclusion: The CSA of the median nerve at the wrist and forearm in the Asian population is relatively smaller compared to other populations worldwide. This further enforces the idea to define normal reference range for CSA of the median nerve by obtaining normative data for our population.
Limitations: Only Pakistani asymptomatic adults included. Results should be correlated with other available Asian population data as well as data available worldwide for better reference range determination.
Ethics committee approval: Approved by our institutional review board.
Funding: No funding was received for this work.

RPS 1710-10 09:34

Direct visualisation of finger flexor pulley injuries at 3T and 7T MRI: an ex vivo feasibility study

R. Heiß[1], C. Lutter[2], R. Janka[1], M. Uder[1], V. Schöffl[3], F. W. Roemer[1], T. Bayer[3]; *[1]Erlangen/DE, [2]Rostock/DE, [3]Bamberg/DE (Rafael.Heiss@uk-erlangen.de)*

Purpose: To evaluate the feasibility and to compare image quality and diagnostic performance of 3T and 7T magnetic resonance imaging (MRI) protocols for the direct depiction of finger pulley ruptures using anatomic preparation as the reference.
Methods and materials: 30 fingers from 10 human cadavers were examined at 3T and 7T before and after being subjected to single and multiple iatrogenic pulley ruptures. MRI protocols were comparable in duration. Two experienced radiologists evaluated the MRIs and defined the location and morphology of finger pulley lesions. Image quality was graded according to a 4-point Likert scale. The diagnostic performance was assessed with anatomic preparation as a gold standard. Interobserver agreement was calculated using Cohen's Kappa coefficients (κ).
Results: In a comparison of 7T versus 3T sensitivity and specificity for the detection of A2, A3 and A4 pulley lesions were comparable with 100% versus 95%, respectively, 98% versus 100%. In the assessment of A3 pulley lesions sensitivity of 7T was superior to 3T MRI (100% vs 83%), whereas specificity was lower (95% vs 100%). Image quality assessed before and after iatrogenic rupture was comparable with 2.74 for 7T and 2.61 for 3T, reflecting adequate image quality in average, whereas the visualisation of the A3 finger flexor pulley

before rupture creation was significantly better for 7T ($p<0.001$). Interobserver variability was substantial at 7T ($\kappa=0.90$) and 3T ($\kappa=0.80$).
Conclusion: MRI at 3T and 7T allows direct visualisation and characterisation of traumatic A2, A3, and A4 pulley lesions with higher agreement rates for 7T. High-field MRI is a modern approach for the pre-surgical evaluation compared to indirect techniques such as ultrasound depending of bowstringing.
Limitations: An ex-vivo cadaver study.

Low-dose CT scanning of the clavicula for age estimation: loss of confidence?

S. Gassenmaier, J. F. Schäfer, K. Nikolaou, I. Tsiflikas*; Tübingen/DE (sebastian.gassenmaier@med.uni-tuebingen.de)*

Purpose: Computed tomography (CT) features are the reference standard in evaluating the ossification process of the medial clavicular epiphysis for forensic age diagnostics in adolescents and young adults. Consequently, the highest efforts on radiation reduction are warranted. Therefore, the aim of this study was to investigate the feasibility of low-dose CT of the clavicula for age estimation.
Methods and materials: 207 non-contrast chest CT of 144 patients born between 1988–2012, performed in 2018 due to various clinical indications, were included in this retrospective study. The mean patient age was 16.9±6.6 years. Patients were divided into a low-dose (LD; n=146) and high-dose (HD; n=61) group. Image quality and ossification stages (using the 5-stage classification including the subgroups 2a-3c) were assessed by two radiologists independently. Confidence levels were evaluated for subgroups 2a-3c. Radiation dose was determined via dosimetry software.
Results: A dose simulation with a z-axis reduction to depict the clavicula only resulted in a median exposure of 0.1 mSv (IQR: 0.0) in LD compared to 0.9 mSv (IQR: 0.6) in HD ($p<0.001$). The median image quality was rated significantly worse in LD compared to HD with a median of 3 (IQR: 1) versus 4 (IQR: 0) by both readers on a Likert-scale ranging from 1-4 ($p<0.001$ for both readers). There was an almost perfect agreement for the ossification stages between both readers with a Cohen's kappa of 0.83 ($p<0.001$). Median confidence levels of both readers were not significantly different between LD and HD (reader 1: $p=0.186$; reader 2: $p=0.074$).
Conclusion: Low-dose CT of the clavicula for age estimation is possible without a loss of confidence.
Limitations: No randomisation regarding scanning protocol was performed due to the retrospective character.
Ethics committee approval: IRB approval obtained. Informed consent waived.
Funding: No funding was received for this work.

Significant differences in dynamic contrast-enhanced perfusion MRI of healthy regions and histologically confirmed medication-related osteonecrosis of the jaw

F. A. Huber, S. Morgenroth, P. Schumann, N. J. Rupp, R. Guggenberger*; Zurich/CH (florian.huber@usz.ch)*

Purpose: To investigate differences in perfusion-MRI parameters between healthy and pathologic regions in patients with a histologically confirmed medication-related osteonecrosis of the jaw (MRONJ).
Methods and materials: in a retrospective analysis, standard parameters of dynamic contrast-enhanced (DCE) perfusion MRI of 22 patients, who received the examinations as part of a dedicated clinical MRI protocol for MRONJ assessment, were evaluated. Same sized regions of interest were placed into a representative bone of defined regions. All regions were assessed qualitatively by a blinded expert radiologist as ground truth (4-point Likert-scale; normal, mild-severe changes). Furthermore, histologic confirmation was present for the resected regions.
Results: The mean patient age was 75.2 years (+/- 9.9; 12 female patients). Wash-in (0.15 vs 0.05) and positive enhancement integral (PEI; 0.17 vs 0.11) values were significantly higher in MRONJ-affected regions than in healthy jaw areas ($p<0.05$ for both). Furthermore, DCE-parameters partially correlated with qualitative expert ratings (wash-in, PEI, initial area under the curve, all $p<0.05$).
Conclusion: DCE-MRI reveals significantly different bone perfusion in MRONJ-affected regions of the mandible and maxilla compared to the healthy jaw. Disease extent according to MRI data was larger than visible necrotic areas during clinical examination and may help to evaluate the severity of this adverse drug effect.
Limitations: This is a retrospective single-centre and single-scanner investigation. All perfusion data was retrieved from MRONJ-diagnosed patients. While clinical and radiological assessment did not indicate pathologic alterations in regions defined as healthy, possible subvisual alterations of the healthy jaw may represent a limitation. However, a control-cohort of healthy volunteers was not used for ethical reasons.
Ethics committee approval: Written consent by all patients and IRB approval was given.
Funding: No funding was received for this work.

The value of the frontonasal suture as a specific personal identification: evaluation on three-dimensional cinematic rendering computed tomography images

N. Pattamapaspong, S. Chumsaengsri, S. Ruengdit, C. Madla, K. Mekjaidee, S. Prasitwattanaseree, P. Mahakkanukrauh*; Chiang Mai/TH (nuttaya@gmail.com)*

Purpose: Specific personal identification (fingerprint or DNA matching) is strong evidence in forensic examinations but is mostly lost with decomposition. Sutures on skulls are commonly preserved. The morphology of frontonasal sutures varies among individuals and can be clearly demonstrated by three-dimensional CT (3DCT) images using a new rendering technique. Cinematic volume rendering is a new technique which improves the clarity of 3DCT images and can display skull sutures. We asked whether 3DCT images of the frontonasal suture created by the cinematic volume rendering technique can be used as specific personal identification.
Methods and materials: CT images of 50 dry skulls were reformatted to 3DCT images by using a cinematic volume rendering technique on a commercially available workstation (syngo.via, version VB20). Photographs of the dry skulls were adjusted by a blurring effect on Photoshop. Four readers (an anatomist, forensic anthropologist, forensic doctor, and radiologist) responded to three questionnaires, firstly matching a 3DCT image with the photographs of dry skulls, secondly determining minimum levels of clarity of the suture on dry skull photographs that they can use for matching, and thirdly determining the level of clarity which 3DCT displayed using photographs of dry skulls as a reference.
Results: Correct matching rates were high for all readers (98-100%). The mean values of visual grading analysis scores for clarity of the sutures on 3DCT (63-77%) are higher than that of the minimum level that each reader required for matching (37-50%) ($p<0.001$, $p=0.0039$).
Conclusion: 3DCT images of the frontonasal suture created by cinematic volume rending can be used for personal identification. If a clinical CT of the skull of a missing person is available, 3DCT images can be later reformatted and used as pre-mortem data.

Selective axillary dissection after neoadjuvant chemotherapy in patients with lymph node positive breast cancer (CLYP study): interim report of a prospective study

C. M. L. Trombadori, R. Rella, M. Conti, E. Bufi, M. Romani, L. Zagaria, G. Franceschini, P. Belli, R. Manfredi*; Rome/IT*
(charlotte.trombadori@gmail.com)

Purpose: To evaluate the accuracy of image-guided localisation and removal of lymph nodes containing known metastases in breast cancer patients treated with neoadjuvant chemotherapy (NACT).
Methods and materials: 64 patients with breast cancer and nodal metastases who underwent NACT between 2017 and 2019 were prospectively enrolled. A clip was placed in the sampled node. After NACT, patients underwent sentinel lymph node (SLN) dissection, removal of the clipped node (CN), and subsequent axillary lymphadenectomy (ALND). Pathological results of SLN and CN were compared to ALND to assess the false-negative rate (FNR).
Results: Axillary pathological complete response at ALND was 43,8%. FNR of SLN was 25%, with 9 false-negative (FN) events in 36 patients with residual disease. In 6/9 patients with FN SLNs, the CN contained metastases, resulting in an FNR of 8.3%. Basing on the number of abnormal nodes on initial staging, in patients with 1-3 abnormal nodes (21 patients) residual disease was identified in 10 patients at ALND (47,6%). The SLN didn't reveal metastases in 4/10 patients (FNR=40%) while the CN didn't reveal metastases in 1 patient (FNR=10%). In >4 abnormal nodes (43 patients), the FNRs of SLN and CN were 19,2% and 7,7%, respectively. According to radiological response to NACT, in patients with complete radiological response (cRR) (38 patients), the FNR of SLND was 35.3% (6 FN events in 17 patients with residual disease). In 4/6 patients with FN SLNs, the CN contained metastases, with an FNR of 11,7%. In patients without cRR (26 patients), the FNRs of SLN and CN were 15.8% and 5.3%, respectively.
Conclusion: CN could improve accuracy of axillary staging in node-positive patients who received NACT, especially in N1-stage and in patients with cRR.
Limitations: Nodal-stage on initial staging.
Ethics committee approval: The study was approved by an ethics committee.

Evaluation of longer duration use of wire-free SCOUT 31-516 days prior to surgery of breast and axillary lesions in neoadjuvant chemotherapy patients: a pilot study

M. K. Hayes, H. Wright, E. Bloomquist*; Hollywood, FL/US*
(hayesmac@comcast.net)

Purpose: To assess the long-term performance of wire-free SCOUT localisation in the breast and axilla in neoadjuvant chemotherapy patients prior to surgery.
Methods and materials: Adult female breast cancer patients had wire-free SCOUT localisation (WFL) prior to neoadjuvant treatment and surgery between February 13, 2017, and July 3, 2019. Electronic medical record and surgical pathology determined the study endpoints.
Primary: Rate of successful surgery using WFL prior to NACT.
Secondary: Number of days to surgery, success rate of WFL placement, stability, and device-related complications.
Results: 38 WFL (16 breast and 22 axilla) were successfully placed prior to NACT in 34 patients, age 29-74 (mean 52) years. All (100%) underwent definitive breast cancer surgery after 32 to 516 (average 198) days. Standard imaging (MG, US, MRI, CT) was used to monitor response to NACT, specimen radiograph and surgical pathology reports documented no significant SCOUT migration (>5mm), no adverse events, and no obscuration of target tissue in 16/16 MRI exams.
Conclusion: Since longer-duration SCOUT WFL lead to successful surgery without adverse events or limitations on MRI, this study suggests the possibility of a clinically relevant paradigm shift regarding the timing of preoperative localisation. WFL prior to NACT response maintains flexible options for the surgical team, including de-escalation of breast or axillary lymph node surgery.
Limitations: This single-institution pilot was limited by a small study size. A multi-centre study including other WFL devices (TAG, MAGSEED, SmartClip) may provide further generalised knowledge for breast treatment teams.
Ethics committee approval: This prospective pilot study was approved by the institutional review board and written informed consent was obtained.
Funding: No funding was received for this work.

MRI prediction of response to neoadjuvant chemotherapy in breast cancer: a comparison between patients with and without tumoral calcifications on mammography

T. Sella, B. Simor, B. Maly, E. Carmon*; Jerusalem/IL*
(tamarse@hadassah.org.il)

Purpose: MRI is documented as the most accurate imaging modality to evaluate response to neoadjuvant chemotherapy (NAC). consequently, surgical planning is mandated by post-NAC MRI findings. However, if the tumour demonstrates extensive calcification on mammography (MG) at diagnosis, complete excision of calcifications is the common practice, regardless of MR findings. The purpose of this study was to examine the ability of MRI to predict complete response in tumours with versus without calcifications on MG.
Methods and materials: We retrospectively analysed pre and post NAC MG and MRI in 114 consecutive patients at a single institution, 64 (56%) with non-calcified tumours and 50 (44%) with calcifications on MG which correlated in extent with the suspicious enhancement on MRI. Response to NAC was assessed on MRI and compared with post-surgical pathology. Statistical analysis was performed using Chi-square or Fisher exact test, $p< 0.05$ considered significant.
Results: Demographics and tumour characteristics were similar in both groups. MRI predicted response to NAC equally in both groups showing 40% vs 41% complete, 52% vs 53% partial, and 8% vs 6% no response in patients with calcifications compared to no calcifications respectively (p=0.958). Concordance between MRI prediction and response on pathology was equal between the 2 groups, 70% with calcifications and 69% without, p=0.886. Among discordant cases, there was a small non-significant tendency for overestimation of response by MRI in patients without calcifications (19% vs 12%, p=0.24). Mastectomy was more commonly performed in patients with calcifications (66%) than those without (52%).
Conclusion: MRI predicts response to NAC equally in patients with calcified versus non-calcified tumours. Post NAC surgical planning based on MR findings should be considered in patients with tumour calcifications similar to those without.
Limitations: A retrospective study.
Ethics committee approval: Informed consent was waived.
Funding: No funding was received for this work.

DWI-based response evaluation after neoadjuvant systemic treatment of breast cancer: comparison with RECIST-based criteria

R. Ota[1], M. Kataoka[1], M. Iima[1], M. Honda[2], S. Kanao[1], T. Kataoka[1], M. Toi[1], K. Togashi[1]*; [1]Kyoto/JP, [2]Osaka/JP (ota_rie0624@kuhp.kyoto-u.ac.jp)*

Purpose: To evaluate treatment response based on diffusion-weighted imaging (DWI) after neoadjuvant systemic treatment (NST). DWI score based on signal patterns on DWI were compared to RECIST-based evaluation.
Methods and materials: Breast cancer patients who underwent dynamic contrast-enhanced (DCE) MRI and received NST followed by surgery between 2014 and 2019 (n=116) were analysed.
MRI protocols were as follows: T1WI, T2WI, DWI (TR/TE=7000/62 ms; b=0, 1000 sec/mm2), and DCE-MRI performed on 3.0 Tesla scanner (Siemens AG, Erlangen, Germany) with 18 or 16 channel dedicated breast coils. The MRIs were retrospectively evaluated by two radiologists with 20 and 3 years experience of breast MRI, and the target lesions were given a 3-point score .

The RECIST-based evaluation was further classified into 3 groups (PD, SD, PR/near CR/CR).
Pathological evaluation: pCR was defined as no residual invasive or non-invasive cancer in breast tissue on histopathology from surgical resection (in situ lesion was allowed). Statistical analysis was performed with MedCalc. The diagnostic performance of DWI parameters in discriminating pCR was assessed using a receiver operating characteristic (ROC) analysis. For RECIST-based criteria, they were grouped as pCR or non-pCR.
Results: Among 116 cases, 40.5% (47/116) achieved pCR while 59.5% (69/116) were categorised as non-pCR on pathology. The DWI score was strongly associated with residual disease. ROC analysis showed area under the ROC (AUC) of 0.96 (95% confidence interval: 0.91-0.99). ROC analysis of RECIST-based evaluation showed AUC of 0.70 (95% Confidence interval: 0.60-0.78).
Conclusion: DWI-based evaluation of residual disease is a useful approach of breast cancer following NST.
Limitations: Visual assessment.
Ethics committee approval: This study protocol was approved by our institutional review board.
Funding: No funding was received for this work.

Muscle mass loss after neoadjuvant chemotherapy in breast cancer: estimation on breast magnetic resonance imaging using pectoralis muscle area
F. Rossi, L. Torri, S. de Giorgis, M. Calabrese, A. Tagliafico*; Genoa/IT*

Purpose: Sarcopenia is widely considered a predictor of poor survival and toxicity in breast cancer patients. The aim of this study was to evaluate if there is pectoralis muscle area (PMA) variation, reflecting a loss of skeletal muscle mass, on consecutive MRI examinations during neoadjuvant chemotherapy.
Methods and materials: A total of n=110 consecutive patients (mean age 56±11years) who were treated with NAC for histologically proven primary breast cancer between January 2017 and January 2019, and in whom tumour response was checked with standard breast MRI, were included. Two radiologists calculated the pectoralis muscle cross-sectional area before and after NAC.
Results: The time between the two MRI examinations, before starting NAC, and after completion of three cycles of NAC was 154,8±34 days. PMA calculated pre-NAC (8,14 cm^2) was larger than PMA calculated post-NAC (7,03 cm^2), ($p<0.001$). According to RECIST criteria, there were no significant differences between responders (complete or partial response) and no responders ($p=0.362$). The multivariate regression analysis did not show any significant relationships between ΔPMA and age, the time between MRI exams, estrogen and progesterone receptor status, human epidermal growth factor receptor status (HER-2), Ki-67 expression, lymph nodes status, RECIST criteria, or histological type and grade. Inter-reader ($k=0.72$) and intra-reader agreement (0.69 and 0.71) in PMA assessment were good.
Conclusion: Pectoralis muscle mass variation, reflecting loss of skeletal muscle mass, in breast cancer patients undergoing NAC can be estimated directly on standard breast MRI.
Limitations: Known limitations are the retrospective nature of the study and the lack of a control-group.
Ethics committee approval: The study was approved by our institutional review board. Written informed consent was obtained.
Funding: No funding was received for this work.

The value of different tumour regression of MRI in evaluating the efficacy of neoadjuvant chemotherapy for breast cancer
X. Mei, J. Ma, X. Lin, C. Yi*; [2]Shenzhen/CN*
(2635063963@qq.com)

Purpose: To analyse the different shrinkage pattern of breast tumors in magnetic resonance imaging (MRI) after neoadjuvant chemotherapy (NAC) and to evaluate the efficacy of different shrinkage pattern in chemotherapy.
Methods and materials: Data from 50 patients who were diagnosed with unilateral breast cancer underwent NAC before surgery after the eighth cycle of NAC was analysed retrospectively. All patients underwent MRI scan with contrast enhancement. The shrinkage pattern was classified into 3 categories: concentric shrinkage, fragment-like shrinkage, and mixed shrinkage. All the patients were divided into pathological complete response (pCR) group and N-pCR group according to the histopathologic tumour response. The χ^2 test were used to compare the baseline characteristics of pCR and N-pCR groups, as well as the tumour enhancement pattern and shrinkage pattern of the molecular types. Associations were evaluated using binary logistic regression models.
Results: 16 patients achieved pCR and 34 patients had a residual disease (N-pCR). Age, menopausal status, tumour size, lymph node, T stage, molecular typing, ER, PR, ki-67 status, and tumour enhancement mode on MRI showed no significance between pCR and N-pCR groups (all $p>0.05$), while only HER2 status and shrinkage pattern a significant difference ($p<0.05$ in both). Interobserver agreement regarding shrinkage pattern was moderate after NAC (Kappa value 0.719). There were no statistically significant differences in tumour shrinkage pattern and MRI tumour enhancement among the molecular types (all $p>0.05$). There were statistically significant differences in MRI tumour enhancement in the tumour shrinkage pattern ($p<0.05$). Logistic model showed that tumour shrinkage pattern after NAC and HER2 status were independent factors for predicting pCR.
Conclusion: Shrinkage pattern and HER2 status can be independent factors for predicting pCR.
Limitations: A retrospective study.
Ethics committee approval: LL-KT-201801162.

The combined use of ADC with DCE-MRI in early assessing of response to neoadjuvant chemotherapy in patients with breast invasive ductal carcinomas
L. Liu, W. Peng, B. Yin, Y. J. Gu*; Shanghai/CN*
(llbbsy@163.com)

Purpose: To combine the dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and ADC value to serve as early response markers in breast cancer after NAC.
Methods and materials: Between July 2014 and July 2016, 50 patients who received NAC were considered to be eligible. All patients underwent a pretreatment breast routine ultrasonography, MRI, DCE-MRI, and DWI. 50 patients underwent these examinations four times prior to treatment. 1st, 2nd, and following the final cycle of NAC. Responses were measured by routine MRI and ultrasonography using the response evaluation criteria in solid tumours (RECIST).
Results: The areas under the ROC curve were 0.627 for the ultrasonography in early assessment of the response to NAC. The areas under the ROC curve were 0.735 for routine MRI in early assessment of the response to NAC. There was a significant difference between responders and nonresponders in K^{trans}, Kep, and TTP after the first cycle of therapy （$P=0.022<0.05$). Among various perfusion parameters, the largest areas under the ROC curve were 0.84 for Kep, then that of K^{trans}(0.75). In a combined examination, the largest areas under the ROC curve was 0.88 and that of combined ADC and K^{trans} was the second (0.84).
Conclusion: Kep and K^{trans} are superior to routine MRI and ADC value in the early assessment of the response to NAC. Combined ADC with Kep and ADC with K^{trans} are the most recommended parameters that may help determine individual treatments.
Limitations: The number of cases was small. All cas-es were invasive ductal carcinoma. This might affect the evalua-tion results.
Ethics committee approval: Information about review or animal board approval and written informed consent.
Funding: No funding was received for this work.

Impact of pathologic complete response definition on MRI diagnostic performance after neoadjuvant systemic therapy
D. A. Hashem, M. T. El-Diasty, A. Khazindar, A. Abusanad, S. Bakhsh, A. Bin Mahfuoz*; Jeddah/SA (Dalia-hashim@hotmail.com)*

Purpose: Determining disease extent after neoadjuvant chemotherapy (NAC) is essential for accurate surgical planning. Achieving pathologic complete response (pCR) has shown to have favourable prognosis in certain tumour subtypes, however, the definition of pCR varies between authors and can affect the interpretation of results at systematic reviews. We aimed to investigate the diagnostic accuracy of post-NAC MRI with reference to different pCR definitions.
Methods and materials: Records of patients with locally advanced breast cancer who underwent NAC followed by mastectomy between January 2016 and January 2019 were retrospectively reviewed. Post-treatment MRI was correlated with residual disease on final histopathology. Two definitions for pCR were used; the first was an absence of both invasive and in situ components, and the second was an absence of invasive component only. Diagnostic accuracy of post treatment MRI was tested against both definitions separately.
Results: 52 women (mean age, 47.4 years; range 28-74) with 56 breast masses were eligible for the study. Complete MRI response was noted in 22 (39%) masses. pCR was achieved in 14 (25%) and 25 (44.6%) masses using the first and second pCR definitions respectively. Negative predictive value (NPV) and overall accuracy of MRI for detecting residual disease was 50% and 75%, respectively, using the first pCR definition. With the second pCR definition, NPV and accuracy were 77.3% and 76.8%, respectively.
Conclusion: MRI NPV for residual disease was higher with the second pCR definition, however, overall accuracy was not different. MRI accuracy in detecting residual disease after NAC is not adequate to replace pathological assessment.
Limitations: Retrospective design, small sample size, and at single institution.
Ethics committee approval: This retrospective study was approved by the institutional review board with waiving of the informed consent.
Funding: No funding was recieved for this work.

Early prediction of axillary lymph node metastasis and their response to neoadjuvant systemic therapy with ^{18}F-FDG PET/CT in breast cancer patients
C. M. de Mooij, C. Mitea, F. Mottaghy, M. B. I. Lobbes, M. Smidt, T. van Nijnatten*; Maastricht/NL (c.demooij@maastrichtuniversity.nl)*

Purpose: To assess the value of ^{18}F-FDG PET/CT in predicting the presence of axillary lymph node metastasis (ALNM) and their response to neoadjuvant systemic therapy (NST) in breast cancer patients.
Methods and materials: We analysed 37 patients with breast cancer that underwent ^{18}F-FDG PET/CT prior to NST. Maximum standardised uptake values of the primary tumour (SUV-T) and the most FDG-avid lymph node (SUV-LN) and their ratio (NT ratio) were calculated. Patients with and without suspicious ALNM based on prior imaging were compared regarding their SUV values. ALNM response following NST was classified according to the Pinder classification. Patients were defined as responders (Pinder 1-3) and non-responders (Pinder 4). The association of SUV_{max} with ALNM response was assessed using ROC analyses.
Results: Of 37 patients, 25 (68%) had suspicion for ALNM. Patients with suspected ALNM showed significantly higher SUV-LN (1.5 vs. 6.1) and NT ratio (0.3 vs. 1.0), but no significant difference in SUV-T (6.0 vs. 8.3) was found. Non-significant differences between responders and non-responders of SUV-T (7.5 vs. 8.2), SUV-LN (5.6 vs. 5.1), and NT ratio (0.9 vs. 0.7) were found. The AUCs for SUV-T, SUV-LN, and NT ratio were 0.544, 0.630, and 6.11, respectively. An SUV-LN cutoff value of 3.5 had a sensitivity of 75% and a specificity of 49% in identifying patients who responded to NST.
Conclusion: ^{18}F-FDG PET/CT showed promising results in predicting ALNM and their response to NST in breast cancer patients.
Limitations: These results are preliminary, hence the low sample size.
Ethics committee approval: The need for informed consent was waived by a local ethics committee.
Funding: No funding was received for this work.

MRI response evaluation after neoadjuvant chemotherapy: what are the factors of radiologic-pathologic discordance?
S. Mevlütoğlu[1], Ö. Aslan[1], I. G. Bilgen[1], A. O. Oktay Alfatli[1], L. Yeniay[1], O. Zekioğlu[2]*; [1]İzmir/TR, [2]Bornova-İzmir/TR (sevdamevlutoglu@hotmail.com)*

Purpose: To assess which clinicopathologic and radiologic factors influence magnetic resonance imaging (MRI) performance in the demonstration of radiologic response (false positive/negative results) in breast cancer after neoadjuvant chemotherapy (NAC).
Methods and materials: A total of 80 patients with breast cancer who underwent breast MRI before and after NAC was included in this study. All patients were diagnosed with core-needle biopsy before treatment for histological tumour type and immunohistochemical markers. Pathological examination was referenced as a gold standard after complete surgical excision. Complete radiological response (rCR) to NAC was accepted when the main lesion site showed no early enhancement on dynamic MRI.
Complete pathologic response (pCR) was described as the complete absence of invasive cancer in the surgical material.
The clinicopathologic and radiologic factors which influence the radiologic-pathologic correlation were analysed.
Results: The mean age of cohort was 43.5 years (range:24-64).
MRI analysis after NAC showed rCR in 44 cases (55%), while pathological analysis of surgical specimens after NAC detected pCR in 43 cases (53.8%).
Based on MRI findings, the radiologic-pathologic discordance was in 23 of 80 cases. Multivariate analysis of radiologic findings to identify predictors: dense breast parenchyme (BIRADS type C-D), multifocal multicentric lesions, high parenchyme enhancement, and non-mass enhancement in post-treatment MR imaging. Also, there were significantly more frequent cases of tumour nuclear histologic grade luminal B subtype.
Conclusion: Patients with dense breast parenchyme (BIRADS type C-D), high parenchyme enhancement, multifocal multicentric lesions, luminal B, invasive ductal type cancer, and non-mass enhancement in post-treatment MR imaging are significantly associated with radiologic-pathologic discordance on MR imaging after NAC. These patient populations should be evaluated in depth.
Limitations: A retrospective study, limitation in the number of patients.
Ethics committee approval: n/a

Assessment of the usefulness of monitoring tumour volume and stiffness in evaluating neoadjuvant chemotherapy treatment responses in breast cancer
K. S. Dobruch-Sobczak, H. Piotrzkowska-Wróblewska, Z. Klimoda, J. Litniewski*; Warsaw/PL*

Purpose: To determine whether a classifier based on two US parameters (volume and stiffness) is predictive of treatment responses from the first courses of neoadjuvant chemotherapy (NAC).
Methods and materials: Prospective US analysis was performed in patients with breast cancer qualified for NAC, before and 7 days after the first four courses of NAC. US examinations with strain sonoelastography were performed using linear transducer L14-5. Tumour volume and tumour stiffness (using Tsukuba scale) were evaluated. The resistant malignant cells [RMC] (ranging from 0–100%) were assessed by a pathologist postoperatively. Histopathological examination classifies tumours as responding (RT) and non-responding (N-RT). RT included those with a reduction in cellularity ≥30% while

N-RT was <30%. Correlation analysis, univariate, and multivariate logistic regression analysis were used for statistical assessment.
Results: A total of 42 breast cancer in 30 patients (mean age 56.4y) were examined. A statistically significant correlation was found between stiffness, volume, and RMC ($p<0.05$) after 2, 3, and 4 courses of NAC. In logistic regression, the best results were after the 3rd course of NAC. Using only stiffness as a prognostic parameter, we obtained a sensitivity of 37%, specificity of 87%, PPV 70%, NPV 63%, and for volumes respectively: 47%, 77%, 74%, and 67%. The classifier using both parameters showed a sensitivity of 73%, specificity 75%, PPV 68%, and NPV 78%.
Conclusion: The use of two US parameters, volume and stiffness, are highly predictive of tumour response after the 3rd NAC cycle and performed better than single parameters.
Limitations: A small group.
Ethics committee approval: The study was approved by the institutional bioethical review board of each participating institution.

Breast MRI affects overall survival but not disease-free survival in breast cancer patients: a retrospective population-based study

T. van Nijnatten[1], L. van Tiel[2], A. C. Voogd[1], K. Groothuis-Oudshoorn[2], S. Siesling[3], M. B. I. Lobbes[4]; [1]*Maastricht/NL,* [2]*Twente/NL,* [3]*Utrecht/NL,* [4]*Sittard-Geleen/NL (Thiemo.nijnatten@mumc.nl)*

Purpose: To evaluate the effect of breast MRI on overall survival (OS) and disease-free survival (DFS) of patients with invasive breast cancer in the Netherlands.
Methods and materials: We selected all women from the nationwide cancer registry diagnosed with invasive breast cancer (a) between 2011-2013 for the OS-cohort and (b) in the first quarter of 2012 for the DFS-cohort. The study population was divided into a MRI and non-MRI group. In addition, subgroups were created according to breast cancer subtype: invasive carcinoma of no special type (NST) versus invasive lobular carcinoma (ILC). OS and DFS were compared between the MRI and non-MRI group using the Kaplan-Meier method and the log-rank test. Cox proportional hazard regression analysis was performed to estimate hazard ratio (HR) with a 95% confidence interval (CI). To account for missing data, multiple imputation was performed.
Results: Of the 31,756 patients included in the OS-cohort (70% non-MRI and 30% MRI), 27,752 (87%) were diagnosed with invasive carcinoma NST and 4,004 (13%) with ILC. Multivariable Cox regression showed that breast MRI had a tendency towards better OS (HR 0.91, 95%-CI 0.74-1.11) and was statistically significant for patients aged >50 years (overall). Of the 2,464 patients included in the DFS-cohort (72% non-MRI and 28% MRI), 2,161 (88%) were diagnosed with invasive carcinoma NST and 303 (12%) with ILC. Multivariable Cox regression analysis showed that breast MRI was not significantly associated with DFS (HR 1.16, 95%-CI 0.81-1.67).
Conclusion: Breast MRI was not significantly associated with an improved DFS and revealed a tendency towards an improved OS, which was only significant for patients aged >50.
Limitations: Retrospective and observational design.

The accuracy of a MRI scan for the prediction of pathological response (pCR) in neoadjuvant chemotherapy (NACT)

E. Giannotti, P. M. Moseley, T. Abdel-Fatah, J. Walker, K. D. Jethwa, S. Chan; *Nottingham/UK (ytteb84@hotmail.com)*

Purpose: To investigate the accuracy of MRI in evaluating response to neoadjuvant chemotherapy (NAC) in primary breast cancer and to determine if the presence of DCIS/LCIS can influence the accuracy.
MRI has a high specificity for the correct detection of residual tumour after NAC, but low sensitivity (correct identification of complete pathological response (pCR) PPV 48% has been reported).
Methods and materials: A cohort of 461 consecutive patients who received NAC in a single cancer centre (2007–2019) with post-NAC pre-surgery MRI and surgery pathology data were analysed. 'Gold Standard' for the response was pCR in the surgical specimen. Radiological complete response (rCR) was defined as 0 mm and non-rCR defined as ≥1 mm, using maximum tumour diameter on MRI.
Results: In the whole cohort, MRI sensitivity (probability of identifying a pCR from rCR)=71.0% (88/124), and specificity (probability of correctly identifying non-pCR from non-rCR)=81.0% (273/337).
The presence of DCIS/LCIS in the surgical sample reduces the accuracy of MRI assessment, sensitivity by 24.8% (with=53.1% vs without=77.9%), and specificity by 2.4% (with=78.6% vs without=81.0%), increasing overestimation of disease size. False-negative rate (probability of rCR incorrectly identifying pCR) is 46.9% with DCIS/LCIS versus 22.1% without DCIS/LCIS.
Conclusion: This analysis showed that there is a need to improve the accuracy of MRI assessment of pCR.
There is an urgent need to identify variables which can improve this invaluable tool to optimise treatment planning.
Introducing a volumetric and texture AI-driven analysis may increase the accuracy and confidence of MRI with positive clinical benefit leading to better patient treatment and less invasive approach to surgery.
Limitations: A retrospective study. Further researches needed.

Bone marrow signal intensity on breast MRI in women with breast cancer

I. Bokov[1], P. M. Sklair Levy[2], D. M. Ben-David[2], D. O. Haisraely[2]; [1]*Rehovot/IL,* [2]*Ramat Gan/IL (inna5566@gmail.com)*

Purpose: Women with breast cancer receiving neoadjuvant chemotherapy undergo breast MRI as part of treatment response assessment. Incidental sternal bone marrow enhancement may be demonstrated and be confused with pathologic findings. Our goal was to evaluate bone marrow enhancement on MRI prior to and upon completion of neoadjuvant treatment.
Methods and materials: A retrospective study between the years 2012-2017 included 109 consecutive women with breast cancer and treated with neoadjuvant chemotherapy. MRI was performed before and after treatment to evaluate response. The neoadjuvant regimen included AC-T in adjunct with G-CSF (bone marrow stimulating agent) and steroids. Bone marrow signal intensity was measured at the sternum, before and after contrast injection. Chest wall muscle signal intensity was used as a reference. The index was calculated as bone marrow signal intensity divided by muscle signal intensity prior, upon completion, and 1 year after completion of neoadjuvant treatment. MRI was performed on average 80 days from the end of treatment. Statistical correlation between bone marrow index, age, disease stage, and time from the end of treatment.
Results: The mean patient age was 50 and 98% were diagnosed with invasive ductal carcinoma. Bone marrow index prior to neoadjuvant treatment was 1.9, upon completion of treatment 3.5, and 1.4 at 1 year follow up. Age was found to be inversely correlated to bone marrow index, the bone marrow index was found to be significantly higher in women younger than 48y. No statistical correlation was found between the time of MRI from the end of treatment and disease stage.
Conclusion: MRI bone marrow signal intensity may be high in women with breast cancer upon completion of NAT. It may be secondary to treatment with GCSF. This should not be confused with pathological enhancement suspicious of metastatic disease.

Which MRI morphologic criteria can better predict the response after neoadjuvant chemotherapy (NAC) in axillary lymph nodes (ALN)?

V. Ruggeri, M. Durando, G. Mariscotti, E. Regini, G. Bartoli, I. Castellano, P. Fonio*; Turin/IT (vruggerim@gmail.com)*

Purpose: To investigate which MRI morphologic criteria can predict residual disease in ALNs in patients who have undergone NAC.
Methods and materials: From 2017 to 2019, 60 consecutive patients with advanced breast cancer who underwent 1,5 T MRI before and after NAC were retrospectively collected. Pre- and post-NAC MRI were retrospectively analysed by two dedicated radiologists in consensus, blinded to histological results, evaluating both quantitative (number and diameter) and qualitative criteria (irregular margins, absence of fatty hilum, cortical thickness>3mm, perifocal oedema, rim enhancement, and asymmetry comparing with contralateral side) related to ALNs. ALNs status was evaluated by sentinel ALN biopsy or axillary dissection and nodal pathological response classified according to Pinder's criteria [complete response (pCR) versus no-complete response (no-pCR)]. Statistical analysis (Chi-square or Fisher's exact tests for categorical variables, non-parametric Mann-Whitney test for continuous variables) was performed to compare pCR versus no-pCR cases.
Results: At baseline MRI, no-pCR cases ALNs were characterised by loss of fatty hilum (93.3% versus 44.4% in pCR, p=0.02), presence of rim enhancement (86.7% versus 11.1% in pCR, p=0.001), asymmetry (93.3% versus 44,4% in pCR, p=0.02), average cortical thickness significantly larger (9.5 versus 3.7 mm, p=0.004) than pCR cases. At post-NAC MRI, average cortical thickness was significantly (p=0.01) larger in no-pCR patients compared to pCR (4.5 versus 1.8 mm). Considering as suspicious ALN with at least one of the above characteristics, MRI sensitivity, specificity, positive and negative predictive values, and accuracy for assessing ALNs response were 88.2%, 77.8%%, 88.2%, 77.8%, and 84.6%, respectively.
Conclusion: Based on our results, supporting the use of MRI in assessing nodal response after NAC, abnormal ALNs cortical thickness seems to be the most reliable parameter associated to no-pCR.
Limitations: Small sample, monocentric study.
Ethics committee approval: n/a

Right ventricular myocarditis: the great imitator of cardiac magnetic resonance. A retrospective hystologically-based comparison with ARVC

F. Cilia, N. Galea, L. Marchitelli, G. Cundari, G. Mancuso, G. Pambianchi, I. Carbone, C. Catalano, M. Francone*; Rome/IT (fcilia91@hotmail.it)*

Purpose: Isolated right ventricular involvement in myocarditis (RV-myo) is an uncommon event, sharing overlapped clinical and morphological manifestations with arrhythmogenic right ventricular cardiomyopathy (ARVC), consisting of regional wall motion abnormalities, RV enlargement, impaired ejection fraction (EF), and late gadolinium enhancement (LGE). The two conditions have shown to be misdiagnosed with CMR in approximately 50% of cases.
Methods and materials: From a database of 12 consecutive patients undergoing endomyocardial biopsy (EMB) with an initial CMR suspicion of ARVC, we retrospectively identified 8 cases with a histological diagnosis of ARVC and 4 with RV-myo. Biventricular volumes, CMR tissue abnormalities, and clinical data were systematically compared and matched with current CMR diagnostic criteria of ARVC.
Results: 2 ARVC patients presented with a long-standing history of syncope, whereas 1 RV-myo patient presented with acute chest pain. In the remaining 9 cases, clinical presentations were highly overlapped, consisting of ECG abnormalities, variably associated with palpitations, and no troponin raise. CMR data showed comparably enlarged RV-EDV between ARVC and RV-myo (EDV/BSA respectively 117,3±32,4mL/m^2 vs.124,9±46mL/m^2,p>0.05) and reduced ejection fraction (EF:40,3±14,6% vs. 33,8±15,3%,p>0.05). RV-LGE was noted in 7/12 cases (n=3 ARVC; n=4 RV-myo), predominately involving RV free wall. Homogeneous intraventricular thickening was also observed in 2/4 RV-myo patients associated with coexisting tissue oedema. According to current CMR diagnostic criteria, the diagnosis of ARVC was established in 6/8 patients with ARVC and 2/4 with RV-myo.
Conclusion: Our results confirmed highly overlapped morpho-functional and tissue abnormalities in both pathological entities, introducing a relevant interpretation bias recalling the need for invasive characterisation in selected cases.
Limitations: A very limited study population.
Ethics committee approval: IRB and written informed consent was obtained.
Funding: No funding was received for this work.

RPS 1803-2 10:36

Non-contrast enhanced diagnosis of acute myocarditis based on the 17-segment heart model using 2D-feature tracking magnetic resonance imaging

M. Salehi Ravesh[1], M. Eden[1], P. Langguth[1], T.-C. Piesch[1], J. K. Lehmann[1], A. Lebenatus[1], D. Hautemann[2], O. Jansen[1], M. Both[1]*; [1]Kiel/DE, [2]Leiden/NL (Mona.SalehiRavesh@uksh.de)*

Purpose: To investigate the diagnostic value of myocardial deformation analysis based on the 17-segment heart model using non-contrast enhanced (CE) 2D tissue feature tracking (2D-FT) technique.
Methods and materials: 70 patients with suspected myocarditis underwent a cardiovascular magnetic resonance (CMR) examination at 1.5 Tesla. A contrast-agent-free part of this CMR protocol was additionally performed in 40 healthy volunteers (HV). Besides standard CMR data sets, 2D-FT derived segmental and global longitudinal, radial, and circumferential deformation parameters were analysed. The 2D-FT results were compared to the combined findings from CMR imaging and endomyocardial biopsy (EMB).
Results: Patients were assigned to 3 groups depending on their ejection fraction (EF) (<40%, 40-55%, and ≥55%). Compared to HV, impaired EF (<55%) was significantly correlated to reduced segmental and global strain and strain rate values. The circumferential deformation analysis was more sensitive to myocardial changes than longitudinal and radial analysis. The segmental strain/strain rate had an accuracy of 84.3%/70.0% for the diagnosis of acute myocarditis, stated by EMB and CMR in 42 of 70 patients. In patients with preserved EF, acute myocarditis could be ruled out using only segmental strain analysis with a negative predictive value of 87.5%.
Conclusion: In patients with suspected myocarditis, the deformation analysis based on the 17-segment heart model provides valuable information about functional myocardial inhomogeneity. This quantitative approach could be used in addition to the clinical standard CMR protocol and represents a promising tool in the framework of a prospective automatised multiparametric CMR imaging analysis.
Limitations: The cut-off values in this work were determined according to the results in our HV.
Ethics committee approval: No. D 407/18.

Tissue characterisation by parametric mapping and strain cardiac magnetic resonance for the detection and monitoring of myocardial injury in fulminant myocarditis

H. Li, H. Zhu, L. Xia*; Wuhan/CN (haojie8393@163.com)*

Purpose: To investigate whether multiparametric cardiac magnetic resonance (CMR) could detect and monitor inflammation myocardial alterations in fulminant myocarditis.
Methods and materials: 19 patients (35 ± 14 years, 37% male) with a clinical diagnosis of fulminant myocarditis underwent CMR examinations at 3.0T in the acute phase and at 3-months follow-up. The control group consisted of 19 healthy volunteers. The CMR protocol included cine, black blood T2-weighted imaging, T1 mapping, T2 mapping, and late gadolinium enhancement (LGE). Cardiac strain was evaluated by feature tracking.
Results: The left ventricular mass index (64 [57, 76] versus 52 [47, 63], P<0.05) and interventricular septum thickness (10.5 [9, 11.3] versus 8.3 [6.6, 9.8], P<0.001) in the acute stage was significantly higher compared with controls and normalised at the chronic stage. All quantitative inflammation metrics, including oedema ratio, LGE mass, native T1, T2, and extracellular volume were significantly (all P<0.001) decreased in the follow-up scan, but still higher than controls. Compared with the controls, strain indices were all significantly (all P<0.001) impaired in the acute stage. Native T1 and T2 values led to excellent diagnostic accuracy for discriminating fulminant myocarditis from healed myocarditis, with AUC of 0.947 and 0.931.
Conclusion: Multiparametric CMR could detect and monitor inflammation myocardial injuries in patients with fulminant myocarditis. Native T1 and T2 values achieved excellent diagnostic performance in distinguishing acute from healed myocarditis.
Limitations: Though the diagnosis of FM was made by strict clinical criteria and typical CMR findings, the lack of EMB makes the myocardial histopathological verification unavailable.
Ethics committee approval: The study was approved by our Institutional Review Board and written informed consent was obtained prior to CMR.
Funding: National Natural Science Foundation of China (No. 81873889).

RPS 1803-4 10:48

Mapping cardiac magnetic resonance (CMR) for early prediction of unfavourable left ventricle remodelling in acute myocarditis: a MIAMI study

A. Palmisano[1], G. Benedetti[2], M. Gatti[3], R. Faletti[3], N. Galea[4], M. Francone[4], A. Del Maschio[1], F. de Cobelli[1], A. Esposito[1]*; [1]Milan/IT, [2]London/UK, [3]Turin/IT, [4]Rome/IT (palmisano.anna@hsr.it)*

Purpose: A pixel-wise mapping technique resulted in more sensitive than conventional CMR images in the diagnosis of acute myocarditis. The role in the detection of subtle inflammation is still under investigation and imaging predictors of outcomes are still largely unknown.
Methods and materials: 68 patients with clinical suspicions of myocarditis underwent cardiac MR (CMR) at a 1.5T scanner for the evaluation of morpho-functionality, hyperaemia with ce-SSFP images, oedema with STIR and T2 mapping, scarred myocardium with LGE, native-T1, and ECV. When clinically indicated endomyocardial biopsy (EMB) was performed, a second CMR was performed 2 months after baseline. 45 healthy volunteers underwent CMR as the control group.
Results: Acute myocarditis was confirmed in 45 patients by both CMR and EMB. An Infarct-like presentation was the most frequent (25 patients, 56%). At baseline CMR, LV-EDV was 135 ml with EF.53%, LL criteria were positive (T2-ratio: 2.8, Hyperemia: 13%, LGE: 6%), and T1, T2 mapping, and ECV were significantly higher than normal values without difference among clinical presentation (p>0.05). Mapping parameters showed excellent diagnostic accuracy in the acute (AUC: 95%, 98%, and 90% for T1 map, T2 map, and ECV) and convalescent phases (90%, 85%, and 89% for T1 map, T2 map, and ECV). At short-term follow-up, a slight recovery of EF was experimented on with a reduction of all LL and mapping parameters. The modification of native-T1 values correlated to the recovery of EDV (R=0.8242, p=0.0005) and ejection fraction (R= -0.4559, p=0.0378).
Conclusion: Lower recovery of T1 value in the convalescent phase is associated with higher EDV and lower EF.
Limitations: A imited sample size and relatively short follow-up.
Ethics committee approval: The study was approved by Institutional Review Board. Aall study participants signed informed consent.
Funding: The study was granted by the Italian Ministry of Health.

Agreement between old and new Lake Louise criteria for the diagnosis of acute myocarditis with a different clinical onset

G. Cundari, G. de Rubeis, A. Ascione, S. Coco, F. Catapano, F. Cilia, N. Galea, C. Catalano, M. Francone*; Rome/IT (cundarigiulia@gmail.com)*

Purpose: To compare the diagnostic performance of old and new Lake Louise criteria (oLLC and nLLC) in suspected acute myocarditis patients among various clinical presentations: infarct-like [IL], cardiomyopathic [CM], and arrhythmic [A].
Methods and materials: 110 patients with a clinical suspicion of acute myocarditis underwent 1.5T cardiac magnetic resonance. The protocol included cine–SSFP, T2wSTIR, early and late gadolinium-enhancement, T2-mapping, and native and post-Gd T1-mapping. 3 patients were excluded for unknown clinical hystory. Cohen's k test was used to assess the level of agreement and a McNemar test to compare the diagnostic proportion between oLLC and nLLC among different clinical presentations.
Results: The frequency of clinical presentations were 56/107 (52%) IL, 29/107 (27%) CM, and 22/107 (20.5%) A. A diagnosis was performed in 45/110 (40.9%) patients with oLLC and in 69/110 (62.7%) with nLLC [k=0,48[0,33-0,62], p<0.01. A statistically significant difference in the agreement of oLLC and nLLC was found for CM and A presentations [15/29(51,7%) vs 7/29(24,1%), k= 0,46[0,19-0,73] p<0.01 and 11/22(50%) vs 4/22(18,2%), k=0,36[0,063-0,66], p<0.05, respectively]. No statistical difference was found for IL onset [nLLC 41/56(73,2%) vs oLLC 33/56(58,9%), k=0,45[0,22-0,69], p>0.05]. Mapping sequences allowed for the diagnosis of acute myocarditis when oLCC were negative in 5/56 (9%) for IL, 3/29 (10%) for CM, and 4/22 (18%) for A. In particular, with T1-mapping and ECV, T1 criterion was met in 9/56 (16%) IL, 7/29 (24%) CM, and 8/22 (36%) A onset (p>0.05), and, with T2-mapping, T2 criterion in 13/56 (23%) IL, 9/29 (31%) CM, and 8/22 (36%) A onset (p>0.05).
Conclusion: The degree of agreement between oLLC and nLLC was moderate for overall, IL, and CM presentations, and fair for A. nLLC allowed for a diagnosis of more acute myocardites than oLLC in CM and A onsets.
Limitations: Bioptic diagnosis of acute myocarditis was made only in few patients.
Ethics committee approval: Informed consent was obtained.
Funding: No funding was received for this work.

Early T1 shortening (eT1sh): a new CMR parameter to detect myocardial hyperemia in acute myocarditis

A. Palmisano[1], G. Benedetti[2], R. Faletti[3], M. Gatti[3], N. Galea[4], M. Francone[4], F. de Cobelli[1], A. Del Maschio[1], A. Esposito[1]*; [1]Milan/IT, [2]London/UK, [3]Turin/IT, [4]Rome/IT (palmisano.anna@hsr.it)*

Purpose: To evaluate T1-mapping based approaches for the quantification of hyperemia in patients with acute myocarditis.
Methods and materials: 55 subjects (40 patients with acute myocarditis [AM]; 15 age- and sex-matched healthy control subjects [HC]) underwent 1.5T CMR. T1 mapping was acquired before (native T1) and 2 minutes after gadoliunium administration (early-enhanced T1). 3 different T1 mapping-based parameters were calculated: early enhanced T1-rt (eT1), early T1-rt shortening (eT1sh), and early relative T1-rt shortening (erT1sh). Optimal cut-off values and their diagnostic performances in the identification of AM were calculated.
Results: In AM patients, median eT1 was 275.6 ms [252-297], eT1sh was 75% [73%-78%], and erT1sh was 2.15 [1.83-2.59], all being significantly higher with respect to HC (p=0.0014, p<0.0001, and p<0.0001, respectively). eT1sh showed the best diagnostic performance with excellent AUC (97%, 95% confidence interval, CI: [93%-100%]). A reduction of eT1sh ≥69.5% identified AM with very

high sensitivity (93%), specificity (100%), NPV (83%), PPV (100%), and accuracy (95%). eT1 had a good AUC (92.5%, 95% CI: [86%-99%]), slightly worse than eT1sh. eT1≤331 ms identified AM with 93% sensitivity, 87% specificity, 81% NPV, 95% PPV, and 91% accuracy. erT1sh showed the worst diagnostic performance with 78% AUC (95% CI: [66%-91%]). erT1sh>1.9 identified AM with 68% sensitivity, 87% specificity, 50% NPV, 93% PPV, and 73% accuracy.
Conclusion: eT1sh showed the best diagnostic performance in the identification of AM. It can be a promising alternative method for the detection of hyperemia in AM.
Limitations: A relatively small sample size.
Ethics committee approval: The study was approved by the Institutional Review Board. Written informed consent was obtained.
Funding: The study was partially granted by the Italian Ministry of Health

RPS 1803-7 11:06

Derived-CMR strain efficacy in myocardial inflammation: a retrospective comparison with standard practice

P. Palumbo, C. de Cataldo, S. Torlone, G. Campidoglio, F. Cobianchi Bellisari, F. Sgalambro, S. Necozione, E. Di Cesare, C. Masciocchi*; L'Aquila/IT (palumbopierpaolo89@gmail.com)*

Purpose: A major role in the diagnosis of myocarditis is played by new CMR-based biomarkers. The aim of the study was to investigate the diagnostic capabilities of tissue-tracking (TT) strain analysis in patients with a CMR-based diagnosis of myocarditis.
Methods and materials: 43 patients with a CMR-based diagnosis of myocarditis according to the standard Lake Louise criteria were retrospectively analysed. 27 healthy participants were selected as a control group. Cine-RM data was used for the analysis. Dedicated TT-software was used to perform radial, circumferential, and longitudinal strain for global, per-plane (basal, middle, and apical), and segmental (AHA 16-segments standard) evaluation in short and long-axis left ventricle images.
Results: Patients with myocarditis showed significantly reduced LV radial and circumferential strain values, both in global and per-plane evaluation (GRS: 23.39 ±7.16% vs. 31 ±7.15%)(GCS: -14.90 ±3.69% vs. -18.21 ±2.52%)(RSbas: 21.92 ±6.47% vs. 29.25 ±6.28%)(CSbas: -14.21 ±3.38 vs. -17.50 ±2.46%), compared with healthy participants. Good accuracy was found according to the ROC analysis (AUC up to 0.824). No significant correlations were found with oedema, while a significant correlation was found between segmental radial and LE (p-value:0.019), and an interesting trend between segmental circumferential and LE (p-value:0.087).
Conclusion: Tissue-tracking strain analysis has proved accurate in the evaluation of patients diagnosed with myocarditis based on standard Lake Louise criteria. Tissue-tracking strain analysis could improve diagnostic accuracy in clinical practice, adding useful information over the standard findings.
Limitations: A lack of mapping sequence, especially in elderly examination, does not permit an adequate comparison with revisited Lake Louis criteria.
Ethics committee approval: The study was conducted in accordance with the declaration of Helsinki.
Funding: No funding was received for this work.

Coronary inflammation by CT pericoronary fat attenuation in MINOCA and Tako-Tsubo syndrome

N. Gaibazzi, C. Martini, A. Botti, A. Pinazzi, B. Bottazzi, A. Palumbo*; Parma/IT (alepalumbo@gmail.com)*

Purpose: The pericoronary fat attenuation index (pFAI) emerged as a marker of coronary artery inflammation (CAI), measurable by standard coronary CT angiography (CCTA). It compares well with the gold standard for the CAI assessment and can predict future cardiovascular events. pFAI could prove invaluable in differentiating CAI from a noninflammatory status, helping to unravel the mechanisms subtending an event classified as myocardial infarction with nonobstructive CA (MINOCA) or Tako-Tsubo syndrome (TTS).
Methods and materials: Patients admitted with MINOCA and TTS between 2011-2018, who had both CCTA and cardiac MR during/shortly after the acute phase, were selected and pFAI measured in their CCTA. pFAI was also measured in control subjects who had CCTA for atypical chest pain workup, no obstructive CAD found in their CCTA, and no cardiac events at a 2-year follow-up.
Results: In the n=106 MINOCA/TTS, mean pFAI was 68.378.29 vs. 78.036.20 in the n=106 controls (P<0.0001), and the difference confirmed also when comparing mean pFAI in each CA between MINOCA/TTS and controls (P<0.0001). Nonobstructive coronary plaques at CCTA, high-risk plaques in particular, were more frequently found (P<0.01) in the MINOCA/TTS group versus controls.
Conclusion: In MINOCA and TTS pts, CCTA is not only able to detect angiographically invisible atherosclerotic plaques, but its diagnostic yield can be expanded using the simple measurement of pFAI to characterise pericoronary fat tissue. In MINOCA/TTS, mean pFAI demonstrates higher values compared with controls, a finding that has been associated with CAI.
Limitations: The drug therapy was not recorded. We cannot exclude an effect of drugs used in acute coronary syndromes on pFAI in our MINOCA/TTS group.
Ethics committee approval: The study was approved by Institutional Review Board and Research Ethics Committee and all subjects gave written informed consent.
Funding: No funding was received for this work.

Differentiating chronic myocarditis from non-ischemic dilated cardiomyopathy using segmental T1 mapping

M. T. A. Wetscherek[1], C. Lücke[2], P. Lurz[2], M. Gutberlet[2]*; [1]Cambridge/UK, [2]Leipzig/DE*

Purpose: To determine the T1-relaxation time differences between chronic myocarditis (CM) and non-ischemic dilated cardiomyopathy (DCM) using an overall and segmental approach on native T1 mapping.
Methods and materials: We performed a retrospective analysis of 62 cases, including 52 consecutive patients who had a presentation at >14 days from initial symptoms and underwent CMR as part of a complete diagnostic work-up for clinically suspected myocarditis in accordance to current guidelines. 26 patients were included in each of the CM and DCM groups and 10 individuals served as normal controls. The CMR protocol at 1.5T included non-contrast T1-mapping using a 5(3)3 MOLLI acquisition. We analysed a mid-myocardial slice for overall and segmental myocardial T1-relaxation. A Wilcoxon rank sum test was used to assess the differences between the groups.
Results: The overall median and interquartile range was 1060 [1002-1155] ms for CM and 1058 [1034-1093] ms for DCM, showing no significant difference between the two groups. The overall T1-relaxation time was significantly higher in both groups compared to controls, T1-relaxation 1007 [966-1036] ms, (p<0.05). In CM, we found no statistical difference in T1-relaxation between the lateral and septal segments, while the septal values were significantly higher compared to the values in the lateral wall segments in DCM (p<0.001). We found significantly higher T1-relaxation in the inferoseptal segment in DCM, 1120 [1088-1154] ms, compared to CM, 1075 [1042-1136] ms, (p=0.04).
Conclusion: A per-segment approach can help to differentiate chronic myocarditis and non-ischemic DCM, while an overall approach can only differentiate both groups from healthy subjects.
Limitations: The small sample size.
Ethics committee approval: This study approved by the institutional ethics committee. Written informed consent was obtained.

RPS 1803-10 11:24

A multiparametric native CMR approach to acute and chronic cardiac diseases with increased myocardial mass using mapping and feature-tracking strain

M. C. Halfmann, S. Benz, C. Düber, R. Kloeckner, T. Muenzel, P. Wenzel, K.-F. Kreitner, T. Emrich; *Mainz/DE (Moritz.Halfmann@gmx.de)*

Purpose: The diagnoses of acute myocarditis (AM) and hypertensive heart disease (HHD) remain difficult and are commonly based on a combination of clinical expertise and a multi-parameter diagnostic workup including contrast-enhanced cardiac magnetic resonance imaging (CMR). It was our purpose to evaluate a multiparametric set of native imaging parameters for their diagnostic accuracy.
Methods and materials: A total of 33 AM and 21 HHD patients who had been referred to our department between 09/2014 and 09/2017, as well as 50 carefully selected healthy volunteers, (HV) underwent CMR at 3T. Subsequent feature-tracking strain analysis and native T1/T2 mapping were performed and results were processed in the form of binary logistic regressions. Cut-off values, areas under the curve (AUC), and corresponding sensitivities and specificities were derived from receiver operator characteristic curves.
Results: For HV vs AM, the combination of global circumferential strain, myocardial mass per body surface area (MYM), and T1 values performed best (AUC .92, 94% sensitivity, 76% specificity). In HV vs HHD, the triad of global longitudinal strain, MYM, and T1 values discriminated best between groups (AUC of .99, 100% sensitivity, 84% specificity), and in AM vs HHD, the combination of GLS, MYM, and T2 values outperformed all others (AUC .92, 90% sensitivity, 76% specificity).
Conclusion: Different distinct pathophysiologies behind the diseases lead to different sets of best-performing parameters. The proposed multiparametric approaches were able to precisely discriminate between healthy individuals and patients, as well as different patient populations, without the need for contrast agents.
Limitations: The retrospective design prevented endomyocardial biopsies as the current gold standard for diagnosing AM. However, because of the invasiveness and possible sampling errors, only few patients routinely have biopsies in clinical routine.

Gender-neutral FT-CMR strain ratios improve the discriminatory accuracy in acute and chronic heart conditions

M. C. Halfmann, S. Benz, C. Düber, R. Kloeckner, T. Muenzel, P. Wenzel, K.-F. Kreitner, T. Emrich; *Mainz/DE (Moritz.Halfmann@gmx.de)*

Purpose: Hypertensive heart disease (HHD) and acute myocarditis (AM) can both present with increased myocardial mass despite different pathophysiology. The differentiation between them remains difficult. The accompanying distinct patterns of altered myocardial deformation, however, can be investigated using a feature tracking (FT)-CMR strain. Hence, the aim was to evaluate whether new strain ratios including the myocardial mass per body surface area (MyoMass/BSA) yield additional value in the differentiation between both diseases and healthy volunteers.
Methods and materials: Patients with AM (n=43) and HHD (n=28) underwent CMR at 3T between 09/2014 and 09/2017. A group of 61 healthy volunteers (HV) served as normal controls. FT-strain analysis was performed and natural strain values were evaluated for gender and age-specific differences. Subsequently, gender-neutral strain parameters were calculated and indexed to the MyoMass/BSA, leading to ratio strains. These were then evaluated for their discriminatory accuracy by means of areas under the curve (AUC), sensitivity, and specificity.
Results: There were statistically significant differences in strains between genders ($p<0.05$) but not between age groups. For the differentiation between HV and AM, the global circumferential strain ratio performed best (AUC 0.86, 79% sensitivity, and 82% specificity). In discriminating between HV and HHD, as well as AM and HHD, the global longitudinal strain ratio outperformed all other parameters (AUCs 0.96/0.79, 92%/89% sensitivity, and 86%/66% specificity, respectively).
Conclusion: The calculated ratios provide additional value in the differentiation of diseases with increased myocardial mass. As there is no need for additional sequences, time, or even contrast agents, strain ratios have the potential to be a powerful addition into currently developing multiparametric native diagnostic approaches.
Limitations: The etrospective design did not allow for endomyocardial biopsies.

The prevalence and spectrum of cardiovascular MR features of myocardial infarction with non-obstructed coronary arteries: first results from the First Moscow City Hospital registry

E. Pershina, V. E. Sinitsyn, A. Shilova, D. Shchekochikhin, M. Gilyarov, A. Nesterov, A. Svet; *Moscow/RU (pershina86@mail.ru)*

Purpose: To analyse cardiovascular MR (CMR) features in myocardial infarction with non-obstructed coronaries (MINOCA) patients in an emergency hospital.
Methods and materials: The registry included the consecutive patients presenting to the emergency department between 2018 and 2019 with cardiac chest pain, elevated troponin (>0.04 ng/ml), and non-obstructed coronaries (according to results of cardiac catheterisation). They were referred to CMR performed with 1.5T scanner including cine-MR, T2-weighted images, and sequences with late gadolinium enhancement (LGE). Patients were divided into 4 categories based on their CMR findings: myocardial infarction (MI), myocarditis, hypertrophic cardiomyopathy (HCM), and normal CMR. Cases with apical ballooning without LGE were diagnosed as takotsubo syndrome (TS).
Results: 28 MINOCA patients (average age 61.6±13.4, 44% male) were included in the registry. CMR was performed 8 days (median) after patients' admission. 32.1% of patients presented with ST-elevation MI (STE). The average troponin T level was 0.64±0.18 ng/ml. CMR was able to identify the cause for the troponin rise in 75% of the patients. 25% of them had myocarditis, 25% acute MI, 13.2% HCM, and 7.1% TS. The results of CMR were normal in 25%. There was no difference between patients with and without ST-segment elevation according to the patterns of MR findings (p=0.6). Troponin levels, age, and sex did not significantly differ between the groups (p=0.15, p=0.29, and p=0.11, respectively).
Conclusion: The registry preliminary revealed that patients with MINOCA represent a heterogeneous cohort with different underlying causes with similar clinical and demographical data. CMR was able to establish the correct diagnosis in 75% of cases. There is a probability that the prevalence of TS was underestimated due to substantial time gap between admission and CMR.
Limitations: A single-centre registry.

Correlation between native T1 and T2 mapping and MRI strain parameters in patients with myocarditis: a pilot study

M. Muca[1], L. Pagnan[2], M. G. Belgrano[1], M. A. A. Cova[1]; *[1]Trieste/IT, [2]Sgonico/IT*

Purpose: To research the correlation between T1 and T2 mapping and feature tracking parameters in cases of myocarditis and comparison of T1 and T2 mapping values between patients with myocarditis and those considered at low-risk of cardiomyopathy.
Methods and materials: 28 patients (19 with myocarditis; 9 at low-risk of cardiomyopathy) were enrolled retrospectively from November 2017 to October 2018. All patients underwent standard cardiac magnetic resonance (CMR) and T1 and T2 mapping sequences. Mapping and strain parameter evaluation were performed with two dedicated softwares.
Results: Native T1 mapping values for a basal slice and T2 mapping values for basal and apical slice were significantly increased in patients with myocarditis compared to low-risk patients (p-value, respectively, 0.03, 0.04, and 0.05).
A positive and significant correlation (p=0.02) between increased values of T1 mapping for a medium slice and decreased peak longitudinal strain in patients

with myocarditis was observed. Also, a positive correlation between increased native T1 mapping values and decreased values of peak circumferential strain (p=0.01), peak short-axis radial strain (p = 0.009), and peak long axis radial strain (p=0.02) was observed for the medium slice in these patients.
Conclusion: Our study suggests the utility of systematic use of T1 and T2 mapping sequences and feature tracking analysis in CMR as an integral part of the diagnosis and management of myocarditis identifies potentially high-risk patients with latent ventricular dysfunction.
Limitations: In our institution, reference values of T1 and T2 mapping aren't yet available. A higher prevalence of susceptibility artefacts in the inferolateral region was observed. Endomyocardial biopsy was performed only in one case of myocarditis. The small sample of patients enrolled may have influenced the results we obtained.

RPS 1803-14 11:48
Cardiac CT with triple-rule-out (TRO) and late iodine enhancement (LIE) acquisition in the evaluation of patients presenting with acute troponin elevation
D. Vignale[1], A. Palmisano[1], E. Boccia[1], M. Gatti[2], R. Faletti[2], F. Moroni[1], D. de Stefano[3], F. de Cobelli[1], A. Esposito[1]; *[1]Milan/IT, [2]Turin/IT, [3]Rome/IT (vignale.davide@hsr.it)*

Purpose: To evaluate the diagnostic yield of the late iodine enhancement (LIE) acquisition added to the triple-rule-out CT (TRO-CT) performed in patients presenting with acute symptoms and troponin elevation without clinical/electrocardiography criteria for acute myocardial infarction (AMI).
Methods and materials: 60 consecutive patients with acute symptoms, troponin elevation, and no diagnostic criteria for AMI underwent TRO-CT to diagnose acute aortic syndromes, obstructive coronary artery disease (CAD-RADS≥4), and pulmonary embolism (PE). Patients with a negative TRO-CT underwent LIE acquisition to evaluate the presence and pattern of LIE and to quantify the myocardial extracellular volume fraction (ECV). Obstructive CAD was confirmed by invasive coronary angiography and myocardial disease by cardiac magnetic resonance.
Results: The male to female ratio was 35:25. The median age was 71 years [IQR=47-78]. Peak median troponinT (n=46) was 49.0 ng/L[IQR=20.4-195.7] and peak median troponinI (n=14) was 4.1 ng/L[IQR=1.2-11.8]. Reported symptoms were chest pain (n=31[51%]), dyspnoea (n=16[26%]), palpitations (n=6[11%]), loss of consciousness (n=5[8%]), and other (n=14[23%]). TRO-CT identified 19 (32%) obstructive CAD, 1 (1%) acute aortic syndrome, 5 (8%) PE, 1 (1%) CAD+PE, and 1 (1%) CAD+acute aortic syndrome. LIE acquisition was performed in the remaining 33 (55%) TRO-negative patients. 2 (3%) had LIE with ischemic pattern, 16 (27%) LIE with non-ischemic pattern [13 (22%) myocarditis, 3 (5%) idiopathic dilated cardiomyopathy], 3 (5%) increased ECV suggestive for amyloidosis, 2 (3%) cardiac metastasis, 2 (3%) tako-tsubo cardiomyopathy, 1 (1%) pericarditis, and 1 (1%) basal hyperdensity of myocardium suggestive for haemosiderosis. 6 (10%) patients were negative to TRO and LIE and did not report major cardiovascular adverse events after a mean follow-up of 419 days.
Conclusion: LIE acquisition increases the diagnostic value of TRO-CT, finding a diagnosis in 82% of TRO-negative patients and allowing a safe discharge of TRO- and LIE-negative patients.
Limitations: A single-centre study, small sample size, and short follow-up.
Ethics committee approval: The study was approved by the institutional review board.
Funding: No funding was received for this work.

Pericardial effusion is a marker of increased cardiac mortality in thalassemia major patients
A. Meloni[1], L. Pistoia[1], G. Restaino[2], N. Schicchi[3], R. Righi[4], A. Vallone[5], N. Dello Iacono[6], V. Positano[1], A. Pepe[1]; *[1]Pisa/IT, [2]Campobasso/IT, [3]Ancona/IT, [4]Ferrara/IT, [5]Catania/IT, [6]San Giovanni Rotondo/IT (alessia.pepe@ftgm.it)*

Purpose: This is the first prospective study evaluating if the presence of pericardial effusion (PE) is associated with increased cardiac mortality in thalassemia major (TM).
Methods and materials: 1,259 patients (648 females, 31.02±8.64 years) enrolled in the MIOT were prospectively followed from their first CMR scan. CMR was used to quantify myocardial iron overload (MIO) by a multislice T2* approach and to assess biventricular function parameters and PE by cine sequences.
Results: PE was present in 25 (2.0%) patients. Patients with and without PE were comparable for age, sex, percentage of patients with MIO (global heart T2*<20 ms), and biventricular parameters. The mean follow-up time was 44.55±20.35 months and there were 15 deaths, 9 due to cardiac causes. Cardiac mortality was greater for patients with PE versus those without PE (8.0% vs 0.6%, P=0.013). PE was a significant predictive factor for cardiac death (hazard ratio-HR=19.25, 95%CI=3.96-93.66, P<0.0001. PE remained a significant prognosticator for death also in a multivariate model including MIO.
Conclusion: PE is quite rare in TM patients and is not related to MIO, but an important role in its development could be played by the 'iron-induced' pericardial siderosis. PE is a strong predictor for cardiac death, independent from the presence of MIO. The non-invasive diagnosis of PE is important for a more complete definition of the cardiac involvement of TM patients and the estimation of the prognosis.
Limitations: A low number of events.
Ethics committee approval: The study complied with the Declaration of Helsinki. All patients gave their informed consent. The project was approved by the institutional ethics committee.
Funding: The MIOT project receives "no-profit support" from industrial sponsorships (Chiesi Farmaceutici S.p.A. and ApoPharma Inc.).

Multiparametric intraoral ultrasound of oral lesions: the correlation of B-mode, contrast-enhanced ultrasound, and shear-wave elastography with histopathology
M. Lu, T. Wei*; Chengdu/CN*

Purpose: To evaluate the diagnostic value of multiparametric ultrasound consisting of B-mode intraoral ultrasound, contrast-enhanced ultrasound (CEUS), and shear-wave elastography (SWE) in identifying benign and malignant oral lesions.
Methods and materials: A consecutive series of 29 patients (age range, 31-81 years; mean 61±12 years; 18 male and 11 female) were evaluated in this study retrospectively. B-mode, CEUS, and SWE examinations were performed in each case using an endocavitary transducer prior to operation. The quantitative parameters were recorded for each modality. The diagnostic performances of each modality and their combined use were evaluated with the receiver operating characteristic (ROC) curve and descriptive statistics.
Results: Of the 32 lesions, there were 21 malignant lesions and 11 benign lesions. Compared with separate B-mode, CEUS, and SWE examination, multiparametric ultrasound showed the highest value in sensitivity, specificity, PPV, NPV, and overall accuracy of 90.5%, 81.8%, 90.5% 81.8%, and 87.5%, respectively. Multiparametric ultrasound achieved larger area under the curve

(AUC) in ROC curve analysis and reduced the number of false-positive findings significantly (P<0.05).
Conclusion: Multiparametric intraoral ultrasound consisting of B-mode, contrast-enhanced ultrasound, and shear-wave elastography yields additional valuable quantitative data to single ultrasound modalities for the diagnosis of oral lesions.
Limitations: This study design was retrospective and the sample size was relatively small.
Ethics committee approval: Institutional Review Board and Ethics Committee of Sichuan Cancer Hospital was approved for this retrospective study and informed consent was obtained for every patient.
Funding: No funding was received for this work.

High-resolution ultrasonography (HRUS) in periapical dental lesions
R. Rastogi, N. Jain*; Moradabad/IN (rajulrst@yahoo.co.in)*

Purpose: To evaluate the efficacy of high-resolution ultrasonography (HRUS) in the diagnosis of periapical lesions. Conventionally, the diagnosis of periapical lesions of the teeth has been based on clinical, radiological, and histopathological examinations. However, conventional radiological procedures do not allow for the differentiation between cystic and non-cystic periapical lesions. Recently, USG has been used to provide more detailed information. Limited studies have been done to evaluate periapical lesions using USG with colour Doppler and power Doppler.
Methods and materials: 60 patients having inflammatory periapical lesions of maxillary or mandibular anterior teeth and requiring endodontic surgery were included in this study. We used conventional periapical radiographs as well as USG with colour Doppler and power Doppler for the diagnosis of these lesions. Their diagnostic performances were compared against histopathologic examination.
Results: HRUS examination with colour Doppler and power Doppler identified 58 (38 cysts and 20 granulomas) of 60 periapical lesions accurately, with a sensitivity of 100% for cysts and 90.91% for granulomas, and a specificity of 90.91% for cysts and 100% for granulomas. In comparison, conventional intraoral radiography identified only 42 lesions (sensitivity of 78.9% for cysts and 45.4% for granulomas, and specificity of 45.4% for cysts and 78.9% for granulomas).
Conclusion: HRUS imaging with colour Doppler and power Doppler is superior to conventional intraoral radiographic methods for diagnosing the nature of periapical lesions in the anterior jaws. This study reveals the potential of USG examination in the study of other jaw lesions.

RPS 1808-3 10:42
B-mode, colour Doppler, and shear-wave elastography ultrasound features to predict cervical traumatic neuromas after lateral neck dissection in thyroid cancer patients: a cross-sectional study
V. Marcos, F. L. Pereira, M. Schelini, M. H. Tsunemi, R. B. Domingues, M. Kulcsar, A. O. Hoff, M. C. Chammas, R. M. C. D. Freitas*; São Paulo/BR (ricardomcfreitas@gmail.com)*

Purpose: Cervical traumatic neuromas (CTN) following lateral neck dissection for thyroid cancer may be misdiagnosed as metastatic lymph nodes. The purpose of this study was to present the B-mode, colour Doppler, and shear-wave elastography (SWE) ultrasound (US) features of the CTNs and the differences from lymphadenopathies.
Methods and materials: 79 patients with US CTNs features were selected from 206 patients who underwent cervical US after neck dissection if the following was present: 1) nodule continuity with cervical plexus, 2) posterolateral location, 3) fusiform morphology, 4) hypoechogenic internal lines, and 5) Doppler-flow absence. 31 patients (group 1, n=38 nodules) underwent fine-needle aspiration biopsy (FNAb). Two radiologists blinded to the cytological results evaluated 26 patients (n=31 nodules, group 1) with B-mode, colour Doppler, and SWE. US features (except SWE) were then compared to 42 patients (n=48 nodules, group 2) who had biopsy-proven metastatic (n=32) or reactive lymphadenopathies (n=16).
Results: All group 1 nodules had a CTN diagnosis according to cytologic confirmation (n=15) and pain exacerbation during nodule puncture and undetectable thyroglobulin/calcitonin in FNAb washout fluid (n=38). B-mode, colour Doppler, and SWE US features were similar (p>0.05) between the biopsy-proven (n=11) and indeterminate-cytology CTNs (n=20). CTNs had a mean elastic score of 2, a shear-wave velocity of 3.2±0.5 cm/s, and an elasticity index of 33.3±11.3 kPa. The above-mentioned US CTNs features such as 1) and 4) showed a sensitivity, specificity, and accuracy of 0.95, 0.93, and 0.98, and 0.92, 1.00, and 0.97, respectively, to differentiate the CTNs from cervical metastatic or reactive lymphadenopathies.
Conclusion: Continuity with the cervical plexus and the hypoechogenic internal lines with a moderate soft elastic score were the key US features for CTNs.
Limitations: The small population was a study limitation.
Ethics committee approval: IRB approval and written informed consent was obtained.
Funding: No funding was received for this work.

RPS 1808-4 10:48
Role of B-scan USG as a primary tool in closed globe ocular blunt trauma and correlation with ophthalmoscopy and intraoperative observations: a study from a resource-poor hospital in rural India
S. Ghosh[1], J. Bardhan[2], A. Mondal[3], T. Dhibar[2]*; [1]Birbhum/IN, [2]Kolkata/IN, [3]Bankura/IN (samikghosh1988@gmail.com)*

Purpose: Blunt ocular trauma is a leading cause of acquired blindness globally, encompassing all age groups. This study intends to illustrate the role of high-frequency ultrasonography in accurately describing different ocular pathologies, especially those involving posterior segment, and comparing these findings with those observed during ophthalmoscopy and/or surgical exploration whenever feasible.
Methods and materials: In this 1-year-long descriptive study, conducted in a rural Indian hospital, high-frequency (HF, 5-12 MHz) USG was performed in 111 patients, irrespective of age, with a history of blunt ocular trauma within the last 2 years. Ocular findings were observed. Patients with active surface infection, impending/frank globe rupture and pre-existing ocular disorders were excluded. Routine ophthalmoscopic examination and operative interventions were done whenever necessary. Statistical analysis was conducted at the end.
Results: HF-USG proved to be comparable to ophthalmoscopy in terms of sensitivity and specificity. Vitreous haemorrhage (VH) was the most commonly detected pathology (49.5%), followed by retinal detachment (19.8%) and traumatic cataract (18.9%). Among VH, 27.2% were in combination with retinal detachment (RD) and cataract, while 16.4% in combination with posterior vitreous detachment (PVD). For VH, USG sensitivity and specificity was 100% and 93%. For other pathologies, specificity was 100% for all except PVD (97%). Sensitivity was 100%, 91%, 86%, 80%, and 70% for choroidal detachment, retinal detachment, PVD, ectopia lentis, and cataract, respectively. VH had a significant correlation with posterior vitreous detachment, choroidal detachment, traumatic cataract, post-traumatic ectopia lentis, and small globe size (p<0.05). Traumatic cataract had significant correction with traumatic ectopia lentis and day of presentation after injury (p<0.05)
Conclusion: HF-USG is an accurate and sensitive modality, especially in resource-poor hospitals, for the short/long-term assessment of posterior segment ocular pathologies due to ocular blunt trauma.
Limitations: A loss to follow-up.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

RPS 1808-5 10:54
A 2-year retrospective analysis of the diagnostic performance of core-needle biopsy (CNB) versus fine-needle aspiration cytology (FNAC) in the evaluation of parotid gland lesions
Z. Saloojee, F. Hosseini-Ardehali*; London/UK (zzsaloojee@gmail.com)*

Purpose: To compare the relative diagnostic performance of FNAC and CNB in parotid gland (PG) lesions.
Methods and materials: Data from FNAC and CNB performed over a 2-year period was reviewed. Samples were included if the clinico-radiological suspicion was a PG neoplasm. Biopsies of lesions arising outside the PG, metastases, and microbiological aspirations were excluded as were recurrent pleomorphic adenomas. For excised lesions, final histopathology was assessed for concordance with the biopsy samples.
Results: 183 biopsies were obtained: 154 FNAC and 77 CNB. Of 154 FNAC, 27 were inadequate (82% adequacy rate), 85 yielded a cytological diagnosis (67% diagnostic rate), and 48 subsequently underwent CNB. From 76 CNB, 74 samples were adequate for diagnosis (97%) and 61 yielded a histopathological diagnosis (80%). Of 12 inadequate FNAC who had a CNB, 10 (83%) were diagnostic. In 68 of 183 patients, final excision histopathology was obtained: 82% FNA concordance and 92% CNB concordance. FNA sensitivity for malignancy was 60.0% (95% CI: 14.66%-94.73%) and FNA specificity was 90.2% (95% CI: 76.87-97.28%). CNB sensitivity was 100.00% (95% CI: 73.54%-100.00%) and specificity was 93.75% (95% CI: 69.77%-99.84%).
Conclusion: CNB demonstrates superior performance with regard to sensitivity, specificity, and histopathological concordance compared to FNA, with no complications in our study. This study is in line with published studies in this field suggesting the preferential use of CNB over FNA may be warranted in the evaluation of primary PG lesions.
Limitations: This was a retrospective, observational study. In cases where the cytology/histology was equivocal, interpretation was made by the authors on the final interpretation by consensus.
A relatively low number of lesions with final histopathological data (n=68) compared to total biopsy sample size (n=183).
Ethics committee approval: n/a
Funding: No funding was received for this work.

The added value of preoperative multiparametric ultrasound in primary hyperparathyroidism: correlation with scintigraphy and histology
S. Pavlovics, M. Radzina, A. Ozolins, Z. Narbuts, P. Prieditis, M. Tirane*; Riga/LV (pavlovics.sergejs@gmail.com)*

Purpose: To evaluate the sensitivity and specificity of ultrasound and scintigraphy findings of histologically confirmed hyperplastic and neoplastic parathyroid glands in patients with primary hyperparathyroidism.
Methods and materials: This was a prospective study (02.2019–until this moment). 37 patients (aged 49-77 years, of whom 31 were women) with primary hyperparathyroidism scheduled for parathyroidectomy in Pauls Stradins Clinical University Hospital (PSKUS) were enrolled in the study. B-mode ultrasound, colour Doppler, superb microvascular imaging, elastography (strain-ratio and shear-wave, compared to the thyroid gland), contrast-enhanced ultrasound (SonoVue 2ml+Sol. NaCl 0.9% 10ml bolus) images were obtained and postprocessing performed. Results were compared with scintigraphy and postoperative histology.
Results: 48 suspicious nodules were surgically removed, of which 26 were solitary adenomas and 4 atypically localised adenomas. 4 patients had more than one parathyroid lesion. Most characteristic ultrasound features of parathyroid adenomas were hypoechoic, well-defined lesions with increased echogenicity in the central part (79%) and peripheral-central vascularisation (67%) with feeding vessel (100%), with the average size of an adenoma being 1.4x0.8 cm. Adenomas presented as soft lesions on elastography (average SR 0.98kPa and average 2D-SWE 21kPa). CEUS showed peripheral hypervascularity in the early arterial phase (median=9s), quickly reaching peak contrast concentration (median=16s), following early wash-out (median=30s). The most common histological type of adenoma was a chief-cell adenoma. Multiparametric ultrasound had a sensitivity and specificity of 91% and 58%, respectively, PPV 86% and NPV 70% compared to scintigraphy 69% and 43%, PPV 80%, NPV 30%, and a combination of both methods achieved a sensitivity of 95%, specificity 45%, PPV 75%, and NPV 83%.
Conclusion: Multiparameter ultrasound showed better sensitivity and specificity compared to scintigraphy, but combining both modalities improved sensitivity.
Limitations: An insufficient amount of patients.
Ethics committee approval: University of Latvia and PSKUS ethics committee approval and written informed consent was obtained.

Predictive value of head and neck CT arteriography in the intraoperative bleeding volume of carotid body tumours
Y. Chen, T. Su, H. Liu, Z. Jin, Z. Zhang, Y. Qi, J. Wang*; Beijing/CN (bjchenyu@126.com)*

Purpose: To investigate the predictive value of head and neck CT angiography (CTA) in intraoperative haemorrhage of carotid body tumours.
Methods and materials: Head and neck CT images of 36 patients with carotid body tumours confirmed by pathology were retrospectively analyzed. The intraoperative bleeding volume ＜500 ml group and intraoperative bleeding volume ≥500 ml group were compared and analysed. The patient's age, sex, Shamblin classification, size of the lesion, number of blood supply arteries, course of the disease, plain scan, and enhanced CT value were analysed. The ROC curve was established to determine the number of blood supply arteries, the maximum diameter of upper and lower, the longest diameter of the axis, and the sensitivity and specificity of the Shamblin type in judging the blood volume during the operation.
Results: The amount of bleeding during the operation of carotid body tumours is related to the age of the patients, the maximum diameter of tumours, the longest diameter of axes, Shamblin classification, and the number of blood supply arteries. The AUC of the number of blood supply artery is larger than the other parameters, which can better predict intraoperative blood loss in patients with CBT.
Conclusion: The number of blood supply artery detected in CTA is the best parameter to predict intraoperative blood loss.
Limitations: The selected cases are few and lack of validation of research. Dual-energy data wasn't analysed.
Ethics committee approval: This retrospective study was performed with institutional review board approval. Informed consent was obtained.
Funding: Prof. Zhengyu Jin received research grants from National Public Welfare Basic Scientific Research Project of Chinese Academy of Medical Sciences (2018PT32003).

Characterisation of head and neck paragangliomas by multiparametric MR imaging: a comparison with other deep soft-tissue tumours of the neck
E. Arsovic, S. Akkari, U. Scemama, M. Montava, J. P. Lavieille, N. Fakhry, D. Taieb, A. Varoquaux*; Marseilles/FR*

Purpose: To identify quantitative MR biomarkers that allow distinction between paragangliomas and other deep soft-tissue tumours of the neck.
Methods and materials: A retrospective review of head and neck paragangliomas (HNPGL) patients evaluated by both ^{18}F-DOPA PET/CT, and time-resolved MRA sequences, between 2009-2019 was performed. A control group of 36 vascular space lesions (33 patients), investigated during the same period, was also analysed, including nerve sheath tumours, metastatic lymph nodes from squamous cell carcinomas or from UCNT, arterio-venous malformations, and temporal bone meningiomas. Semi-quantitative parameters of enhancement were extracted from time-intensity curves on time-resolved MRA sequences and ADC was assessed for each lesion. The image quality of curves was scaled (1-3). A gold standard was obtained for all cases.
Results: 50 patients with 60 HNPGL were included, including 20 patients with germline mutations in one of the SDH genes (SDHx). All semi-quantitative parameters extracted from time intensity-curves were significantly different between HNPGL and other vascular space tumours, including wash-in obtained par linear regression, time-to-peak, and wash-out. Nerve sheath tumours exhibited higher ADC values than lymph nodes. Classification and a regression tree (CART) clearly distinguished HNPGL from other tumours with a very high accuracy. The features were also shown and formed distinct groups on principal

component analysis. No significant difference was observed between sporadic and SDHx mutated HNPGL.
Conclusion: Our study clearly identifies a multiparametric MRI signature of paragangliomas that provides a strong impetus for switching from qualitative to quantitative analysis of deep soft-tissue tumours of the neck.
Limitations: A retrospective study, a limited number of patients, and various MRA sequences, althought this allows for comparison between them.
Ethics committee approval: The study was approved by an institutional review board.
Funding: No funding was received for this work.

Abbreviated MRI protocol in head and neck imaging: an alternative approach in the imaging of tumours in the head and neck

C. Loberg, B. Turowski, C. Rubbert, P. D. K. Scheckenbach, M. Kaschner, J. Caspers, D. Jansen, H. Nasri*; Düsseldorf/DE (christina.loberg@med.uni-duesseldorf.de)*

Purpose: Patients suffering from cancer of the head and neck are often impaired when undergoing head and neck MRI. Quality of MRI imaging is often impaired and appropriate assessment is not possible. We investigated whether an abbreviated protocol (AP) was suitable for patient assessment.
Methods and materials: We conducted a retrospective observational reader study in 480 studies of 377 patients suspected of having a tumour of the head and neck, recurrence or metastasis. Expert radiologists reviewed the T2w and pre- and postcontrast images first to search for significant enhancement in correlation to anatomic region. Thereafter, the regular full diagnostic protocol (FDP) consisting of additional DWI, STIR coronal, and T1w fatsat pre- and post-contrast in transversal and coronal orientation was analysed.
Results: MRI acquisition time for FDP was 17:53 min versus 9:82 min for the AP. Average time to read the complete AP was 5:30 min versus 11 min for the FDP. The comparison of diagnostic accuracy did not differ significantly between reading the AP and the complete FDP protocol (100%). NPV was high with 98.9% for complete AP and FDP readings. The specificity and positive predictive value of AP readings did not differ significantly from those of FDP reading (95.3% vs 94.8%).
Conclusion: Abbreviated MRI of the head and neck could be a viable alternative to a full-diagnostic protocol to minimise artefacts and improve patients compliance. In the case of unclear findings, additional MRI sequences can be added.
Limitations: A single-centre study in patients with different kind of malignancies of the head and neck with different treatments. The examination was performed at 1.5 to 3T field strength.
Ethics committee approval: Ethic committee approval and informed written consent obtained.
Funding: No funding was received for this work.

RPS 1808-10 11:24

Detection of laryngeal and hyoid fractures in forensic post-mortem CT: a comparison of standard post-mortem CT with dedicated high-resolution cervical CT acquisitions

A. M. Bucher[1], S. Heinbuch[2], A. Koppold[1], D. M. Kettner[1], P. D. M. Verhoff[1], M. Beeres[3], B. Bodelle[1], T. J. Vogl[1]; *[1]Frankfurt am Main/DE, [2]Homburg/DE, [3]Rüsselsheim/DE*

Purpose: To evaluate the detection rate of laryngeal and hyoid fractures in suspected homicide victims with suspicion of strangulation in forensic CT imaging and high-resolution reconstructions from dedicated laryngeal CT against autopsy findings.
Methods and materials: We included 20 consecutive post-mortem head and neck CT examinations (third-generation dual-source CT). For each case, a standard-of-care head and neck spiral (CT_N) and an additional high-resolution scan of the hyoid and larynx (CT_L) was acquired. Tube voltage was 120kV with a reference tube current of 300mAs (CT_N) and 350 mAs (CT_L). CT_N was reconstructed with standard reformations of the neck in axial, coronal, and sagittal orientations (3 mm slice thickness, 2 mm increment). CT_L was reconstructed in anatomically oriented sections (1 mm slice thickness, 1 mm increment). Image reporting was performed independently for standard reconstructions (CT_N) and additionally for isolated reimaging of laryngeal structures (CT_L). Macroscopic correlation by autopsy report was available for all cases. Fracture location was recorded in a binary fashion for all anatomic laryngeal regions.
Results: A total of 140 anatomical regions were compared per group. Sensitivity of fracture detection from CT_N was 45%, which was significantly increased on CT_L scans to 82% ($p<0.001$). Specificity was comparable between methods (CT_N: .97, CT_L: 0.96; $p=0.920$). Youden-index was improved from 0.43 to 0.78 in CT_L ($p<0.001$).
Conclusion: Post-mortem CT imaging provides an adequate detection rate with dedicated high-resolution acquisition and reconstruction protocol but is not adequate for fracture detection with standard parameters of clinical cervical protocol. A dedicated high-resolution CT of the larynx and hyoid should be used to guide autopsy.
Limitations: Results should be confirmed in a larger cohort.
Ethics committee approval: Ethics approval was granted, informed consent was waived.
Funding: No funding was received for this work.

Clinical assessment of metal artefact reduction methods in dual-energy CT in head and neck CT examinations

L. Xing*; ZhengZhou/CN (chenwan@hnair.com)*

Purpose: To determine the effect of iterative metal artefact reduction (iMAR) technique in reducing dental metallic artefacts in head and neck CT examinations.
Methods and materials: 30 patients with dental prosthesis implants were prospectively collected and the original data was reconstructed respectively in an iMAR group (Group A) and a conventional iterative reconstruction group (Group B). The CT and SD values of the two groups of images were measured respectively. The difference between the two groups was compared by a paired t-test.
Results: There was no significant difference in CT values on the opposite side of the same layer without artefacts ($P>0.05$). The CT values in Group A were significantly reduced in the high-density artefact area ($p<0.05$), while significantly increased in the low-density artefact area ($p<0.05$), and were closer to the CT values in the corresponding anatomical areas at the opposite side of the same layer. In terms of image noise, SD values in each measurement area of group A's images were lower than those of group B and significantly lower in high-density and low-density areas ($p<0.05$). In terms of subjective score, the results of the two groups of image evaluation are excellently consistent (Kappa=0.945, $p<0.05$). The subjective score of group A was significantly higher than that of the control group (group A:4.23±0.32, group B:2.11±0.51; $P<0.05$).
Conclusion: IMAR technique can significantly reduce metal artefacts around dental implants, correct CT values of surrounding tissues, help to accurately observe tissue structures around implants, and improve image quality, which has great clinical application value.
Limitations: The sample size is small and the results may be biased when the sample size is large.
Ethics committee approval: n/a
Funding: No funding was received for this work.

Dual-layer CT-derived 3-dimensional iodine quantification for inherent iodine of thyroid parenchyma: clinico-pathologic correlation and phantom validation

Y. H. Lee*; Ansan-Si/KR*

Purpose: The thyroid gland, as an inherently iodine-rich organ, shows uniquely higher attenuation in contrast to other neck structures on pre-contrast CT images. However, its attenuation varies among different thyroid disorders. We correlated iodine concentration (IC, mgI/ml) of thyroid parenchyma derived from

dual-energy CT (DECT) datasets with hormonal status and pathologic results with phantom validation.
Methods and materials: We retrospectively enrolled 227 patients (M:F=70:157, age= 47.9±10.6Yr) who consecutively underwent both US and neck CT examination before thyroid surgery during the past two years. On the additional iodine map from pre-contrast images obtained by dual-layer detector DECT scanner (120kVp), 3-dimensional IC measurement was done at the thyroid parenchyma sonographically devoid of nodules. After that, we statistically determined the mean IC of thyroid parenchyma depending on the thyroid hormonal status and pathologic results. A gammex phantom containing 7 iodine chambers with different IC ranging from 2 to 20mgI/ml was used to validate the accuracy of our scan parameters to calculate IC.
Results: Among the 165 euthyroid patients, the mean parenchymal IC was significantly lower in patients with pathologically proven Hashimoto's thyroiditis than those devoid of thyroiditis (0.95±0.49 vs 1.44±0.50, p<0.01). In the other 56 hyper-/hypothyroidism patients, the mean parenchymal IC was 0.35±0.59. From the phantom study for IC quantification, measurement error ranged from -0.2% to 2.0% with our DECT protocols.
Conclusion: DECT iodine quantification for inherent iodine could be helpful to understand thyroid parenchymal disorders.
Limitations: Limited to the specific technical parameters, for example, type of DECT or scanning condition.
Ethics committee approval: IRB-approved study.

RPS 1808-13 11:42
Evaluation of the role of dual-energy computed tomography (DECT) in thyroid nodules
S. Sagar, A. Kumar, N. Khandelwal, N. Panda, P. Dey, U. Nahar*; Chandigarh/IN*

Purpose: To assess the role of DECT in differentiating benign from malignant thyroid disease (BTD vs MTD).
Methods and materials: A prospective study was done between October 2017-October 2018 in our tertiary centre. DECT was performed using a 128-slice dual-source scanner (Siemens Somatom Definition Flash) for indications including staging, loco-regional extent, nodal status, and metastatic workup. Non-contrast (NC) and post-contrast (PC) sequences were evaluated for nodule size, attenuation value (A_v), and iodine concentration (I_c). FNA/histopathology was used as a gold standard.
Results: A total of 30 patients (21 females) having a mean age of 47.4 years were included. 15 patients had BTD and 15 patients had MTD including papillary carcinoma (n=9, 60%) and non-papillary malignancies (n=6, 40%). Benign nodules were larger than malignant nodules (mean size 42.9 vs 24.7mm respectively, p=0.013). MTD had higher PC A_v (mean HU 116.4) than BTD (82.6), while they had lower NC A_v (48.7 vs 62.1, p=0.006). MTD had higher PC I_c than BTD (2.83 mg/ml vs 1.32 mg/ml, p=0.001). The difference between PC I_c and NC I_c was defined as ΔI_c and that between PC A_v and NC A_v was defined as ΔAv. MTD had higher ΔI_c and ΔA_v than BTD (2.45mg/ml vs 0.93mg/ml, p=0.001 and 67.7 vs 20.5, p=0.002). PC A_v cut-off of 99.5 HU had 80.0% sensitivity and 86.7% specificity for identifying MTD (AUC 0.80). ΔI_c and ΔA_v cut-off of 1.12mg/ml and 36.7 had a sensitivity of 86.7% and 80.0% and a specificity of 86.7% and 86.7% (AUC 0.86 and 0.84, respectively).
Conclusion: DECT helps differentiate benign and malignant thyroid disease with a high sensitivity and specificity.

Can morphological analysis be useful for the detection and characterisation of adenomas in parathyroid MRI?
C. Z. Karaman, V. S. Öztürk, O. Abdullayev*; Aydin/TR (md.suhaozturk@gmail.com)*

Purpose: To review the preoperative MRI of patients with primary hyperparathyroidism who underwent surgery for parathyroid adenoma (PtA) and to investigate the morphological features that help differential diagnosis.
Methods and materials: Parathyroid MRIs of 184 patients from 2015-2018 were reviewed. Only 69 patients were operated on. 5 patients were excluded and 5 patients had bilateral lesions. In summary, 69 lesions from a total of 64 patients were analysed. Axial, sagittal, and coronal fat-saturated T2W TSE and axial pre/post-contrast T1W TSE sequences were obtained in a 1.5T MR system. T2W hyperintensity, oblonged morphology, "reverse-D" appearance, strong enhancement, and the extension to paraesophageal region were investigated. Sensitivity, specificity, and positive and negative predictive value were calculated for each finding (p<0.05).
Results: 56 were classified as parathyroid adenoma and 8 as non-PtA, pathologically. MR was negative in 5 lesions. The mean lesion size was 15 mm (4-44.8 mm). Of the 56 adenomas, 51 were T2A hyperintense while 38 showed strong enhancement. Oblonged morphology was present in 40 adenomas, "reverse D" appearance in 36, and paraesophageal extension in 16 adenomas. None of non-PtA lesions showed extension. There was a statistical significance for the strong enhancement (p=0.019) and sensitivity, specificity, and accuracy values were 70%, 75%, and 71%, respectively. The “reverse D” appearance described for the first time in the literature has been shown to be a common finding in adenomas and sensitivity, specificity, and accuracy values were 64%, 63%, and 64%, respectively.
Conclusion: Images on the sagittal plane may contribute to a morphological analysis for PtA in parathyroid MRI and oblonged morphology with reverse D appearance may facilitate the diagnosis.
Limitations: The number of non-adenoma lesions was little.
Ethics committee approval: Ethics committee approved.
Funding: No funding was received for this work.

Advanced visualisation of peroneal artery perforators prior to autologous transplantation in head and neck surgery by dual-energy CTA and semiautomatic vessel unfolding
M. Wiesmüller, W. Wuest, R. Heiss, C. Treutlein, M. Uder, M. S. May*; Erlangen/DE (marco.wiesmueller@uk-erlangen.de)*

Purpose: Visualisation of peroneal vessels prior to autologous transplantation of osteomyocutaneous fibular flap for mandibular reconstruction is essential for surgical success. Our aim was to improve and simplify the pre-surgical diagnostics of peroneal perforators using a dedicated dual-energy CTA protocol and semiautomatic vessel unfolding algorithm.
Methods and materials: CTA of the lower limbs was performed in 20 patients using dual-energy acquisitions from a third-generation dual-source CT and a high iodine flux (7mL/s, 350 mg/mL). Monoenergetic reconstructions (40 keV) were automatically reconstructed from the scanner and used for the semiautomatic centreline labelling of the peroneal arteries and their lateral perforators on a post-processing console using a dedicated vascular workflow. Curved MIP reconstruction was regarded as a gold standard. Vessel unfolding reconstruction was performed using a prototype software application. Number and length of perforator arteries were compared between curved MIP reconstruction, thin slice MIP in coronal orientation, posterior VRT, and coronal vessel unfolding of each lower limb.
Results: The vessel unfolding algorithm was applicable in all patients and significantly more perforator arteries could be detected compared to thin slice MIP and VRT reconstructions. The mean perforator length was only 7% shorter than in the gold standard, whereas values from thin slice MIP and VRT were significantly shorter. Bone superposition was less frequent in vessel unfolding compared to thin slice MIP.
Conclusion: The combination of low monoenergetic reconstructions and vessel unfolding allows for a comprehensive and precise presentation of small peroneal perforator vessels prior to autologous transplantation.
Limitations: A limited number of patients in this preliminary study.

Abbreviated MRI for HCC screening: a comparison of non-contrast, dynamic contrast-enhanced, and hepatobiliary phase sets

N. Vietti Violi[1], S. Lewis[2], J. Liao[2], M. Hulkower[2], G. Hernandez Meza[2], J. S. Babb[2], S. Kihira[2], K. Sigel[2], B. Taouli[2]; [1]Lausanne/CH, [2]New York, NY/US (nviettivioli@gmail.com)

Purpose: To compare the diagnostic performance and cost-effectiveness of AMRI sets extracted from a complete gadoxetic acid-enhanced MRI for HCC screening in a high-risk population.
Methods and materials: This retrospective study included 237 consecutive patients (M/F: 146/91, mean age: 58y) with chronic liver disease who underwent gadoxetic acid-enhanced MRI for HCC screening in 2017. Two radiologists independently reviewed 3 AMRI sets extracted from the complete exam: non-contrast [NC-AMRI: T2-weighted imaging (wi)+diffusion-weighted imaging (DWI)], dynamic-AMRI (Dyn-AMRI: T2wi+DWI+dynamic T1wi), and HBP-AMRI [T2wi+DWI+T1wi obtained during the hepatobiliary phase (HBP)]. Each patient was classified as HCC-positive or HCC-negative. The reference standard combined all available patient data. Estimated set characteristics, including historical US data, were incorporated into a cost-effectiveness analysis.
Results: The reference standard identified 13/237 patients with HCC (prevalence 5.5%, size 33.7±30 mm). The pooled sensitivities were 61.5% for NC-AMRI (95% confidence intervals: 34.4-83%), 84.6% for Dyn-AMRI (60.8-95.1%), and 80.8% for HBP-AMRI (53.6-93.9%), without significant difference between sets (p-range: 0.06-0.16). The pooled specificities were 95.5% (92.4-97.4%), 99.8% (98.4-100%), and 94.9% (91.6-96.9%), respectively, with a significant difference between Dyn-AMRI and the other sets (p<0.01). All AMRI methods were effective compared to US, with a life-year gain of 3-12 months compared to US against incremental costs of $11,494-$11,823.
Conclusion: NC-AMRI has limited the sensitivity for HCC detection, while HBP-AMRI and Dyn-AMRI showed excellent sensitivity and specificity, the latter being slightly higher for Dyn-AMRI. Initial cost-effectiveness estimates showed that all AMRI models are effective compared to US.
Limitations: Dyn-AMRI assessed using gadoxetic acid.
Ethics committee approval: The institutional review board approved the study and waived informed consent.

The predictive value of the liver imaging reporting and data system with contrast-enhanced ultrasound (v2017) in the risk of hepatocellular carcinoma in a high-risk population

J. Ding, L. Long, H. Zhou, Y. Zhou, Y. Wang, X. Jing; *Tianjin/CN*

Purpose: To explore the clinical value of the liver imaging reporting and data system (LI-RADS) version 2017 with contrast-enhanced ultrasound (CEUS) for the risk prediction of hepatocellular carcinoma (HCC).
Methods and materials: 571 patients with HCC risk factors received CEUS examination in our centre. 270 patients with 395 nodules were enrolled in this study according to the inclusion criteria. The final diagnostic reference standard was decided by surgical pathology or ultrasound-guided biopsy pathology. Each nodule was classified according to CEUS LI-RADS v2017. The diagnostic accuracy of the projections of CEUS LI-RADS v2017 for HCC was analysed retrospectively.
Results: 270 patients with 295 nodules included 245 HCCs, 13 intrahepatic cholangiocarcinomas (ICC), 8 combined hepatocellular cholangiocarcinomas (CHC), 2 metastatic neoplasms of other cellular origins, and 27 benign nodules. The numbers of LR-3, LR-4, LR-5, and LR-M categories were 16 (5.4%), 28 (9.5%), 183 (62.0%), and 68 (23.1%), and the positive predictive value (PPV) of LR-3, LR-4, and LR-5 was 43.8%, 60.7%, 98.4% for HCC, respectively. The sensitivity, specificity, and positive predictive value of the LR-5 category for HCC were 73.5%, 94.0%, and 98.4%.
Conclusion: CEUS LI-RADS v2017 classification standard has reliable risk prediction value for patients with high-risk factors of HCC, which the LR-5 category has a higher positive predictive value for patients at risk of HCC. However, the differential diagnosis between HCC and other non-HCC malignancies still remains to be further studied for LR-M observations.
Limitations: Due to the nature of the retrospective study, LR-1 and LR-2 categories nodules were not pathologically diagnosed and were not included in this study.
Due to pathological reasons, the proportion of LR-3 category nodules in this study is relatively small, which may lead to selection bias.

Direct-acting antiviral agents in HCV patients and risk of occurrence and recurrence of HCC: is it still a clinical dilemma?

F. Vernuccio, R. Cannella, S. Greco, G. Cabibbo, V. Di Marco, C. Cammà, M. Midiri, G. Brancatelli; *Palermo/IT (federicavernuccio@gmail.com)*

Purpose: To evaluate the intra-individual rate of occurrence and recurrence of hepatocellular carcinoma (HCC) in patients with hepatitis C virus (HCV) after sustained virologic response to direct-acting antivirals (DAA).
Methods and materials: We retrospectively included consecutive HCV patients with sustained virologic response to DAA from 2015-2019 imaged with CT or MRI. We excluded patients lacking pre-DAA and post-DAA imaging follow-up. A combined reference standard (imaging and pathology) was used for HCC diagnosis. Two radiologists reviewed imaging studies, categorised each lesion, and assessed treatment response according to LI-RADS v2018. Intra-individual differences in HCC occurrence and recurrence were evaluated with the McNemar test. The incidence rate of HCC after DAA therapy was calculated.
Results: The final cohort included 65 patients (mean age: 70±10 years old). Overall, pre-DAA and post-DAA mean follow-ups were 47±26 months, 25±25 months, and 24±15 months, respectively (pre-DAA vs post-DAA: p=0.472). HCC occurrence was demonstrated in a significantly larger number of patients before DAA than after DAA (n=48 (73.8%) vs n=25 (38.5%), respectively; p=0.002). After DAA, HCC occurred with a mean interval of 18±16 months and 60% (n=15) of HCC occurred after one year. Conversely, HCC recurrence was similar before and after DAA (n=5 (7.7%) vs n=12 (18.5%), respectively; p=0.092).
Conclusion: HCC occurrence is significantly reduced in patients with a sustained virologic response to DAA. Conversely, HCC recurrence is not significantly affected by DAA.
Limitations: The retrospective study design, small sample, and lack of cohort of HCV patients not treated with DAA.
Ethics committee approval: IRB-approved. Informed consent was waived.
Funding: No funding was received for this study.

Subcentimeter hepatocellular carcinoma in treatment-naïve patients: non-invasive diagnostic criteria and tumour staging on gadoxetic acid-enhanced MRI

M.-S. Park[1], S. H. Hwang[1], S. Park[2], S. Y. Kim[1]; [1]Seoul/KR, [2]Goyang-si, Gyeonggi-do/KR (radpms@yuhs.ac)

Purpose: To define the optimal non-invasive diagnostic criteria of subcentimeter hepatocellular carcinomas (HCC) and to evaluate the effect on tumour staging in treatment-naïve patients.
Methods and materials: This study included 110 treatment-naïve patients at risk of HCC eligible for curative treatment who had subcentimeter lesions

(n=136) on gadoxetic acid-enhanced magnetic resonance imaging (MRI). New diagnostic criteria for subcentimeter HCC was developed using logistic regression analysis. Subgroup analysis was performed for patients with co-existing HCC ≥1 cm (Co-HCC). The accuracy of MR staging with and without using the new criteria was compared by a generalised estimating equation test using pathologic staging as reference standards.
Results: 19.1% (26/136) of subcentimeter lesions were HCCs. 50% of subcentimeter lesions found in patients with co-HCCs were HCC, whereas 5.9% of them without co-HCCs were HCC (p=0.001). The presence of co-HCC, arterial phase hyperenhancement (APHE), and hypointensity on transitional phase (TP) were independent factors for diagnosing subcentimeter HCC. Compared with APHE and the hypointensity on portal venous phase (PVP), the new criteria (co-HCC, APHE, and hypointensity on TP) tended to show a higher sensitivity (46.2% vs 61.5%, p=0.185) and specificity (97.3% vs. 98.2%, p = 0.563). In patients with co-HCC, the new criteria outperformed APHE and hypointensity on PVP in terms of sensitivity (40.9% vs 72.7%, p=0.001) with comparable specificity (96.3% vs 92.6%, p=0.308). Including subcentimeter HCCs improved the accuracy of MR staging from 84.5% to 94.5% (p=0.001).
Conclusion: In patients with co-HCC, subcentimeter HCC can be accurately diagnosed when a lesion shows APHE and hypointensity on TP on gadoxetic acid-enhanced MRI. Our new criteria can improve the accuracy of tumour staging in treatment-naïve patients at risk of HCC.

Does LI-RADS v2018 add significant diagnostic value over LI-RADS v2017 in the categorisation of hepatic observation?

M. A. A. Basha[1], S. Abdelaziz Aly[2]; [1]Zagazig, AL/EG, [2]Benha/EG (Mohammad_basha76@yahoo.com)

Purpose: To investigate the added value of LI-RADS v2018 over LI-RADS v2017 in the categorisation of hepatic observation.
Methods and materials: In this prospective study, 211 patients with 268 liver observations detected during US surveillance underwent hepatic CT and MRI examinations, histopathology, and clinical and radiological follow-up. Two radiologists evaluated the observations and independently assigned an LI-RADS category to each observation based on LI-RADS v2017 and LI-RADS v2018. We evaluated the inter-reader agreement (IRA) with Kappa statistics and compared the diagnostic performance of LI-RADS v2018 and LI-RADS v2017 by Fisher's exact test using histopathology as the reference standard.
Results: LI-RADS v2018 yielded a better accuracy, sensitivity, and specificity for the categorisation of hepatic observation than LI-RADS v2017 (94.3 vs 91.8, 93.4 vs 90.8, 93.5 vs 91.2, respectively). There was no significant difference between using LI-RADS v2018 and LI-RADS v2017 in the categorisation of hepatic observation (p=0.23). The IRA of the LI-RADS scores among LI-RADS v2018 and LI-RADS v2017 was excellent (κ=0.9524).
Conclusion: Although LI-RADS v2018 improved the diagnostic performance of LI-RADS in the categorisation of hepatic observation, there was no significant difference between using LI-RADS v2018 and LI-RADS v2017.
Limitations: All MRI examinations were performed with an extracellular gadolinium contrast agent. We did not include contrast-enhanced US. We only considered untreated observations.
Ethics committee approval: Institutional review board approval was obtained. Written informed consent was obtained from all patients.
Funding: No funding was received for this work.

The prognostic value of LI-RADS classification in patient candidates for orthotopic liver transplantation

I. Vicentin[1], A. Coppola[2], G. Platania[3], D. Volterra[1], D. Ricci[1], M. Pecorilla[1], C. Sgrazzutti[1], A. Vanzulli[4]; [1]Milan/IT, [2]Cava De' Tirreni/IT, [3]Gravina Di Catania/IT, [4]Segrate/IT (vicentin.ilaria@gmail.com)

Purpose: To evaluate the prognostic value of LI-RADS classification of liver nodules in cirrhotic patients assessed before orthotopic liver transplantation (OLT) in predicting HCC-specific survival.
Methods and materials: We considered 245 patients who underwent OLT from 2005-2015 at our institute with CT or MRI available both at the time of insertion in the transplant list and within 4 months before OLT. CT and MRI exams were read by 2 radiologists in consensus. Liver nodules were classified into 7 categories according to the LI-RADS classification: LR-3, LR-4, LR-5, LR-M, LR-TIV, LR-TR viable, and LR-TR not viable; we excluded patients in whom it was not possible to assign a category (LR-NC) and nodules with LR-TR equivocal. To predict HCC-specific survival, we used Metroticket2calculator, which considers the number of nodules, size of the largest nodule, and α-fetoprotein value. We considered LR-5+LR-TR viable+LR-TIV nodules, then we included LR-4 nodules, and finally, we added LR-3 nodules. We used the c-index to assess prognostic accuracy in survival prediction. We compared c-indexes from the 3 models based on LI-RADS with a c-index obtained by calculating the number and maximum size of nodules obtained from a multidisciplinary tumour board meeting (MDTB).
Results: 555 nodules were categorised: 111 LR-3, 54 LR-4, 175 LR-5, 1 LR-TIV, 1 LR-M, 63 LR-TR viable, and 150 LR-TR not viable. The c-index calculated by applying MetroTicket parameters was 0.6 when considering LR-5+LR-TIV+LR-TR nodules, 0.6 when also including LR-4 nodules, and 0.65 when including LR-3 nodules.The c-index calculated by applying Metroticket parameters obtained from from MDTB was 0.72.
Conclusion: The best prognostic value based on the Metroticket 2.0 algorithm is obtained by considering the number and size of liver nodules obtained from MDTB. The LI-RADS classification showed similar prognostic value (P>0.05) only when including a low (LR-3), intermediate (LR-4), and high probability (LR-5) of malignancy nodules.
Limitations: A retrospective study.

Contrast-enhanced ultrasound adds value to the differentiation of hepatic neuroendocrine neoplasms from hepatocellular carcinomas

J. Huang, X. Xie; Guangzhou/CN (hjingzhi@mail2.sysu.edu.cn)

Purpose: The liver is the most common metastatic site for neuroendocrine neoplasms. Ultrasonography is widely used to detect focal liver lesions, but it is difficult to characterise hepatic neuroendocrine neoplasms (hNEN) from hepatocellular carcinomas (HCC). We investigated the value of contrast-enhanced ultrasound (CEUS) to distinguish hNEN from HCC in non-cirrhotic liver parenchyma.
Methods and materials: From January 2014-June 2019, 92 patients who underwent liver CEUS examinations followed by a pathological diagnosis of neuroendocrine neoplasms in our institution were retrospectively evaluated in the study. At the same time, 92 patients with histologically-proven HCC without liver cirrhosis were randomly selected from the database as a control group. For each lesion, conventional ultrasound features and CEUS parameters, including enhancement pattern and washout time, were evaluated. In addition, the diagnostic accuracy of ultrasonic parameters for the differentiation of hNENs and HCCs was assessed using a receiver operating characteristics (ROC) curve analysis.
Results: hNEN and HCC showed significant differences in the number of nodules (P<0.001), enhancement level in portal phase (P<0.001), and the start of contrast washout time (P<0.001). Compared with HCCs, hNENs more often showed multiple lesions, less likely demonstrated iso-enhancement in the portal phase, and a quicker start of the contrast washout. When using the number of nodules and washout time on CEUS as the differential diagnosis of hNEN and HCC, the area under the ROC curve was 0.934 (p<0.001, 95% CI=0.897-0.972) with 75.0% sensitivity, 75.6% specificity, and 84.8% accuracy.
Conclusion: Contrast-enhanced ultrasound improves the differentiation of hNEN and HCC in non-cirrhotic livers, with a combination of the number of nodules and washout time on CEUS showing the strongest diagnostic performance.
Limitations: A single-centre and retrospective-designed study.
Ethics committee approval: n/a

The development and validation of a radiomics nomogram for predicting transcatheter arterial chemoembolisation refractoriness of hepatocellular carcinoma

J. S. Kim, H. Sheen, J. K. Lee, S. Y. Baek*; Seoul/KR (truth0508@nate.com)*

Purpose: To develop and validate a radiomics nomogram for the pretreatment prediction of transcatheter arterial chemoembolisation (TACE) refractoriness with pre-therapeutic dynamic CT in patients with hepatocellular carcinoma without metastasis.
Methods and materials: This study included 80 patients with HCC treated with TACE, except for any vascular involvement, from July 2016-November 2018, after exclusion. The datasets were split into a training set (80%) and a test set (20%) for feature selection and we did 10-fold cross-validation. 40 radiomic features were extracted from arterial-phase CT using LIFEx. A lasso regression model was used for radiomics signature selection and the selected signatures were validated using a Mann-Whitney U test. The radiomics nomogram was based on the multivariate logistic regression model incorporated the rad score (radiomics score), CT image factors (enhancement, homogeneous arterial, heterogeneous portal, capsule, Bilobar, and multiple), and clinical factors (age, sex, and logAFP). For optimising the radiomics nomogram, multiple backward stepwise elimination methods were investigated. We also evaluated the radiomics nomogram using ROC and a confusion matrix. All statistical analyses were performed using RStudio software.
Results: The rad score, which consisted of GLZLM (grey-level zone length matrix), LZLGE (long-zone low grey-level emphasis), and GLZLM-GLNU (grey-level nonuniformity), was significantly associated with TACE refractioness ($p<0.05$) and a higher odds ratio (≥1.0). Predictors contained in the individualised prediction nomogram included rad score and Biolbar. The radiomics nomogram showed a good predicting performance: 0.91 AUC, 0.75 sensitivity, 0.91 specificity, 0.75 precision, and 0.87 accuracy.
Conclusion: This study presents a radiomics nomogram that incorporates the rad score and CT image factor (Biolbar), which can be conveniently used to facilitate the pretreatment prediction of TACE refractoriness.
Limitations: A retrospective study.
Ethics committee approval: Informed consent was waived due to the retrospective nature of the analyses.
Funding: No funding was recieved for this work.

Gadoxetic acid MRI for the assessment of HCC response to Yttrium 90 radioembolisation: correlation with histopathology

N. Vietti Violi[1], S. Hectors[2], J. Gnerre[2], A. Law[2], M. I. Fiel[2], B. Taouli[2];
[1]Lausanne/CH, [2]New York, NY/US (nviettivioli@gmail.com)

Purpose: To assess the diagnostic performance of gadoxetic acid MRI for evaluating the response of hepatocellular carcinoma (HCC) to Yttrium 90 transarterial radioembolisation (RE) using pathology as the reference standard.
Methods and materials: This retrospective study included 48 consecutive patients (M/F 36/12, mean age 62 y) with HCC treated by RE, followed by surgery (liver resection/transplantation:14/34), with MRI using gadoxetic acid within 90 days before surgery. Two independent radiologists evaluated the following criteria: the percentage of necrosis on subtraction images based on late arterial, portal venous and hepatobiliary (HBP) phases, modified (m)RECIST, LI-RADS, and apparent diffusion coefficient (ADC). Data was correlated to the percentage of necrosis on pathology. Inter-reader agreement for the radiologic percentage of necrosis was assessed using an interclass correlation coefficient (ICC). Receiver operating characteristic analyses were used to determine the prediction of complete pathologic necrosis (CPN). Correlation between radiologic and pathologic percentage of necrosis was assessed using Pearson's correlation.
Results: Histopathology demonstrated 71 HCCs (mean size: 2.8±1.7 cm), including 42 with CPN. There was an excellent inter-reader agreement for assessing the radiologic percentage of necrosis (ICC 0.82-0.89). The percentage of tumour necrosis, mRECIST, and LI-RADS were all significant ($p<0.0001$) predictors of CPN (AUC 0.80-0.82 for the radiologic percentage of necrosis and AUC 0.73-0.75 for mRECIST and LI-RADS), while ADC was not a significant predictor of CPN (AUC 0.63). The radiologic percentage of necrosis was significantly correlated to the histopathologic degree of tumour necrosis ($r=0.66-0.8$, $p<0.0001$).
Conclusion: Image subtraction has an excellent diagnostic performance for predicting CPN in HCC treated with RE; better than mRECIST, LI-RADS, and ADC.
Limitations: Few patients included: 42 patients/72 lesions.
Ethics committee approval: The institutional review board approved the study and waived informed consent.
Funding: Swiss National Science Foundation, fellowship P2LAP3_178053.

Advanced hepatocellular carcinoma treated with sorafenib: a prediction of overall survival using an integrated model based on pretreatment CT texture features and sarcopenia

T. Polidori, M. A. Tipaldi, D. Caruso, E. Ronconi, M. Zerunian, M. Rossi, A. Laghi*; Rome/IT (tiziano.polidori13@gmail.com)*

Purpose: To determine whether texture features on pretreatment contrast material–enhanced computed tomographic (CT) images combined with an analysis of sarcopenia can predict the overall survival (OS) in patients with advanced hepatocellular carcinoma (HCC) treated with sorafenib.
Methods and materials: We retrospectively evaluated 54 patients with advanced hepatocellular (HCC) treated with sorafenib from September 2008-August 2013. The inclusion criteria for this study were available pre-treatment computed tomography (CT) at the same hospital and available OS. 14 patients met these criteria and were enrolled in the study. CT texture and sarcopenia analysis were performed on pretreatment portal venous images. We analysed CT texture first level features (mean, standard deviation, entropy, mean of positive pixels, kurtosis, and skewness) at different anatomic scales ranging from fine to coarse texture. Sarcopenia was defined by a reduced skeletal muscle index calculated from an L3 section CT image. Statistical analysis was performed with SPSS 24.
Results: The normality distribution of continuous variables was assessed using a Shapiro-Wilk test and a univariate analysis was performed via the appropriate test (Chi-squared, Mann-Whitney U, and a 2-tail paired t-test) in order to identify variables which affected overall survival. Sarcopenia and 4 texture features were significant ($p<0.05$): mean, entropy, mpp, and skewness. These factors were combined to create a hybrid texture-clinical score, using coefficients derived from a multivariate Cox proportional-hazards regression model. The performance of the model was calculated using the Kaplan-Meier survival analysis (log rank=24.763, $p<0.001$).
Conclusion: Texture analysis combined to sarcopenia analysis can help predict overall survival in patients with advanced hepatocellular carcinoma (HCC) treated with sorafenib.
Limitations: The small population study.

Molecular imaging of tumour extracellular pH in a 3D organotypic in vitro model for liver cancer

I. Schobert[1], C. Hamm[1], L. Adam[1], J. Chapiro[2], J. Duncan[2], F. Hyder[2], D. Coman[2], L. J. Savic[1]; *[1]Berlin/DE, [2]New Haven, CT/US (isabel.schobert@charite.de)*

Purpose: To establish non-invasive magnetic resonance spectroscopy (MRS)-based imaging of extracellular pH (pH_e) for the monitoring of metabolic activity in a 3D organotypic in vitro model of liver cancer.
Methods and materials: Liver tumour cell lines with varying metastatic potential (VX2, HepG2, HuH7, and SNU475) and non-tumoural hepatocytes (THLE2) were cultured in monolayer and 3D collagen-I-based cell cultures to mimic an organotypic fibrotic liver tumour microenvironment. Non-invasive MRS-based pHe-mapping was employed on a 9.4T MR scanner using biosensor imaging of redundant deviation in shifts (BIRDS) in 3D cell cultures to compare metabolic activity among cell lines a) without treatment, b) supplemented with 25mmol/L

D-glucose, and c) treated with anti-glycolytic 3-bromopyruvate. Imaging findings were correlated with immunohistochemistry stainings indicative of tumour metabolism (GLUT-1) and acidity (LAMP-2).
Results: MRS-based pH_e-mapping revealed lower pH_e of VX2 (pH_e=6.7±0.03) and HuH7 (pH_e=6.79±0.05) compared to HepG2 (pH_e=6.91±0.12) and SNU475 (pH_e=6.93±0.03), while THLE2 hepatocytes showed physiologic liver pH_e (pH_e=7.1±0.02). Upregulation of GLUT-1 confirmed the hyperglycolytic phenotype of liver tumour cells. Incubation with 25mmol/L glucose significantly increased acidity in 3D cell cultures with VX2 (Δ0.28, p<0.001), HepG2 (Δ0.06, p<0.001), and HUH7 (Δ0.11, p<0.001), respectively. In turn, treatment with 3-bromopyruvate resulted in a gradual increase of pH_e in all cancer cell lines, where commonly used viability assays were insensitive to detect any therapy-induced effects.
Conclusion: As most liver tumours are hyperglycolytic, creating microenvironmental acidosis via excess lactate secretion, MRS-based pH_e-mapping revealed lower pH_e in cell lines with high metastatic potential. Therefore, this study introduces a translational model to image tumour-pH_e as a functional molecular biomarker for the metabolic phenotype, tumour aggressiveness, and potential use for testing of drug effects in vitro.
Limitations: The limited spatial resolution; no direct pH-measurement validation (31P-MRS was performed as validation).

A prospective study of 18F-FDG-PET/CT with integrated diagnostic multi-phasic contrast CT in the initial staging of hepatocellular carcinoma: the impact on staging systems

H. Abdelhalim[1], M. Houseni[2], M. Elsakhawy[2], N. Abd Elbary[2], O. Elabd[2];
[1]Shibin El Kom/EG, [2]Shebein ElKom/EG
(heba.abdelhalim@liver.menofia.edu.eg)

Purpose: To evaluate the role of fluorine 18-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG-PET/CT) with integrated multiphasic contrast CT in the staging of hepatocellular carcinoma (HCC) and its effect on the initial management plan.
Methods and materials: A prospective analysis included 100 patients (91 males and 9 females) suspected to have HCC and referred to our centre for staging and treatment. All patients underwent imaging by 18F-FDG-PET/CT with integrated multiphasic contrast CT. Imaging findings were interpreted separately and with after image fusion. BCLC stage and compliancy with Milan criteria were assessed. Results were compared to reference data detected by histopathology and/or follow-up 18-F-FDG PET/CT.
Results: 18F-FDG-PET/CT with integrated multiphasic contrast CT demonstrated higher sensitivity and specificity than separate CECT for the detection of primary HCC (93.4% and 58.3%), regional lymph nodal metastases (91.3% and 40.3%), and pulmonary deposits (88.2% and 95.2%). Regarding the BCLC staging system, 18F-FDG-PET/CT with integrated multiphasic contrast CT showed accurate HCC staging in 53 patients (53%) compared to only 44 patients (44%) for separate CECT. Regarding the Milan criteria, 18F-FDG-PET/CT with integrated multiphasic contrast CT was accurate in 65 cases (65%) compared to only 60 cases (60%) for separate CECT.
Conclusion: 18F-FDG-PET/CT with integrated multiphasic contrast CT improves the initial staging of HCC and can significantly change the initial management plan.
Limitations: Histopathologic confirmation of metastases was not possible in all cases.
The criteria we used to determine metastasis may have some underestimation, even though the study was prospective.

The role of portal vein thrombosis in the assessment of perfusion analysis during dynamic computed tomography in patients with advanced hepatocellular carcinomas

A. Pecorelli[1], D. Ippolito[1], C. Maino[1], G. Querques[1], C. Talei Franzesi[1], S. Sironi[2]; *[1]Monza/IT, [2]Bergamo/IT (pecorelli.anna@gmail.com)*

Purpose: To investigate whether portal vein thrombosis (PVT) influences perfusion computed tomography (pCT) analysis in patients with advanced hepatocellular carcinomas (HCC) treated with sorafenib.
Methods and materials: 106 pCT consecutively performed in 38 patients with advanced HCC were analysed. Patients were divided according to the presence or absence of PVT. pCT was based on the acquisition of 16 dynamic slices/scan per 40 scans, performed on a 256-slice MDCT scanner after i.v. bolus injection of 50 ml iodinated contrast agent (350 mgI/ml) at a flow rate of 5 ml/s. The following pCT parameters were calculated for both normal liver parenchyma and HCC: hepatic perfusion (HP, ml/s/100g), arterial perfusion (AP, ml/s), portal perfusion (PP, ml/s), and hepatic perfusion index (HPI, %). Continuous variables were expressed as mean and standard deviation.
Results: No statistically significant differences were found in HP, AP, PP, and HPI values of HCC lesions between patients with and without PVT. pCT analysis of normal liver parenchyma showed that HP was significantly higher in patients with PVT in comparison to those without (14.6±5.4 vs 18.1±11.3, p=0.002) while HPI was significantly lower (24.1± 28.1 vs 13.2± 13.2, p=0.002). No differences were found in AP and PP values.
Conclusion: The presence of PVT causes parenchyma perfusion changes related to the reduction of portal venous flood and the increase of arterial blood flow, however, these haemodynamic changes do not modify the perfusion analysis of HCC lesions due to the development of typical unpaired arteries that are not associated with portal vein branches. This behaviour also allows the performance of pCT analysis in patients with advanced HCC and PVT.
Limitations: A retrospective study.
Ethics committee approval: IRB approval was granted.
Funding: No funding was received for this work.

Virtual monoenergetic images from spectral detector CT (SDCT) facilitates washout assessment in arterially hyper-enhancing liver lesions

R. P. Reimer, N. Grosse Hokamp, A. Fehrmann Efferoth, A. Krauskopf, J. R. Kröger, T. Persigehl, D. Maintz, A. Bunck; *Cologne/DE*
(robert.reimer@uk-koeln.de)

Purpose: Recent studies have demonstrated that virtual monoenergetic images (VMIs) improve soft tissue contrast and conspicuity for hypodense liver lesions. This study investigates whether this translates into a benefit for washout assessment of arterially hyper-enhancing liver lesions in delayed-phase CT images.
Methods and materials: Our retrospective study was approved by the institutional review board. 60 arterially hyper-enhancing lesions in 30 patients (age: 65±9yrs, M/W: 20/10) were included. All patients underwent multi-phase contrast-enhanced SDCT (unenhanced, arterial, portal-venous, and delayed) for HCC work-up. MRI, CEUS, or biopsy within 3 months served as a standard of reference to determine the lesions as hepatocellular carcinomas (HCC) or non-HCCs. VMIs (40-200keV, 10keV-increment) and conventional images (CI) were reconstructed. Regions-of-interest were placed in lesions, liver parenchyma, and muscle on delayed phase; washout (HU_{liver}-HU_{lesion}) and the lesion-to-liver ratio (LLR) were calculated. Visual analysis was performed on 40, 60, 80keV, and CI by 3 radiologists. On a 5-point Likert scale, conspicuity and confidence of washout-evaluation were assessed. Statistical assessment was performed using ANOVA adjusted for multiple comparisons and a Wilcoxon test.
Results: The lesion size was 3.0±2.4 cm. Irrespective of reconstruction technique and keV-levels, washout and LLR were significantly higher on delayed phase images in HCC (n=50) compared to non-HCC lesions (n=10) (p<0.05). In HCC lesions, washout and LLR were significantly higher in VMIs with 40keV compared to CI and higher VMI keV-levels (p<0.05; e.g. washout in 40keV vs CI: 26.2±22.8 vs 11.8±8.5). Subjective analysis confirmed the best washout-evaluation (p<0.05) and confidence of evaluation in 40keV (p>0.05).
Conclusion: By increasing the lesion contrast, VMIs with low keV-values from SDCT, especially using 40keV, significantly improve the qualitative and quantitative assessment of washout in hyper-enhancing liver lesions.
Limitations: A retrospective, single-centre study.
Ethics committee approval: IRB-approval given.
Funding: No funding was received for this work.

Intravoxel incoherent motion diffusion-weighted imaging in the differentiation of solid hepatic lesions using a volumetric approach: new frontiers!
M. Puglia[1], M. A. Bali[2], S. Picchia[3], M. Orton[4], S. Doran[5], T. Feiweier[6], D.-M. Koh[4], G. Morana[7]; [1]Pozzuoli/IT, [2]Brussels/BE, [3]Latina/IT, [4]London/UK, [5]Sutton/UK, [6]Erlangen/DE, [7]Treviso/IT (martapuglia@alice.it)

Purpose: To analyse the valence of an IVIM model and ADC value for the characterisation of solid focal liver lesions (FLLs) using a volumetric approach in 4 groups: benign vs malignant, FNH vs adenoma, hypervascular benign vs hypervascular malignant, and hypervascular malignant vs hypervascular malignant.
Methods and materials: 100 patients with 104 FLLs (77 malignant-27 benign) underwent liver 1.5T MRI for routine examination sequences using IVIM diffusion-weighted imaging with 11 b-values (0-800 s/mm2). The apparent diffusion coefficient (ADC) and IVIM-derived parameters, such as pure diffusion coefficient (D), pseudo diffusion coefficient (Ds), perfusion fraction (f), and their product (fDs) were computed with a volumetric approach and compared with the groups. A ROC curve analysis was performed to assess their diagnostic value.
Results: ADC and D were significantly lower in the malignant group than in the benign group (ADC mean: 1.38±0.36 vs 1.60±0.58; D mean 0.88±0.29 vs 1.05±0.30) × 10-3 mm2/s, and in the hypervascular malignant than hypervascular benign (ADC mean 1.38±0.33 vs 1.60±0.72; D mean: 0.90±0.21 vs 1.05±0.29) × 10-3 mm2/s. Ds did not show statistical differences. FDs were significantly lower in the hypovascular malignant than in the hypervascular malignant group (mean 9.96±1.03 vs 12.7±8.5) × 10-3 mm2/s. F was also lower in the hypovascular malignant than in the hypervascular malignant group
Conclusion: Compared with ADC, the IVIM model values using a volumetric approach improves the characterisation of FLLs.
Limitations: A retrospective study and a selection bias could be possible. A larger patient cohort may be useful to validate our results.

Role of diffusion tensor imaging as a biomarker for cases with a history of optic neuritis in multiple sclerosis patients
M. A. S. M. Soliman; Cairo/EG (moataz_As20@hotmail.com)

Purpose: Using DTI for assessment of optic nerve integrity in MS patients with optic neuritis, and the possible affection of the contralateral optic nerve.
Methods and materials: Case-control cross-sectional observational study on 54 RRMS patients (17 males and 37 females; mean age: 31.35 ± 7.82 SD) according to Revised McDonald Criteria. Age and sex-matched healthy volunteers were recruited as control with a mean age of 29.54 ± 8.35 SD. Using 3 ROI for ON and one for chiasm. Comparing DTI results with previous OCT and optic nerve sheath diameter in patients records.
Results: 54 (40.3%) nerves affected and 54 non-affected optic nerves (40.3%) in the patient group and 26 (19.4%) normal control optic nerves. FA values in the proximal segment with a mean 0.52 + 0.04 SD among the control group. And 0.27 + 0.05 SD, 0.27 + 0.04 SD in affected and nonaffected eyes of patients respectively. There was a significant statistical difference between the patient and control groups for all four FA values ($p < 0.001$). No statistically significant difference between the FA values obtained from the affected and un-affected optic nerves within the patient group with a P-value of 0.1.
Conclusion: Quantitative DTI FA values were able to detect axonal loss in MS-related optic neuritis, with a similar degree of axonal loss in the contra lateral healthy optic nerve so it can be used for assessment of optic nerve integrity and response to therapy.
Limitations: Six months drop period between OCT and MRI data aquisition. Poor assessment of optic nerve at the orbit apex.
Ethics committee approval: n/a

A prospective study to evaluate the role of MRI with MR spectroscopy of ring-enhancing lesions in the brain
S. S. Tonpe; Secunderabad/IN (sudhanshutonpe@gmail.com)

Purpose: To differentiate neoplastic from non-neoplastic brain lesions using conventional and advanced MR imaging techniques.
Methods and materials: Contrast MRI and MRS were done on 50 patients with GE Optima 1.5 Tesla MRI-machine referred with clinically suspected space-occupying lesions (SOL) and patients with incidental/diagnosed ring-enhancing lesion by CT scan were enrolled in the study from June-18 to June-19. The data will be entered in MS EXCEL spreadsheet and analysis will be done using Statistical Package for Social Sciences (SPSS) VERSION 22.0.
Results: Out of 50 cases, 22 are tuberculomas, 16 are NCC, 5 are abscess, 5 metastasis, 1 case of pilocytic astrocytoma and 1 tumefactive demyelination. Males were predominantly affected (31 cases - 62% of the cases) than females (19 cases - 38 %). 21-30 years is the most common age group involved (28% of the cases) and seizures are the most common presenting complaint (84%). The single lesion was noted in 34 % of patients whereas the rest 66% presented with multiple cases. Follow-up CT/MRI in 26 patients show resolution of the lesion and its associated perilesional oedema.
Conclusion: MRI is non-invasive and non-radiating is an ideal imaging modality. MRS helps in the characterisation of various ring-enhancing lesions.
Limitations: MRS could not be performed in four cases due to the presence of lesion close to the bone. MRS helps in the characterisation of various ring-enhancing lesions. However, no lesion can be diagnosed based on the findings of MRS as the sole criteria.
Ethics committee approval: After obtaining a written informed consent the patient was evaluated with Contrast MRI and MRS. The gold standard for diagnosis of brain mass is biopsy with histopathologic evaluation; however, most of the patients were followed up to correlate the findings with clinical imaging follow-up.
Funding: No funding was received for this work.

Genetic and environmental effects on the morphology and haemodynamics of the Circle of Willis: cross-sectional magnetic resonance angiography and transcranial ultrasound twin studies
B. Forgo[1], D. L. Tarnoki[1], T. Horváth[1], E. Medda[2], C. Baracchini[3], A. Sas[4], C. Oláh[4], L. Kostyal[5], A. Tarnoki[1]; [1]Budapest/HU, [2]Rome/IT, [3]Padua/IT, [4]Miskolc/HU, [5]Malyi/HU (fbia021@gmail.com)

Purpose: Increasing evidence supports that Circle of Willis (CoW) variants predispose to cerebrovascular ischaemia. However, results on the factors determining CoW variants are sparse and conflicting. We aimed to determine whether CoW morphology and haemodynamics are associated with genetic or environmental factors in twins.
Methods and materials: We investigated two separate twin populations: 1) 120 volunteer members of the Hungarian Twin Registry underwent time-of-flight magnetic resonance angiography (TOF-MRA) to record hypoplasia/aplasia in each CoW artery. 2) 64 volunteer members of the Italian Twin Registry were examined by transcranial colour-coded duplex sonography to investigate CoW haemodynamics. Concordance rates of CoW variants and raw heritability of haemodynamic traits were calculated. Cardiovascular risk factors were

compared within twin pairs discordant for CoW morphology using paired t-test and Fisher's exact test.
Results: The average age was 52±21 and 43±23 years in the first and second twin group, respectively. Concordance rates were higher in dizygotic than in monozygotic twins regarding anterior (0.47 and 0.22, respectively) and posterior (0.85 and 0.69, respectively) CoW variants. Cardiovascular risk factors did not differ significantly within monozygotic twin pairs discordant for CoW morphology ($p>0.05$ for body-mass index, hypertension, hypercholesterolemia and smoking, respectively). Raw heritability of CoW haemodynamics was low to moderate (0.00-0.56).
Conclusion: Our results support the dominance of environmental factors on both morphology and haemodynamics of the CoW. However, no cardiovascular risk factor was identified as a predictor of CoW variants. Consequently, our results stimulate further research aiming at specifying the environmental factors affecting CoW morphology.
Limitations: Major limitations include small sample size, and low spatial resolution and flow-dependence of TOF-MRA.
Ethics committee approval: The regional ethical committees approved the study (approval number: 1046-260/2014; 189/2014, 2014/10/21). All participants signed informed consent.
Funding: No funding was received for this work.

Discrimination of intracranial ring-enhancing lesions using diffusion-weighted imaging, MR spectroscopy and diffusion tensor imaging
M. S. A. Faragalla*; Mansoura/EG (msaadfarag@gmail.com)*

Purpose: To differentiate intracranial ring-enhancing lesions using DWI, DTI and MRS.
Methods and materials: Forty-six patients examined by (1) DWI: mean ADC value, (2) MRS: calculated Cho/Cr ratio, (3) DTI: mean fraction anisotropy.
Results: Mean ADC values in the cystic part showed no significant difference between the primary tumours and secondary tumours (P-value = 0.07), while mean ADC value measured in the centre of abscess shows a significant difference from tumours (P= 0.002). No statistically significant difference between the ADC values measured in the enhancing wall of the primary tumours, secondary tumour and abscess; (P= 0.09).While mean ADC values measured in peritumuoral oedema could differentiate tumour infiltration from vasogenic oedema show a slightly significant difference with (P-value = 0.04). In MR Spectroscopy, the mean Cho/Cr ratio of tumours (4.2 ± 1.23) was significantly higher than abscess (1.65 ± 0.45) (P=0.006). And it's also noted that the mean value of the intralesional Cho/Cr ratio of tumour recurrence groups were significantly higher than radiation necrosis group (P-value =0.02). ROC curve analysis demonstrated a cut off value of 1.9. As regard DTI, the mean FA measured in peritumoural oedema surrounding the primary tumours demonstrates higher value than the FA measured in the peritumoural oedema of metastases, 0.235 and 0.147 respectively. ROC curve demonstrated cut-off value of 0.165.
Conclusion: DWI, MRS and DTI provided a greater confidence in differentiation of (primary from metastatic tumours), (tumours from abscesses) and (radiation necrosis from tumour recurrence).
Limitations: The studies measured ADC value from a single slice of ADC maps, which may cause observer bias. The study was performed on two MRI machines which may show slight differences and variability in results.
Ethics committee approval: Approved by Institutional Research Board, Mansoura University.
Funding: No funding was received for this work.

The influence of antiretroviral therapy on brain imaging in HIV infection
E. Bakulina, T. Trofimova*; St. Petersburg/RU (Bakulina26region@gmail.com)*

Purpose: To study the neuroimaging in HIV-infected patients with different levels of CD4 cells, plasma HIV RNA, ART status.
Methods and materials: The eligibility criteria: HIV+, performed brain MRI, an adult. Examination data of 410 patients included a history of HIV infection, opportunistic diseases, current CD4 count, plasma HIV RNA, pathogen identification in CSF. Statistic analysis included chi-square (with Yates correction), Fisher's, the Mann-Whitney, Wald criteria.
Results: Regular ART was associated with a lower incidence of: large asymmetric lesions, caudate nuclei involvement, perilesional oedema, ring contrast enhancement. Duration of ART for more than five years reduces the incidence of brain involvement in HIV, contrast enhancement, white matter lesions, the involvement of the frontal lobes and basal nuclei. Lower current CD4 cells were associated with large asymmetric lesions, the involvement of the basal ganglia and posterior fossa, perilesional oedema and mass effect, blooming artefact on T2*, ring and nodular contrast enhancement. Plasma HIV RNA above 50 copies/ml was associated with diffuse white matter lesions, large asymmetric lesions, the involvement of the cerebellum, perilesional oedema. In major cases of CNS-IRIS we observed acute inflammatory demyelination, which was characterised by the appearance of new focal lesions, as well as the increase of old ones, atypical patterns of contrast enhancement: perivascular, peripheral, nodular, leptomeningeal.
Conclusion: ART and dependent on its current CD4 cells, plasma HIV RNA had an influence on the severity of brain structural damage. With the disease progression, the most vulnerable regions were basal ganglia and cerebellum despite ART. The atypical PML were significantly more often visualised in CNS-IRIS.
Limitations: This study was limited by its retrospective design, qualitative neuroradiological criteria, and several data were incomplete.
Ethics committee approval: The study approved by the ethics committee in accordance with the criteria ICH GCP. All patients have signed informed consent.
Funding: No funding was received for this work.

MyT3 18-8 10:54
Comparison of 3D DIR, 3D FLAIR and 2D FLAIR pulse sequences for imaging in demyelinating disorder (in multiple sclerosis) at 3 Tesla
K. Nekar, P. P. Wali, R. Ananthasivan, U. Acharya*; Bangalore/IN (drkrishna3thi23@gmail.com)*

Purpose: Comparing 3D DIR sequence with that of 3D FLAIR and 2D FLAIR sequence in order to find out the h sensitivity in the detection of multiple sclerosis (MS) lesions and in addition we would like to further evaluate which among the 3D sequences would have higher sensitivity and specificity in picking up demyelinating lesions in the brain.
Methods and materials: Study population (minimum of 30 cases) will include patients who are being evaluated for demyelination disorders with MRI. Imaging was performed on a 3T Philips MR system using 3D DIR, 3D FLAIR sequences with the same parameters, including FOV, matrix, slice thickness, voxel size, and a number of signals averaging (NSA) in addition to routine T1, T2, diffusion-weighted and 2D FLAIR.
Results: Descriptive and inferential statistical analysis has been carried out in the present study. Results on continuous measurements are presented on mean ± SD (min-max) and results on categorical measurements are presented in number (%). Significance is assessed at 5 % level of significance. The following assumptions on data are made. Wilcoxon Signed rank test has been used to find the significance of the median score in two groups.
Conclusion: DIR brain imaging had the highest sensitivity in the detection of supratentorial lesions compared to3D FLAIR and 2D flair. In addition, the lesions obtained with 3D DIR images were more easily visualised.
Limitations: Patients with cardiac pacemakers and metallic implants will not be subjected to MRI. Motion disorder and claustrophobia, if severe, may make the examination difficult.
Ethics committee approval: The study is approved by a diplomate of the national board.
Funding: No funding was received for this work.

Therapy results of pericallosal aneurysms: a retrospective unicentre study
C. Deuschl[1], M. Darkwah Oppong[1], K. Wrede[1], A. Radbruch[2], M. Forsting[1], I. Wanke[1], C. Mönninghoff[1]; [1]Essen/DE, [2]Heidelberg/DE *(cornelius.deuschl@uk-essen.de)*

Purpose: This retrospective unicentre study aims to compare treatment results of ruptured and unruptured pericallosal artery aneurysms (PAAs) regarding

postprocedural complications, patient outcome and aneurysm recurrence after endovascular (EVT) and neurosurgical treatment (NT).
Methods and materials: A total of 67 patients with PAA were admitted to our hospital, 44 patients with subarachnoidal haemorrhage (SAH) due to a ruptured PAA and 23 patients with unruptured PAA. The radiographic features of PAA were collected from pretreatment DSA. In addition, demographic, clinical and radiographic parameters of all patients were recorded. The outcome was measured based on the modified Rankin Scale (mRS) at six months after admission (favourable mRS score, 0-2 vs unfavourable mRS score, 3-6).
Results: Overall 46 patients underwent EVT and 21 patients NT. Six months after discharge of the SAH patients 24 had a favourable outcome (mRS 0-2) and 16 patients with unfavourable outcome (mRS 3-6). The mortality rate of patients with SAH was 10.1% (n=4) and was alike compared to former studies (11%) on patients with ruptured PAA. Overall aneurysm recurrence was found in six patients (9.4%). All patients with unruptured PAA had a favourable outcome.
Conclusion: EVT and NT of PAAs showed comparable good results, although aneurysm recurrence occurres more often after EVT.
Limitations: The crucial issue of this retrospective analysis is the lower quality/completeness of data compared with prospective data storage.
Ethics committee approval: The ethical approval for this study was provided by the local ethics committee (13-5580-BO).
Funding: No funding was received for this work.

High-resolution MR imaging of cortical layers and their structural alterations in stroke and epilepsy patients
E. Lotan, D. Tanne, Y. Assaf*; Tel-Aviv/IL*

Purpose: We aimed to utilise a non-invasive in-vivo MR-based imaging modality and analysis framework to detect and characterise the laminar components of the human cerebral cortex in stroke and epilepsy patients compared with healthy controls (HC).
Methods and materials: Using 3T-MRI we calculated T1-component probability maps and showed that the T1-signal of the cortex can be divided into 5-6 distinct Gaussian distributions centred at different values, which represent different cortical laminar classes. For the stroke patients, we explored in-vivo if in patients (n=20) with chronic lacunar infarct, involving the corticospinal-tracts (CST), the cortical layers of the connected primary motor cortex (M1) are differently affected. We performed tractography using the infarcts as the seed areas to reconstruct the CST and identified the connected M1. For epilepsy patients (focal cortical dysplasia (FCD) and periventricular nodular heterotopia (PNH); n=9 each) we determined the laminar composition of 78 cortical regions of interest of the automated anatomical labelling (AAL) atlas, which was divided into 1000 sub-areas with equal volume.
Results: For stroke patients we showed focal cortical thinning in the connected M1 and specifically only in its deepest laminar portion as compared to the non-affected contralateral cortex (P<0.001), supporting the concept of secondary neurodegeneration. For epilepsy patients we found widespread cortical dyslamination compared to the HC, supporting evidences of epilepsy as a network disease with disrupted brain connectivity.
Conclusion: Our findings provide a method to calculate and characterise the laminar architecture of the cortex, which was implemented to stroke and epilepsy patient groups. Our method may be used as a sensitive imaging biomarker, and could potentially elucidate pathophysiologic mechanisms and facilitate patient management towards developing individually tailored treatment.
Limitations: Not applicable.
Ethics committee approval: Approved by institutional IRB.
Funding: Not applicable.

Application of low radiation dose combined spectrum and ASIR-V iterative reconstruction in CT scanning of ischaemic stroke: a feasibility study
Y. You*; Chengdu/CN (1390178629@qq.com)*

Purpose: To explore the application of low-dose combined spectrum in CT scan of ischaemic stroke.
Methods and materials: Group A (n=30) used the low-dose scan parameters: 80 kV, 50 mA, and the images were reconstructed by 50% ASIR-V. Head and neck (CTA) Scanning with Spectrum CT, 80-140 kV, 200 mA, the contrast agent volume was 20ml and the flow rate was 4ml/s. The images were reconstructed with 40 keV and 80% ASIR-V. Group B (n=30) used routine scan parameter: CTP:80 kV, 150 mA, CTA :100 kV, 350 mA, the contrast agent volume was 50ml and the flow rate was 5ml/s. The images were reconstructed by FBP. The contrast agent volume was 40ml and the flow rate was 5ml/s in CTP. The quantitative evaluation included: CTP parameters of the hypothalamic, frontal and temporal lobes without perfusion defects at the basal ganglia level, the CT and SD values of the head-neck CTA segments, and the CNR values of M1. The CTP and CTA image quality were also subjectively evaluated by two senior radiologists using a four-point grading scale.
Results: All CTP and CTA images were diagnostic. There were no significant differences in the subjective image, CTP parameters, CTA internal carotid artery and middle cerebral artery and CT value of common carotid artery. There were significant differences in SD and CNR in the common carotid artery. The effective dose and the contrast agent in group A were 58.5% and 23% lower than group B.
Conclusion: The use of low radiation dose combined spectrum and ASIR-V iterative reconstruction in CT scanning of ischaemic stroke.
Limitations: The simple size is relatively small.
Ethics committee approval: Approved by the ethics committee of our hospital.
Funding: No funding was received for this work.

A novel ANG-BSA/Car/ICG MNPs integrated for targeting therapy of glioblastoma
F. Lin*; Shenzhen/CN (foxetfoxet@gmail.com)*

Purpose: The existence of the blood-brain barrier has led to almost all chemotherapeutic drugs and gene drugs failing to effectively achieve and play a role in glioblastoma. So far, the survival rate of glioblastoma patients has hardly improved. In this study, we are aimed to construct an integrated nanoprobe based on albumin nanoparticles for targeted diagnosis and treatment of glioblastoma.
Methods and materials: We constructed bovine serum albumin nanoparticles (ANG-BSA/Car/ICG MNPs) containing SPIO, carmustine and ICG coupled ANG. The in vitro and in vivo MRI/FL dual-mode imaging of glioblastomas in vitro and in vivo were systematically evaluated in order to evaluate the penetration ability of blood-brain barrier and tumour-specific targeting effect. At the same time, through experiments with the control group, we evaluated the ability of ANG-BSA/Car/ICG MNPs to inhibit tumour.
Results: In vitro experiments, we verified that the targeting ability of nanoprobes to glioblastoma cells was significantly better than the control group. In addition, in vivo experiments, nanoprobes significantly increased the accumulation of brain tumours compared with the control group. This targeting imaging and drug delivery system provides an efficient strategy for targeted therapy and intraoperative localisation of glioblastoma.
Conclusion: ANG-BSA/Car/ICG MNPs present a promising potential in multifunctional therapeutic of glioblastoma, and we anticipate that this nanoplatform will be a perfect candidate in glioblastoma theranostic.
Limitations: This study was limited by the lack of comparison with other nanoplatforms.
Ethics committee approval: All animal experiments were approved and conducted according to the principles of the Institutional Animal Care Committee from the Shenzhen Second People's Hospital.
Funding: This study is supported by a grant from Basic Plan Program of Shenzhen, China (No. JCYJ20180228163333734).

MyT3 18-13 11:14
Imaging as the new yardstick for diagnosing peripheral mononeuropathies: a comparison between high-resolution ultrasound and MR neurography with an approach to diagnosis
A. Agarwal Chandra, U. Jaipal, M. Bagarhatta, M. Agarwal, A. Chandra*; Jaipur/IN (a.agarwal.1992@gmail.com)*

Purpose: Peripheral neuropathies are a group of disorders which affect the peripheral nervous system and have been conventionally diagnosed using electrodiagnostic studies. This study was carried out to assess the role of imaging in diagnosing peripheral neuropathy as exact anatomical localisation of

the pathology is possible using high-resolution ultrasound (HRUS) and MR neurography, the modalities assessed in this study.
Methods and materials: A prospective study was carried out in a resource-limited setting on 180 peripheral nerves in 131 patients with symptoms of peripheral neuropathy after taking IRB approval. Each patient underwent HRUS and MR neurography, findings of which were then compared and statistically analysed assuming electrodiagnostic findings as to the gold standard.
Results: Overall, the diagnostic accuracy was highest for the proton density fat saturated (PDFS) MR sequence (93.89%) followed closely by HRUS (80%). The sensitivity was highest for PDFS sequence while the T1 MR sequence had the highest specificity. Combined diagnostic accuracy of both modalities was calculated to be 93.33% with a negative predictive value of 80%. HRUS and MRI equally detected the cases with nerve discontinuity, while neuromas were better identified on MRI.
Conclusion: With the advent of higher frequency probes and improved MR field strength, imaging of peripheral nerves is possible with better accuracy. Imaging assessment of nerves allows anatomical delineation with the identification of the exact site of involvement. This comparative study demonstrates the role of imaging in diagnosing peripheral neuropathies with the accuracy of MRI as high as 93.89% which may serve as an imaging gold standard. HRUS, being quicker, cost-effective and a comparable accuracy of 80% can serve as a reliable screening tool.
Limitations: Resource-limited setting and lack of newer sequences like DTI and DWI.
Ethics committee approval: The IRB approved.
Funding: No funding was received for this work.

Evaluation of parameter changes in lateral lumbosacral radiography of patients with and qithout lumbar spinal stenosis in magnetic resonance imaging (MRI)

N. Merd, D. Gündüz*; Isparta/TR*

Purpose: To investigate the effect of lumbar spinal stenosis (LSS) on objective parameters reflected on radiographs and to adapt existing radiographic indexes to the diagnosis of LSS.
Methods and materials: LSS was determined by measuring the midline anteroposterior (AP) spinal canal diameter on axial T2-weighted images in lumbosacral MRI. Fifty patients with LSS and 50 patients without LSS were classified as. Lateral lumbosacral radiographs of the patients were evaluated retrospectively and on radiographs, pelvic incidence (PI), pelvic tilt (PT), sacral slope (SS), lumbar lordosis (LL), L5 incidence (L5I), L5 slope (L5S), sacral table angle (STA), sagittal vertebral corpus height (SBH), sagittal vertebral corpus width(SBW), peduncular width(PW), foraminal width (FW), posterior pedicle margin (PPM) were measured, SBW/PW and SBW/PPM ratios were calculated.
Results: In the LSS group, PI was significantly higher ($p = 0.029$). FW ($p < 0.001$) and PW ($p < 0.005$) values were significantly lower in the LSS group for each level. In the LSS group, SBH levels were lower ($p=0.041$) at L4 level, SBW levels were higher at L2-5 levels ($p < 0.005$) and PPM values were lower at S1 level only ($p < 0.005$). In the LSS group, the SBW / PW ratio for each level, the SBW / PPM ratio at L4 and L5 levels were significantly higher ($p < 0.005$). In the ROC analysis of parameters with significant differences between LSS and control groups, the cut-off values of significant parameters and levels were calculated.
Conclusion: The results of our study are useful for classifying patients with and without spinal narrow canals, but further studies are required.
Limitations: Inclusion of patients with a single level of a narrow canal in the patient group, not classifying spinal stenosis as developmental or congenital.
Ethics committee approval: n/a
Funding: No funding was recieved for this work.

Automated quantification pipeline (AQuaPi) for the non-invasive measurement of the cerebral metabolic rates of glucose using a fully-integrated PET/MRI

L. K. Shiyam Sundar[1], O. Muzik[2], I. Rausch[1], M. Hienert[1], E. Pataraia[1], E.-M. Klebermass[1], T. Traub-Weidinger[1], T. Beyer[1], M. Bauer[1]; *[1]Vienna/AT, [2]Detroit, MI/US (lalith.shiyamsundar@meduniwien.ac.at)*

Purpose: To introduce AQuaPi, a fully-automated pipeline for PET/MRI to non-invasively determine the cerebral metabolic rate of glucose (CMRGlc) images.
Methods and materials: The pipeline needs the following inputs: (1) PET list-mode data, (2) attenuation correction (AC) map, (3) MR angiography (MRA) images, (4) T1-w MRI and (5) MR navigators. The processing pipeline includes two main components: (i) an image-derived input function (IDIF) component and (ii) a quantification component (QC). The IC component calculates an IDIF by first determining a volume-of-interest through automated segmentation of the MRA, followed by MR navigator-based motion correction (MC) and an MR-based partial volume correction (PVC). The QC then uses the IDIF to generate CMRGlc images. To validate the pipeline, 10 healthy volunteers underwent [18F]FDG test-retest PET/MRI examinations in an integrated PET/MR. Arterial blood samples (AIF) were collected as a reference standard. Pseudo-CT images derived from T1-w MR were used for AC. Absolute percentage difference (APD) in regional MRGlc values (IDIF vs AIF) were determined in the following 6 brain regions: corpus callosum (CC), brainstem (BS), cerebellum (CB), thalamus (TH), anterior cingulate cortex (ACC) and the superior frontal cortex (SFC).
Results: The APD between CMRGlc values obtained from AIF and IDIF were: (5.9 ±3.2%) for CC, (5.9 ±3.3%) for BS, (5.8 ±3.4%) for CB, (5.5 ±3.1%) for ACC, (5.8 ±3.14%) for TH and (5.9 ±3.3%) for the SFC.
Conclusion: We have developed a fully-automated open-source processing pipeline which allows non-invasive determination of absolute CMRGlc values in a clinical setting.
Limitations: Inter- and intra-variability of CMRGlc is high.

Value of routine T_2WI histogram in differential diagnosis of glioblastoma

Z. Ma, X. Zhao*; Zhengzhou/CN (11430884@qq.com)*

Purpose: To study the diagnostic value of T_2 global greyscale histogram in the differential diagnosis of glioblastoma, central nervous system lymphoma and solitary metastasis of three tumour types.
Methods and materials: A retrospective analysis in our hospital had brain MRI examination and 95 cases of pathologically confirmed patients, including 29 cases of glioblastoma (male 13 cases, female 17 cases, mean age 51.2 + 14.5, 10 ~ 69 years old), central nervous system lymphoma 38 cases (male 19 cases, female 21 cases. The average age of 57.1 + 12.5, range 33 to 81 years), 28 cases of solitary metastases (male 15 cases, female 13 cases, average age 59.8, range 36 to 76 years). In three groups of MR T2 axial images with Mazda software will each layer level tumour regions of interest and analyse the global grey histogram, and of the three group parameter features were analysed. The statistical significance between the various parameters.
Results: Through histogram analysis of nine parameters, these nine parameters were statistically significant (all $P < 0.05$), including mean, variance, kurtosis, skewness, Perc.01%, Perc.10%, Perc.50% , Perc.90% and Perc.99%.
Conclusion: T_2 global gray histogram analysis has certain value in differential diagnosis of glioblastoma, central nervous system lymphoma and solitary metastasis, and it can provide new ideas and methods for differential diagnosis.
Limitations: As a retrospective study, it may have a selective bias in clinical cases.

Compare the characteristics of different types of spontaneous intracranial artery dissection on high-resolution MRI vessel wall imaging

B. Tian, X. Tian, Z. Shi, J. Lu*; Shanghai/CN (bing.tian@hotmail.com)*

Purpose: To compare the characteristics of different types of spontaneous intracranial artery dissection on high-resolution MRI (HR-MRI) vessel wall imaging.
Methods and materials: Fifty-six patients with approved spontaneous intracranial artery dissection were scanned on a 3T Siemens Skyra scanner with pre- and post-contrast 3D T1-weighted SPACE. Patients were divided into four groups based on the morphological characteristics of pre-contrast 3D T1-weighted SPACE imaging. Type 1 corresponded to classic dissecting aneurysms, type 2 aneurysms were segmental ectasias, type 3 aneurysms were dolichoectatic dissecting aneurysms and type 4 aneurysms were saccular aneurysms unrelated to the branching zones. Consistency of clinical staging (acute, subacute, chronic stage) and imaging types was evaluated. The characteristics of spontaneous intracranial artery dissection were evaluated including intraluminal contrast enhancement, and artery wall enhancement (grade 0, similar to that of normal vessel walls; grade 1, less than or similar to that of muscle; and grade 2, greater than that of muscle). The characteristics of spontaneous intracranial artery dissection were compared among different types.
Results: Of the 56 aneurysms, 48 were located in the vertebrobasilar system, and the other eight aneurysms were located in the anterior circulation. There were 22 patients for type 1, 10 for type 2, 14 for type 3, and 10 for type 4. Patients were classified into acute (n=18), subacute (n=18), and chronic (n=20) stages according to the time intervals from symptom onset. The clinical staging was in good consistency with imaging types (p=0.000, r=0.732). There was significantly different of intraluminal contrast enhancement and vessel wall enhancement among the four types groups (p=0.030).
Conclusion: The 3T HR-MRI reveals the vessel wall characteristics and provides distinguishing findings between different types of spontaneous intracranial artery dissection.
Limitations: This study was limited by a small number of study groups.

Brain MRI follow-up in children with tuberous sclerosis complex: is gadolinium enhancement always necessary?

A.-L. Gaillard[1], J.-F. Chateil[2], M. Havez-Enjolras[3], A. Crombe[2], P. Bessou[2]; *[1]Saint-Maur-Des-Fossés/FR, [2]Bordeaux/FR, [3]Merignac/FR (a.lisegaillard@gmail.com)*

Purpose: Subependymal giant cell astrocytoma (SEGA) is a brain tumour developed in 10-26% of individuals with tuberous sclerosis complex (TSC). Since they are located near the foramen of Monro, SEGAs can cause obstructive hydrocephalus, leading to increase morbidity and mortality. It is recommended to follow TSC patients with contrast-enhanced (CE) MRIs, but the repetitive use of gadolinium-based contrast agents (GBCAs) may cause gadolinium deposits. Our aim was to compare the performance of CE and non-CE MRI to diagnose SEGA.
Methods and materials: Thirty-five TSC patients were enrolled in this retrospective single-centre study from September 2007 to January 2019 (15/35 (43%) males and 20/35 (57%) females). The inclusion criteria were: diagnosis of TSC on clinical and genetic arguments (according to international TSC consensus conference held in 2012) and at least three-brain MRIs performed for follow-up with a contrast agent injection. In total, 70 MRIs were selected (25 MRIs in the SEGA group and 65 MRIs in the non-SEGA group), two consecutive MRIs per patient were anonymised. Three radiologists performed a double-blinded review of the non-CE and CE MRI sequences. The diagnostic performances were calculated (sensitivity, specificity, positive/negative predictive values and inter and intra-observer agreements).
Results: The performances for the detection of SEGA were good and similar between the CE and non-CE MRIs. Inter-observer agreement was excellent for the two groups (range of Kappa coefficient: 0.81-0.93, p<0.001). The size of nodules near the Monro foramen, intense and heterogeneous contrast enhancement and modifications between two consecutive MRI were significantly associated with the presence of SEGA.
Conclusion: The performances of CE and non-CE MRIs are similar and excellent for detecting SEGA, raising the question of reducing unnecessary gadolinium-chelates injection for TSC patients.

Role of transcranial ultrasound with Doppler and strain elastography in neonatal hypoxic-ischaemic encephalopathy with magnetic resonance imaging as the gold standard

A. Singh, U. Jaipal, D. A. Bhandari*; Jaipur/IN (DrAsthaSingh@outlook.com)*

Purpose: To compare and correlate the diagnostic role of neurosonography with spectral Doppler and strain elastography in neonatal hypoxic-ischaemic encephalopathy with MRI as the gold standard. To assess the role of diffusion-weighted Imaging in early identification and extent of ischemic injury.
Methods and materials: A prospective study was conducted on 50 patients under one month age with a clinical picture of neonatal encephalopathy, a history of perinatal asphyxia and low Apgar score. All patients were graded by Sarnat and Sarnat grading. Neurosonography with spectral Doppler of the anterior cerebral artery and strain elastography was done with 3-7 MHz probe on anterior fontanelle. Elastographic scores were assigned on a five-point colour scale.3 Tesla MRI was done with DWI (diffusion-weighted images). Ultrasound findings were correlated with MRI in various areas of the brain parenchyma and the role of DWI was evaluated by SPSS v.20.0.
Results: The diagnostic accuracy, sensitivity and specificity of neurosonography compared to MRI were 82%, 82.6% and 75% respectively. DWI detected mild ischaemic changes when other MR sequences were negative. Neurosonography detected all cases of germinal matrix haemorrhage and showed better sensitivity for thalamic, basal ganglia and periventricular white matter lesions. Altered RI values of ACA were seen in 59% of moderate and severe cases. Diagnostic accuracy of Elastographic score was 76.67% with a specificity of 86.67% (95%CI;59.54%-98.34%) and sensitivity of 66.67% (95%CI;33.38%-88.18%).
Conclusion: Neurosonography is an effective screening tool for detecting ischaemic encephalopathy. Raised elasticity of periventricular white matter in neonatal encephalopathy points towards its promising role in early diagnosis. DWI detects ischaemic changes earlier than conventional MRI which is important in initiating early management.
Limitations: This study was limited by its small sample size.

Correlation of childhood head injury with clinical and imaging characteristics of Dyke-Davidoff-Masson syndrome

F. Y. Chew, C. Y. Song, W.-C. Shen, Y.-F. Chen*; Taichung/TW (c_fyang@hotmail.com)*

Purpose: To investigate the correlation between childhood head injury and clinical-radiological features of Dyke-Davidoff-Masson Syndrome (DDMS).
Methods and materials: A total of 33 patients with a diagnosis of cerebral hemiatrophy at our institution between January 2012 to July 2019 were retrospectively review. Patients of this study must fulfil the following criteria: (i) clinical presentation of seizure; (ii) radiological manifestations with ipsilateral sulcal enlargement, ipsilateral lateral ventricular dilatation, and ipsilateral calvarial thickening. The patients were distributed into two groups based on the present or absent of childhood head injury. Clinical and imaging characteristics were compared and analysed. Raw data are presented as frequencies and percentages for categories and mean for the age at presentation. Fisher's exact test was used to assess the association between two categorical variables.
Results: There are 14 patients (eight males, six females) aged 1 to 46 years (mean age±SD=20.7±13.8) were included. There are eight patients with childhood head injury and six patients without history of childhood head injury. Clinical features recognised in these two groups are hemiplegia (87.5% vs 66.7% respectively, p=0.539), mental retardation (87.5% vs 66.7%,p=0.539) and psychiatric disorders (37.5% vs 16.7%, p=0.580). Of these patients, radiological appearances of wallerian degeneration and hyperpneumatisation of paranasal sinus (75% vs 50%, p=0.580); elevation of orbital roof (75% vs 33.3%,p= 0.277); hperpneumatisation of the mastoid and elevation of petrous ridge (62.5% vs 16.7%, p=0.138) were found in these two groups. The formation of porencephaly

and midline structural shift were identified among the patients (87.5% vs 16.7%, p=0.026).
Conclusion: The clinical-radiological manifestations of DDMS vary widely. The patients with childhood head injury were more likely to have the formation of porencephaly and midline structural shifts.
Limitations: This study was limited by a small number of patients and by the lack of detailed history and clinical information due to the retrospective nature of this study.

A comparison of time-of-flight MR angiography with sparse under-sampling with TOF-MRA in the evaluation of intracranial aneurysms: digital subtraction angiography as a reference standard
X. Xu, W. Peng, C. Xia, Z. Li*; Chengdu/CN*
(1278240499@qq.com)

Purpose: To compare the performance of time-of-flight with sparse undersampling MRA and TOF-MRA in the image quality and evaluation of size parameters of intracranial aneurysms with DSA as the reference standard.
Methods and materials: 54 aneurysms from 46 patients who underwent TOF-MRA, TOFu-MRA, and DSA were included. For objective image quality, the contrast-to-noise ratio (CNR) and signal-to-noise (SNR) of two MRA images were compared. The subjective image quality was assessed using a 5-point score scale by two experienced observers and the interobserver agreement was determined. With DSA as the reference, the neck, height, and width of aneurysms in two MRAs were measured and compared on maximum intensity projection (MIP) image datasets, respectively.
Results: The SNRs and CNRs in TOFu-MRA (SNR=24.21±8.06; CNR=17.08±7.44) were significantly higher than those in TOF-MRA (SNR=18.94±6.44; CNR=13.27±6.00) (P<0.001). With an excellent interobserver agreement (κ values=0.94), the subjective image quality was significantly improved when the sparse TOF was used ($P < 0.05$). For measurement of size parameter, there were significant differences between TOF-MRA and TOFu-MRA among the three groups (neck, 3.63±2.22 vs 3.52±2.16; width, 4.62±4.59 vs 4.64±4.71; height, 4.62±4.59 vs 4.64±4.71, all P<0.05). Moreover, in the Bland-Altman plot analysis, TOFu-MRA showed no significant differences between DSA.
Conclusion: Compared with conventional TOF, sparse TOF could assess intracranial aneurysms more accurately with a better image quality and the same acquisition time.
Limitations: Further optimisation of the image quality with regard to NO settled protocol parameters would be needed.
Ethics committee approval: The study has been approved by the West China Hospital ethics committee.

RPS 1815-2 10:46
Quantification of the gradient of lumen narrowing of the internal carotid artery on an atherosclerotic plaque from magnetic resonance angiography for the stratification of the risk of cerebral stroke
W. Y. Ussov[1], A. Maksimova[1], V. E. Sinitsyn[2], S. P. Yaroshevsky[1], E. E. Bobrikova[1], O. Belichenko[2]; *[1]Tomsk/RU, [2]Moscow/RU*
(wolfussov@yandex.ru)

Purpose: We proposed a new index of haemodynamic severity of atherosclerotic stenosis of carotid arteries: gradient of narrowing of arterial lumen GNL={(S_{norm}–$S_{stenosis}$)/$D_{norm-stenosis}$}, mm^2/mm, i.e. as ratio of difference between the areas of cross-sections of the artery at the levels of most prominent stenosis and of normal non.stenosed artery closest to it, to the distance between them.
Methods and materials: 25 patients were studied, all with a stenosis of the internal carotid artery (ICA) >50%, (ECST), mono (n=22), or bilateral (n=3). 11 people without ICA stenosis served as the control group. In all participants, MR-angiography was carried out, with the calculation of the GNL on the ICA stenoses. Brain MRI was also carried out on all participants in T1-, T2-, PD-, and flair-weighted protocols.
Results: Patients were assigned to group 1 (n=12, without brain damages), and group 2 (n=13, evidence of earlier ischaemic damages). Group 1 and group 2 did not differ in stenosis % by ECST (74.9±4.25% vs 77.8±3.8%, p<0.05).
Group 1 and group 2 did differ in GNL (2.47±0.41 mm^2/mm and 4.60±0.51 mm^2/mm, p>0.02). GNL in 12 of 13 patients of group 2 was >3.35 mm^2/mm and 9 of 12 in group 1 demonstrated GNL <3.35 mm^2/mm. 2 died due to stroke (GNL 5.5 and 8.6 mm^2/mm)
In controls, the GNL was <0.75 mm^2/mm.
Conclusion: The GNL index, as mm^2/mm, is of diagnostic and prognostic value in carotid atherosclerosis.
Limitations: n/a

A combination method of non-enhanced 3D-TOF MRA, 3D pCASL, and 3D t-ASL: a new quantitative assessment of territorial perfusion shifts and territorial CBF changes in MMD pre-and post-surgery
X. Gao, J. Sun, D. Ma*; Hangzhou/CN*
(10301010213@fudan.edu.cn)

Purpose: To explore intracerebral perfusion and territory shifts conducted by each main artery in Moyamoya disease pre-and post-surgery.
Methods and materials: 27 MMD patients underwent non-enhanced 3D t-ASL, 3D-TOF MRA, and 3D pCASL within one week before and after surgery. T-ASL maps and perfusion shifts of unilateral ICA and bilateral VA were obtained. Perfusion shifts were further subdivided and compared according to MRA. T-ASL images were coregistered to each ASL-CBF maps and created into binary masks. The CBF value was extracted by ASL-CBF maps and all these masks, respectively. A paired t-test was used to compare the surgical side, non-surgical side ICA-CBF, and bilateral VA-CBF, respectively, pre-and post-surgery. Independent two samples t-test was used to compare territorial CBF and its changes before surgery between the haemorrhagic group and the ischaemic group.
Results: 27 (7 haemorrhagic, 13 ischaemic) were enrolled. 4 distinct categories of perfusion territory shifts were observed on t-ASL. Perfusion territory shifts were divided into 2 categories. 7 perfusion territory shifts vanished and 6 appeared after surgery, including both 2 categories. There were significant CBF improvement in the surgical side ICA territory (p=0.004, 95% CI: 3.409-15.150, mean=9.27), non-surgical side ICA territory (p=0.043, 95% CI: 0.130-7.033, mean=3.58), and bilateral VA territory (p=0.003, 95% CI: 2.394-10.332, mean=6.36) after surgery. One patient had decreased CBF in all territories and postoperative ischaemic stroke.
Conclusion: The combination method of non-enhanced 3D-TOF MRA, 3D pCASL, and 3D t-ASL can quantitatively assess territorial perfusion shifts and CBF changes in MMD pre-and post-surgery in a non-invasive, non-radioactive manner. CBF increases in surgical side ICA, non-surgical side ICA, and bilateral VA after surgery.
Limitations: The sample size.
Ethics committee approval: Ethics committee approval obtained.

RPS 1815-4 10:58

The benefits of time-resolved imaging (TRI) in May Thurner syndrome (MTS): a correlation with the degree of iliac vein compression

D. M. D. Araújo[1], M. D. P. Estrela[2], M. M. Filisbino[1], A. Skaf[1], S. D. T. O. Cantoni[1], F. H. C. Souza[1], L. E. C. Paiva[1], H. Leao Filho[1]; [1]São Paulo/BR, [2]Barretos/BR (dyandramoreira@hotmail.com)

Purpose: To assess the benefits of TRI in patients with clinical suspicion of MTS. The main objective is to correlate the presence of a collateral venous pattern in the left inferior limb with the compression degree in the left common iliac vein (LCIV). We also aim to asses the inter and intraobserver variability in the degree of LCIV compression using different techniques.
Methods and materials: This retrospective study included 112 patients submitted to MRI-angiography with TRI sequences using intravenous contrast infusion on the left foot, between October 2014-May 2019. We selected 97 patients who did not undergo any interventional procedures and with an appropriated exam. One senior radiologist reviewed the images looking for collateral venous drainage and measured the maximal degree of LCIV compression. One fellow with 1 year of vascular training measured the maximal degree of venous compression in different sequences, without knowledge of the results from the senior radiologist. The readings took place at different times with each sequence to mitigate memory bias.
Results: We found a statistically significant difference between the presence of collateral venous drainage and the degree of compression with a median LCIV of 0.4 (0.3-0.7) cm in patients without collaterals (67) and a median LCIV of 0.3 (0.2-0.3) cm in patients with collaterals (30), with a p<0.001.
The intraclass correlation (ICC) between techniques by the fellow was 0.81 (IC95%: 0.73-0.87), with a mean variation of 0.11 cm. The ICC between the fellow and senior radiologist was worse, reaching 0.57-0.77 between techniques.
Conclusion: Time-resolved imaging allows a dynamic assessment of collaterals in MTS patients that correlates with the degree of LCIV compression in patients with MTS, but there is relevant variation between readers and techniques.
Limitations: A small sample and single institution.

RPS 1815-6 11:04

A comparison of non-contrast 2D-bSSFP MRI sequence in Marfan patients at 1.5T and 3T: the influence of image quality, discrimination of the aortic wall, and aortic surgery on aortic diameter measurements

M. Avanesov, J. M. Weinrich, M. Sinn, A. Lenz, F. von Düring, M. L. Warncke[2], E. Tahir, G. Adam, P. Bannas; Hamburg/DE (maxim.avanesov@gmx.de)

Purpose: In Marfan patients, accurate aortic diameter measurements are crucial for life-long monitoring. We compared the influence of overall image quality, amount of image artefacts, contrast-to-noise-ratio (CNR), and aortic root surgery on the reliability of aortic measurements of non-contrast MRA in Marfan patients at 1.5T and 3T.
Methods and materials: 40 Marfan patients were prospectively evaluated by non-contrast 2D-bSSFP MRA of the aorta at 1.5T and after 12 months at 3T before (n=24) and after aortic surgery (n=16). Two readers independently rated the image quality and the presence/amount of artefacts on Likert scales at 9 (8) aortic levels before (after) aortic surgery. The CNR of the delineated aortic wall was separately calculated for each aortic level.
Results: Aortic imaging at 3T provided significantly superior CNR and more reproducible aortic diameters compared to 1.5T. Interobserver variances of aortic measurements were significantly smaller at the sinuses of the valsalva, sinotubular junction, mid-ascending aorta, and proximal descending aorta in pre-surgical patients (p<0.05). After aortic surgery, the majority of the advantages of 3T were mitigated by a significantly impaired image appearance due to the higher number of susceptibility/flow artefacts at 3T compared with 1.5T. This resulted in significantly higher aortic diameter variances at the mid-graft and distal anastomosis.
Conclusion: Non-contrast aortic imaging at 3T results in a higher CNR and more reproducible aortic measurement in pre-surgical Marfan patients compared to 1.5T. Most of these advantages are mitigated in post-surgical Marfan patients due to increased susceptibility/flow artefacts at 3T.
Limitations: The time delay between measurements at 1.5T/3T, differences of exact technical parameters at 1.5T/3T, and the measurements only in para-sagittal planes.

Loss of kinetic energy over the aortic arch after surgical repair of acute aortic dissection: a prospective 4D flow study

T. Emrich, N. Ring, C. Bussalb, C. Noll, M. Thalheimer, M. C. Halfmann, C. Düber, K.-F. Kreitner, D. S. Dohle; Mainz/DE (natalie.ring90@gmail.com)

Purpose: 4D flow is an emerging imaging technique. Beside traditional flow parameters, 4D flow enables the calculation of advanced parameters like wall shear stress or the loss of kinetic energy. The aim of this prospective study was to evaluate differences in the loss of kinetic energy over the aortic arch between healthy volunteers and aortic dissection patients after surgical repair with implantation of an antegrade stent-graft ("frozen elephant trunk"; FET).
Methods and materials: In 17 healthy volunteers (HV) and 11 patients, 4D flow imaging was performed using a 4D flow prototype on a 3-Tesla MRI scanner. All patients had undergone aortic surgery for treatment of acute aortic dissection (type A) with supracoronary aortic replacement and "frozen elephant trunk" antegrade stent-graft implantation. 4D flow measurements and a calculation of the loss of kinetic energy (LoE) were performed with a dedicated 4D flow software tool (cvi42, Circle, Calgary, Canada) from the aortic annulus to the descending aorta.
Results: The mean maximum and average LoE was 2-3 times higher over the aortic arch in FET patients compared to healthy volunteers (mean maximum LoE FETvsHV: 9.0± 6.1 vs 3.7±1.3 mW; p=0.016 and mean average LoE FETvsHV: 2.4±1.3 vs 0.9±0.3 mW; p=0.003).
Conclusion: FET repair of acute aortic dissection leads to a significant increase in the loss of kinetic energy measured by 4D flow MR imaging. The prognostic implications of these changes on end-organ perfusion and cardiac remodelling have to be determined in prospective studies.
Limitations: A single-centre study without invasive correlation.
Ethics committee approval: All patients provided written informed consent. The study was approved by the local ethics committee (2018-13520).
Funding: No funding was received for this work.

Non-contrast self-navigated 3D whole-heart MR angiography: performance in aortic root evaluation prior to transcatheter aortic valve intervention

M. J. Pamminger[1], C. Kranewitter[1], C. Kremser[1], B. Henninger[1], G. Reiter[2], D. Piccini[3], G. Klug[1], A. Mayr[1]; [1]Innsbruck/AT, [2]Graz/AT, [3]Lausanne/CH

Purpose: To evaluate the image quality, interobserver reliability, and diagnostic accuracy of self-navigated non-contrast 3D whole-heart magnetic resonance angiography (MRA) for transcatheter aortic valve intervention (TAVI) evaluation in comparison to standardised contrast-enhanced CT angiography (CTA).
Methods and materials: A whole-heart 1.5T MRA was performed in 34 patients (84 years [IQR 79-86], 50% male) for aortic root sizing and coronary ostia height measurement. A subgroup of 19 (56%) patients underwent additional CTA as a gold standard. Image quality was assessed by a 4-point Likert scale, continuous

MRA and CTA measurements were compared with regression and Bland-Altman analysis, with valve sizing by kappa statistics.
Results: The median image quality of MRA was 1.5 [IQR 1.5-2.5]. In 4 patients (12%), 1 coronary ostium each (right coronary artery 3, left main artery 1) was not clearly definable on MRA. The interobserver correlation was substantial to excellent (r=0.61-0.92) with a bias of 19 mm^2 for the annulus area (lower limit of agreement -59 mm^2, upper limit of agreement 98 mm^2; p=0.009). Aortic root and ostia height measurements by MRA and CTA showed substantial to excellent correlation (r=0.65-0.90) with no significant bias (all p≥0.333). The mean annulus area for MRA was 414±71 mm^2 and for CTA 422±80 mm^2 (r=0.9) with bias of -8 mm^2 (lower limit of agreement -79 mm^2, upper limit of agreement -62 mm^2; p=0.333). Regarding prosthetic valve sizing, there was complete consistency between MRA and CTA-based decisions (κ=1).
Conclusion: Self-navigated non-contrast 3D whole-heart MRA enables reliable aortic root measurements without a significant difference to standardised CTA. Prosthesis sizing by MRA measurements would completely match a CTA-based choice. However, in some cases, coronary ostia may not be definable.
Limitations: The comparison of MRA and CTA was only performed in 19 patients.
Ethics committee approval: Local ethics comittee approval was obtained.
Funding: No funding was received for this work.

The role of time-resolved magnetic-resonance-angiography (TRMRA) in the characterisation of soft-tissue vascular anomalies (VA)

A. Sangwan, A. Goyal, A. Kumar, R. Sharma, D. Kandasamy, A. S. Bhalla, D. S. Arava, D. M. Singhal, D. R. Dawar*; New Delhi, Delhi/IN, (ankitsangwanaiims@gmail.com)*

Purpose: To assess the usefulness of time-resolved magnetic-resonance-angiography (TRMRA) in the characterisation of suspected soft-tissue vascular anomalies.
Methods and materials: A retrospective analysis of TRMRA done in patients with suspected VA from December 2017-May 2019 was conducted. TWIST (Siemens) and 4D-TRAK (Philips) sequences were acquired for a 3 minute post-contrast injection. The time-of-onset (TO), time-to-peak (TTP), the pattern of contrast enhancement, presence of feeding arteries, and draining veins were noted. 99 patients were included (60 males, 39 females, age-range 1-65 years) and the diagnosis was confirmed on a composite gold standard.
Results: 29 venous malformations showed gradual progressive filling-in of cystic spaces starting at 8.8+/-3.3s with peak enhancement at 110.3+/-41.08s. 22/29 showed intense-moderate CE with the draining vein in 17/29. 12 arteriovenous malformations (AVMs) started filling at 0.25+/-0.86s with a peak enhancement at 11.58+/-2.9s with hypertrophied feeding arteries, early draining veins, and tubular morphology in all cases. 16/22 cases of fibro adipose VA showed dysplastic veins, non-hypertrophied feeders, and phlebectasia. The mean TO was 8.85+/-4.89s and TTP was 73.66+/-49.38s. 18 vascular tumours enhanced early, homogeneously and intensely (TO 3.27+/-2.94s, TTP 19+/-9.69s), showing the parenchymal type of CE. 12/18 tumours showed hypertrophied feeding arteries and early draining veins. 7 neurofibromas also showed a parenchymal pattern but with delayed onset (5.71+/-5.49s) and peak (84.14+/-51.72s). There was a significant difference between TO and TTP in vascular tumours and neurofibromas (p=0.05, 0.0001, respectively). A significant difference was also seen between TTP of VMs and FAVA (p=0.0005). There was a good correlation with DSA findings (9/12 AVMs, 12/18 tumours).
Conclusion: TRMRA provides dynamic perfusion information for characterisation of VA. It provides vascular roadmaps and helps to assess the feasibility of embolisation/sclerotherapy.
Limitations: A subjective evaluation.
Ethics committee approval: Ethics committee approval obtained.
Funding: No funding was received for this work.

Time-resolved contrast-enhanced magnetic resonance angiography in patients with congenital heart disease: image quality using two different doses of a contrast agent

C. B. Monti, G. Dellaferrera, M. Zanardo, D. Capra, A. Cozzi, F. Sardanelli, F. Secchi*; Milan/IT (caterinab.monti@gmail.com)*

Purpose: To compare the image quality between two datasets of time-resolved, contrast-enhanced magnetic resonance angiography (TR-MRA) with different doses of gadobutrol in congenital heart disease (CHD) patients.
Methods and materials: CHD patients who underwent TR-MRA at our institution were retrospectively evaluated and divided into 2 groups according to the dose of gadobutrol they received: 0.10 mmol/kg (group A) or 0.15 mmol/kg (group B). Signal intensity of 6 different vascular structures, superior vena cava (SVC), ascending aorta (AAo), descending aorta (DAo), pulmonary artery (PA), left pulmonary artery (LPA), and right pulmonary artery (RPA), were reported along with the standard deviation of signal intensity of the background at each timepoint of TR-MRA. The signal-to-noise ratio (SNR) was subsequently calculated for each structure and timepoint. Peak SNRs for each structure were compared between the groups.
Results: A total of 40 patients were included in this study, 20 in group A and 20 in group B. Peak SNRs in group A were SVC: 97.05 (76.10-137.34), AAo: 123.27 (88.69-192.49), DAo: 109.94 (89.10-174.68), PA: 136.03 (93.66-205.37), LPA: 137.84 (82.43-190.33), and RPA: 146.55 (84.50-197.92). Peak SNRs in group B were SVC: 96.71 (49.34-121.72), AAo: 119.11 (79.65-177.98), DAo: 116.56 (87.64-184.21), PA: 126.97 (80.94-170.79), LPA: 124.80 (81.51-176.62), and RPA: 119.56 (80.16-174.25). There were no significant differences in peak SNRs of any structure (p≥0.301).
Conclusion: In CHD patients, TR-MRA may be performed using a dose of 0.10 mmol/kg of gadobutrol instead of 0.15 with no loss of image quality.
Limitations: A retrospective, monocentric study.
Ethics committee approval: Ethics committee approval was obtained. Informed consent was waived due to the retrospective nature.
Funding: No funding was received for this work.

The influence of the pulses and flip angle on the quality of the non-enhanced renal arterial MR images

Y. Wang, F. Hu, S. Yan, D. Ren*; Chengdu/CN (369141717@qq.com)*

Purpose: To investigate the influence of the frequency of pulses and the flip angle on the quality of the non-enhanced renal arterial MRA.
Methods and materials: We prospectively recruited 14 volunteers [19 men, 6 women; age=23.8±2.61].Each volunteer was scanned 6 times with different flip angles (45°, 90°, and 135°) and frequency of pulses (1 or 3 times) with 1.5T MR NATIVE True-FISP sequences. The quality of the images and renal arterials presentation were graded ranging from 0-3 and 1-3, respectively. The average value of the bilateral renal arterials score was used for analysis. ICC was used to test the agreement between the two observers. Factorial analysis was used to compare image quality scores and renal artery scores between different scanning groups.
Results: The interobserver agreement of image quality and renal artery scores were good (ICC =0.77-0.88, 0.80-0.98). There was no difference in image quality and renal artery scores between different pulse groups (p=0.191, 0.177). There was a significant overall difference of image quality and renal artery scores between different flip angle groups (p=0.01, 0.00). There were no statistical significant differences for the interaction of pulse and flip angel in image quality and renal artery scores (p=0.87, 0.52). The image quality and renal artery scores were highest in 135° group.
Conclusion: Different pulse times have no significant effect on the image quality and renal artery display of NATIVE True-FISP sequences. For the flip angel, 135° is the better choice.
Limitations: A lack of objective quantitative parameters. The effect of blood flow velocity on image quality was not considered.
Ethics committee approval: Approved by the hospital ethics review committee.
Funding: No funding was received for this work.

RPS 1815-12 11:40
Free-breathing fast low-angle shot quiescent-interval slice-selective MR angiography for the improved detection of vascular stenoses in the pelvis and abdomen
A. Varga-Szemes[1], E. A. Aherne[2], U. J. Schoepf[1], T. Todoran[1], I. Koktzoglou[3], R. Edelman[4]; [1]*Charleston, SC/US,* [2]*Dublin/IE,* [3]*Evanston/US,* [4]*Illinois/US (vargaasz@musc.edu)*

Purpose: To evaluate the image quality and diagnostic accuracy in the pelvis and abdomen of free-breathing fast low-angle shot (FLASH)-based quiescent interval slice-selective (QISS) techniques in comparison to standard QISS in patients with peripheral artery disease (PAD), using CTA as the reference.
Methods and materials: 27 patients (69±10y) with PAD underwent non-contrast MRA using standard bSSFP-based QISS and prototype free-breathing radial-FLASH and Cartesian-FLASH-based QISS at 3T. A subset of patients (n=22) also underwent CTA as the reference standard. 9 arterial segments per patient were evaluated spanning the abdomen, pelvis, and upper thigh regions. Objective (signal intensity ratio (SIR) and relative standard deviation (SD)) and subjective image quality (4-point scale) and stenosis (>50%) were evaluated by two readers and compared using a one-way analysis of variance, Wilcoxon, and McNemar tests, respectively.
Results: A total of 179 vascular segments were available for analysis by all QISS techniques. No significant difference was observed among bSSFP, radial-FLASH, and Cartesian-FLASH-based techniques in SIR (p=0.428) and relative SD (p=0.220). Radial-FLASH-based QISS demonstrated the best image quality (p<0.0001) and the highest inter-reader agreement (κ=0.721). The sensitivity values of bSSFP, radial-FLASH, and Cartesian-FLASH-based QISS for the detection of >50% stenosis were 76.0%, 84.0%, and 80.0%, respectively, while specificity values were 97.6%, 94.0%, and 92.8%, respectively. Moreover, FLASH-based QISS consistently reduced off-resonance artefacts compared to the bSSFP-based approach.
Conclusion: Free-breathing FLASH-based QISS MRA techniques provide improved image quality and sensitivity, high specificity, and reduced off-resonance artefacts for vascular stenosis detection in the abdomen and pelvis.
Limitations: The limited sample size and lack of a control group.
Ethics committee approval: IRB-approved with written informed consent obtained.
Funding: NIH-NHLBI.

Stent lumen visualisation and quantification with magnetic particle imaging: a systematic in vitro study with 21 endovascular stents
F. Wegner[1], A. von Gladiss[1], J. Haegele[2], U. Grzyska[1], M. M. Sieren[1], K. Lüdtke-Buzug[1], T. M. Buzug[1], J. Barkhausen[1], T. Friedrich[1]; [1]*Lübeck/DE,* [2]*Neuss/DE (franz.wegner@uksh.de)*

Purpose: To investigate whether magnetic particle imaging (MPI) can visualise and quantify the lumen of endovascular stents.
Methods and materials: We investigated 21 commercially available stents (diameter: 3-10 mm, material: stainless steel, nitinol, platinum-chromium, cobalt-chromium) which were implanted in silicone vessel phantoms. All phantoms (stented phantoms and reference phantoms without stents) were filled with tracer dilution (1:100, Resovist, l'rom Pharmaceuticals, Tokio, Japan) and visualised with a preclinical commercially available MPI scanner (Bruker Biospin, Ettlingen, Germany). The quantification of the lumina was performed on the xz-planes of the images based on a calibrated signal intensity threshold.
Results: The visualisation of the stent lumen is feasible without any material induced artefacts. Between the stented phantoms and the reference phantoms there was no visual or quantitative difference observed (stented phantoms/reference phantoms vs nominal diameter r=0.98). The root mean square inaccuracy of stent lumen quantification was below half the spatial resolution.
Conclusion: In principle, MPI is able to depict and quantify the lumina of endovascular stents accurately without material induced effects.
Limitations: The in vitro study design and that we only used a single tracer concentration.
Ethics committee approval: n/a
Funding: This study was partially funded by the Federal Ministry of Education and Research BMBF grant numbers 13GW0071D, 13GW0069A, 13GW0230B, and 01DL17010A.

Automatic scan range delimitation in CT topogram images of the chest using deep learning
K. S. Moon, A. Demircioglu, L. Umutlu, K. Nassenstein*; Essen/DE (moon.kim.mail@gmail.com)*

Purpose: To automate the scan range delimitation in topograms of chest CT exams using deep learning techniques. Automation of this process would free the radiographer from this routine task and could potentially reduce the radiation exposure for the patient due to a stronger restriction of the scan range.
Methods and materials: A total of 1,150 chest topograms of patients (mean age=64.6 years) with pleural effusion (N=360), with atelectasis (N=82), with both diseases (N=21), or without both diseases (N=411) were extracted retrospectively from our PACS, and the scan range was delimitated in each topogram by two radiologists in consensus. A conditional generative adversarial neural network (CGAN) for image-to-image translation was trained on 1,000 topograms to generate virtual scan range delimitations. Quantitative evaluation was performed on 150 randomly selected topograms by computing the absolute difference of the predicted scan delimitations and those of the two expert radiologists.
Results: Automated scan range delimitation showed an excellent agreement with the scan range delimitation of the radiologists. The mean absolute difference between expert radiologists and the prediction of the neural network was 3.77 +/- 0.74 mm and 5.87 +/- 1.29 mm at the upper and lower limit, respectively.
Conclusion: An automated scan range delimitation of chest CT scans using deep learning techniques was trained and evaluated by comparing the scan range with the annotations of two senior radiologists. The results indicate that the conditional generative adversarial network can generate scan range delimitations that are comparable to those of expert radiologists.
Limitations: More training data could potentially increase overall performance. Evaluation from external sites is required to establish the method.
Ethics committee approval: Ethics committee approval was obtained.
Funding: No funding was received for this work.

Elevating clinical brain and spine MR image quality with deep learning reconstruction

L. N. Tanenbaum[1], S. Bash[2], M. Thomas[3], M. Fung[3], R. M. Lebel[4], S. Banerjee[5]; [1]Riverside, CT/US, [2]Los Angeles/US, [3]New York, NY/US, [4]Calgary/CA, [5]Menlo Park/US (nuromri@gmail.com)

Purpose: In the quest for increasing image quality, MR throughput can suffer and manoeuvre, which creates faster scans trade-off quality. There is a need to enhance images without prolonging scan time. Recently, deep learning-based reconstruction methods have shown promise to enhance image value. We evaluated the impact of a new deep learning image reconstruction (DLR) method for both noise reduction and improved image sharpness in clinical MR exams of the brain and spine.

Methods and materials: The investigational DLR leverages a deep convolutional residual encoder network trained on a >10K image database to create images with enhanced SNR and spatial resolution. 28 patients were scanned using clinical 2D brain (3T-7 and 1.5T-4) or spine (3T-12 and 1.5T-5) protocols. K-space data was reconstructed with both conventional and DLR (tuned to 75% noise reduction). Two neuroradiologists independently rated 93 pairs of conventional and DLR images side-by-side. Ratings were based on overall IQ, lesion conspicuity, perceived SNR and resolution, CNR, image texture, and artefact using a 5-point Likert scale (5=excellent, 1=non-diagnostic). A Wilcoxon signed-rank test was used to compare the ratings and inter-rater reliability between readers was assessed using the Bennett S score.

Results: DLR showed statistically significant improvement over conventional images in overall image quality (4.74±0.49 vs 3.27±0.70, p<0.05), lesion conspicuity (4.65±0.49 vs 3.24±0.52, p<0.05), contrast (4.59±0.61 vs 3.50±0.59, p<0.05), perceived resolution (4.66±0.61 vs 3.36±0.59, p<0.05), perceived SNR (4.72±0.60 vs 3.33±0.53, p<0.05), and image texture (4.66±0.60 vs 3.13±0.38, p<0.05). There was a substantial inter-rater agreement with an average S score of 0.66.

Conclusion: Overall IQ improved with DLR with higher perceived SNR, CNR, and spatial resolution compared to the conventional method. Future work will assess whether this technique can accelerate acquisitions while preserving quality.

Limitations: A limited series.

Ethics committee approval: Approved with subject consent.

Funding: No funding was received for this work.

RPS 1805-3 10:52

The effect of deep learning reconstruction on image quality in chest CT

J. Schuzer[1], J. Pack[2], C. Wen[3], C. Steveson[4], S. Rollison[5], J. Yu[2], M. Chen[5]; [1]Vernon Hills/US, [2]Long Beach/US, [3]Orange, CA/US, [4]Adelaide/AU, [5]Bethesda/US (jschuzer@mru.medical.canon)

Purpose: To investigate the effect of a deep learning image reconstruction algorithm on image quality in chest CT scans.

Methods and materials: With institutional ethics approval, 100 consecutive patients underwent chest CT at standard radiation doses on a 320-detector row CT scanner with the following scan parameters: Helical scan, 0.5 mm x 80 detector rows, 120 or 100kV, and automatic exposure control, 0.275s rotation speed and standard pitch. Each scan was reconstructed at 0.5 mm volume and 3 mm axial, coronal, and sagittal slices with both lung and soft tissue kernels using the clinical standard hybrid IR (AIDR3D) and deep learning reconstruction (AiCE) techniques. Images were evaluated for overall image quality, noise, presence of artefacts, contrast, visibility of small structures, and diagnostic confidence using a 4-point Likert scale. SNR and CNR were calculated for each reconstruction. Data was analysed by a paired t-test.

Results: Patients averaged 51.5 years (range 26-78), 77% were female with mean body mass index 27.5±7.1 kg/m2. In image quality, noise, contrast, and visibility of small structures, AiCE performed better than AIDR (3.71 vs 3.06, p <0001; 3.84 vs 2.95, p <0001, 3.66 vs 3.12, p <0001; 3.75 vs 3.16, p < 0001, respectively). The presence of artefacts and diagnostic confidence was not statistically significant for both reconstruction techniques (3.01 vs 2.98, p = 0.49; 4 vs 3.96, p = 0.32, respectively). Signal-to-noise for AiCE images was higher than AIDR3D images (21.0 vs. 16.3 respectively, p <0001). Contrast-to-noise for AiCE images was higher than AIDR3D images (29 vs 23.4 respectively, p <0001).

Conclusion: Deep learning reconstruction improves image quality in chest CT.

Limitations: A single-centre study.

Ethics committee approval: IRB approval National Institutes of Health, USA.

Funding: No funding was received for this work.

The effect of deep learning reconstruction on image quality in abdominal CT

J. Schuzer[1], J. Pack[2], C. Wen[3], C. Steveson[4], S. Rollison[5], J. Yu[2], M. Chen[5]; [1]Vernon Hills/US, [2]Long Beach/US, [3]Orange, CA/US, [4]Adelaide/AU, [5]Bethesda/US (jschuzer@mru.medical.canon)

Purpose: To investigate the effect of a deep learning image reconstruction algorithm on image quality in abdomen CT scans.

Methods and materials: With institutional ethics approval, 100 consecutive patients underwent abdominal CT at standard radiation doses on a 320-detector row CT scanner with the following scan parameters: Helical scan, 0.5 mm x 80 detector rows, 120 or 100kV, and automatic exposure control, 0.5s rotation speed and standard pitch. Each scan was reconstructed at 0.5 mm volume and 3 mm axial, coronal, and sagittal slices with a soft tissue kernel using the clinical standard hybrid IR (AIDR3D) and deep learning reconstruction (AiCE) techniques. Images were evaluated for overall image quality, noise, presence of artefacts, contrast, visibility of small structures, and diagnostic confidence using a 4-point Likert scale. SNR and CNR was calculated for each reconstruction. Data was analysed by a paired t-test.

Results: Patients averaged 51.1 years (range 19-78), 77% were female with mean BMI 27.5±7.1. In image quality, noise, contrast, and visibility of small structures, AiCE performed better than AIDR (3.69 vs. 3.08, p <0.001; 3.87 vs. 2.84, p <0.001, 3.72 vs. 3.17, p <0.001; 3.87 vs. 3.25, p < 0.001, respectively). The presence of artefacts and diagnostic confidence was not statistically significant for both reconstruction techniques (2.98 vs 2.95, p = 0.26; 3.98 vs. 3.95, p = 0.26, respectively). Signal-to-noise for AiCE images was higher than AIDR3D images (4.58 vs. 3.24 respectively, p <0.001). Contrast-to-noise for AiCE images was higher than AIDR3D images (18.48 vs. 13.31 respectively, p <0.001).

Conclusion: Deep learning reconstruction improves image quality in abdominal CT.

Limitations: A single-centre study.

Ethics committee approval: IRB approval National Institutes of Health/USA.

High resolution T2-weighted MRI of the abdomen using deep learning reconstruction

S. Funayama[1], T. Wakayama[2], R. Lebel[3], D. Tamada[1], H. Onishi[1], U. Motosugi[1]; [1]Yamanashi/JP, [2]Hino/JP, [3]Waukesha/US (akchan.acts@gmail.com)

Purpose: To evaluate the feasibility of a deep learning-based reconstruction technique (DLRecon) in clinical abdominal MRI with both standard and high-resolution short scan protocols.

Methods and materials: This study included 23 patients who underwent abdominal MRI. Each patient underwent 3 types of respiratory-triggered T2 weighted fast spin-echo (Discovery MR750 3.0T; GE Healthcare) with the following parameters: standard T2WI (std-T2WI, matrix, 320x192; thickness, 5 mm; NEX, 2), high-resolution T2WI (HR-T2WI, NEX, 1; matrix, 452x192), and super high-resolution T2WI (sHR-T2WI, NEX, 1; matrix, 452x192; thickness, 2.5 mm). The acquired data was reconstructed with and without DLRecon. DLRecon is a new deep learning-based MR reconstruction which comprises of a deep convolutional residual encoder network trained using a database of over 10,000 images to achieve images with high SNR and high spatial resolution. The depiction of anatomical details of the pancreas and the liver, motion artefact,

blurring, and overall quality were assessed to test the differences between those with and without DLRecon. The signal-to-noise ratio (SNR) of liver parenchyma and the spleen-to-liver signal intensity ratios were also calculated.
Results: The depiction of the anatomical details in the pancreas, blurring, and overall quality were improved with DLRecon. The SNR with DLRecon (std-T2WI, 9.99±3.94) was significantly higher than without DLRecon (9.08±2.9, p=0.01). Contrast between the liver and spleen was unaltered, with statistically equivalency at a threshold of 0.2 (std-T2WI, p<0.0001). All the above result trends were the same for HR-T2WI and sHR-T2WI.
Conclusion: The DLRecon provided improved SNR and less burring in abdominal T2WI compared to standard reconstruction for standard and high-resolution protocols.
Limitations: A retrospective study and a small number of patients.
Ethics committee approval: This study was approved by the institutional review board.
Funding: No funding was received for this work.

Influence of a novel deep learning noise reduction technology on filtered back-projected CT images in comparison to iterative reconstruction
A. Steuwe, O. T. Bethge, L. M. Sawicki, J. Böven, J. Morawitz, G. Antoch, J. Aissa; *Düsseldorf/DE (joel.aissa@med.uni-duesseldorf.de)*

Purpose: The software PixelShine (AlgoMedica, Germany) advertises with high-quality images even for low-dose CT acquisitions by reducing noise with deep learning algorithms while maintaining image information. This study aimed at an objective and subjective analysis of the image quality of processed datasets.
Methods and materials: This IRB-approved retrospective study included 27 patients (19 male) who received low-dose abdominal CT (Somatom Definition Flash, Siemens Healthineers) between November 2014 and February 2016. Images were reconstructed with filtered back-projection (FBP, B30f) and iterative reconstruction (IR, I30f, level 3, SAFIRE). Subsequently, FBP-images were post-processed using PixelShine (B30f-PS, PixelShine version 1.2.104, sharpening level 2, noise level 14, processing strength A8, soft kernel settings). CT numbers (mean and standard deviation (noise)) in 6 ROIs (background, paravertebral muscle, fat, spleen, liver, and bladder) and subjective image quality were compared for the different datasets.
Results: Image noise reduced significantly for B30f-PS-datasets compared to B30f- and I30f-datasets (-38 to -50% and -12 to -30% for soft tissues, respectively). CT numbers in liver, spleen, bladder, and fat were constant for all datasets, whereas significant differences were notable for background (B30f-PS vs B30f, and B30f vs I30f) and muscle (B30f-PS vs B30f, and B30f-PS vs I30f). In general, PixelShine improved image quality of B30f datasets considerably. Compared to I30f datasets, liver tissue looked more homogeneous, confirming a lower noise level. Beam-hardening artefacts were neither reduced nor enhanced.
Conclusion: PixelShine reduces noise while maintaining image information with its deep learning algorithm. Especially for older CT scanners, where IR is not available, PixelShine allows to increase image quality. For new scanners, PixelShine allows to reduce patient dose while maintaining image quality.
Limitations: n/a
Ethics committee approval: IRB-approved retrospective study.

Deep learning reconstruction in ultra-low-dose abdominal CT: comparison with hybrid-iterative reconstruction
P. Rogalla[1], S. Kandel[2], B. E. Hoppel[3]; *[1]Toronto, ON/CA, [2]Berlin/CA, [3]Vernon Hills, WI/US (Patrik.Rogalla@uhn.ca)*

Purpose: To evaluate whether deep learning reconstruction (DLR) based on convolutional neural network provides superior image quality in ultra-low-dose abdominal CT compared to the hybrid-iterative reconstruction method.
Methods and materials: 62 patients underwent a CT of the abdomen (135kV, 20-40mA weight-based, 0.5s rotation time, 0.5*80 detector rows, 1.0 mSv reference dose). Four series were reconstructed with 0.5 mm slice thickness: (A) hybrid-iterative IR (AIDR), (B) DLR (combined), (C) DLR (sharp), and (D) DLR (smooth). All images were presented as 3 mm thick slices, 4 on 1 on a 4k monitor in random order and without image annotation. Using forced ranking, 2 readers evaluated the series in the categories of conspicuity, noise texture, low/high contrast detectability, artefacts, and overall appeal. The readers also graded image quality on a Likert scale (1=excellent, 10=low quality). Inter-reader agreement was calculated for all categories. Image noise (SD) was measured in external and intra-abdominal air and liver.
Results: DLR series (B) was generally preferred (rank 1) over all other reconstructions by both readers in all patients and in all categories (p<0.001). The overall mean rank of series (A)/(B)/(C)/(D) were 4.0/2.47/1.10/2.46 and the Likert scores were 6.9/3.4/1.97/3.6, respectively. Inter-reader agreement for forced ranking was k=0.80 and for the Likert score was k=0.78. SDs were 17.23/8.31/7.04/6.32 for external air, 21.5/10.8/10.3/8.3 for intra-abdominal air, and 23.1/9.9/9.3/7.25 for liver tissue, respectively, all p<0.0001 except in group B and C for intra-abdominal air and liver.
Conclusion: Deep learning reconstruction provides superior subjective image quality in ultra-low-dose abdominal CT compared to the current standard-of-care iterative method.
Limitations: The number of readers (2) and patients (62).

Objective and qualitative IQ analyses of deep learning image reconstruction in multiphasic CT imaging of the liver: a patient and phantom study
F. Legou[1], P. Roux[1], V. Barrau[1], H. Pasquier[2], C. Legoff[2], M. Milliner[3], J.-L. Sablayrolles[1]; *[1]Saint Denis/FR, [2]Buc/FR, [3]Creteil/FR (legou.francois@gmail.com)*

Purpose: To evaluate the clinical benefits on image quality (IQ) of TrueFidelity, a deep learning image reconstruction (DLIR), in multiphasic liver CT compared to adaptive statistical iterative reconstruction V (ASIRV) in patients and on a phantom.
Methods and materials: 66 patients underwent a multiphasic liver CT during a 1-month-period. The protocol was tailored according to patient morphology: 80 kV for a body mass index (BMI) <25; 100 kV for 25<BMI<30, and 120 kV for BMI>30. IQ of patient images reconstructed with DLIR and ASIRV50 was assessed on portal phase by measuring liver parenchyma contrast and signal-to-noise ratios (CNR, SNR), and qualitatively by two radiologists using a 5-point Likert-scale. Phantom images acquired with similar protocols were evaluated by computing the noise power spectrum and the task-based modulation transfer function (MTF_{task}).
Results: Compared to ASIRV50, CNR and SNR were significantly improved with DLIR by 71% and 56% at 80, 83% and 77% at 100, and 61% and 60% at 120 kV, respectively (p<0.01 or less). Qualitative IQ was also improved with DLIR for each patient morphology (p<0.0001). On the phantom, compared to ASIRV50, DLIR reduced the noise magnitude by 31% at 80, 100, and 120kV while maintaining a coarser texture (noise mean frequency was 0.22 vs 0.21, 0.23 vs 0.21, and 0.25 vs 0.22 mm^{-1}, respectively). DLIR improved the MTF_{task} at 80, 100, and 120kV (spatial frequency at which the MTF_{task} reduces to 50% was 0.43 vs 0.36, 0.43 vs 0.39, and 0.41 vs 0.37 mm-1, respectively).
Conclusion: Compared to ASIRV50, DLIR improves the IQ of liver CT by reducing image noise without smoothing texture and by improving spatial resolution.
Limitations: IQ of the arterial phases haven't been assessed by the time of the submission. Results under completion.

Evaluation of automated quality control of multicentre clinical trial CT data using spine localisation based on a machine learning method
S. Lee[1], C. Page[2], P. Galette[3], P. Murphy[2], B. Glocker[1]; *[1]London/UK, [2]Stevenage/UK, [3]Upper Providence/US (sarahlee@amallisconsulting.com)*

Purpose: Consistent image quality across multiple centres in clinical trials is crucial. The quality control is typically done by centralising data followed by manual checks prior to radiological review. For evaluating the feasibility of automating the QC process, we developed a software tool, Automatic Visual Quality Control (AutoVQC), that automatically locates the spine, calculates the anatomical field of view (FOV), and detects imaging artefacts using machine learning. AutoVQC was applied to in-house CT data from a multicentre clinical trial.
Methods and materials: The quality of CT scans (in total, 459 series from 62 subjects acquired at 7 sites) was evaluated using AutoVQC, which recognises the anatomical FOV of the images using random forests and detects artefacts such as missing slices. AutoVQC returns two values between 0 (foot) and 1 (top of the head) indicating the FOV in the canonical body axis and the outcome: pass or artefacts. The QC outcome was reviewed and classified as true-positive, true-negative, false-positive, and false-negative, where positive and negative indicate QC pass and artefacts, respectively.
Results: AutoVQC returned the spine localisation result within one minute per series. The result was reviewed for sufficient data quality for subsequent analyses and accurate corresponding canonical body axis range. From all 459 series evaluated, accuracy 0.93, precision 0.89, recall 0.98, and specificity 0.87 were achieved. The causes of artefacts included missing slices, non-axial image orientation, poor image quality, and the presence of multiple series in one single folder.
Conclusion: The initial evaluation of AutoVQC on multicentre study data demonstrated the potential of incorporating it into clinical trial image data management/analysis workflow for quality control of images based on automated spine localisation.
Limitations: A medium sample size.

Artificial intelligence for image-quality control of chest radiographs

K. I. Nousiainen, T. Mäkelä, A. Piilonen, J. I. Peltonen*; Helsinki/FI (katri.nousiainen@hus.fi)*

Purpose: To develop artificial intelligence for evaluating chest radiograph image-quality.
Methods and materials: We considered 3 different features of the image quality: inclusion, rotation, and inspiration. The inclusion was further divided into 4 edges: sin, dex, top, and bottom. The data comprised of 2,019 posteroanterior chest radiographs in an upright position. We annotated the images based on the European Commission's guidelines on quality criteria for diagnostic radiographic images. The inclusion criteria were divided into three classes: too tight, correct, and too wide. The rotation and inspiratory were divided into two classes: ok and not ok. We increased the amount of the image data for the inclusion by cropping the correct images to meet the too-tight criteria and for the inclusion and the rotation by flipping the images horizontally. The image histograms were equalized and the images were resized to a resolution of 512x512 pixels. Approximately 100 and 200 images were extracted for validation and test data, respectively. We trained ResNet50 and DenseNet121 networks with the remaining images.
Results: Resnet50 and Densenet121 both performed accurately for the inclusion detection in sin- and dex-edges. Densenet121 performed better for the inclusion detection in top- and bottom-edges as well as in the patient rotation and inspiration detection. The AUC was > 0.92 for the inclusion detection in all four edges in three classes. The AUC was > 0.71 and > 0.89 for the rotation and the inspiration, respectively.
Conclusion: Artificial intelligence can be used in a clinical setting as instant feedback of the chest radiograph image-quality. Additionally, the trained networks provide a tool for long-term quality control of a radiography unit.
Limitations: Data from only one centre was used.

Adaptive versus fixed artificial intelligence (AI)-based preprocessing for noise reduction applied to routine non-contrast computed tomography scans

C. T. Whitlow[1], A. Hasegawa[2], J. Tan[1], R. Neelmegh[3], J. Vij[3]; *[1]Winston-Salem, NC/US, [2]Chapel Hill/US, [3]Sunnyvale/US (cwhitlow@wakehealth.edu)*

Purpose: Preprocessing CT material density images is a common step for noise reduction, which improves diagnostic image quality. Our study aimed to determine the utility of adaptive artificial intelligence (AI)-based preprocessing for adjusting parameters across each CT slice compared to a similar "fixed" AI-based version that applies the same parameters across all slices. We hypothesised that the adaptive AI-based approach would decrease noise levels across different imaging exams more than the fixed approach.
Methods and materials: This retrospective single-site observational study used head (n=569) and lung-nodule screening (n=276) CT exams acquired over the month prior to analysis on 64-MDCT scanners at standard-dose parameters. Original data was reconstructed as thin-section CT: 1) without preprocessing, 2) with fixed AI-based preprocessing, and 3) with adaptive AI-based preprocessing. The noise was computed as the dependent variable in each case using a manually coded software script and between-group analyses was conducted.
Results: There was a significant ($p<0.05$) between-group reduction in noise level variation, with decreases in noise for the AI-processed compared to the non-processed CT data and greater for the adaptive versus fixed AI-based algorithm. In particular, the standard deviation (SD) for the mean noise was markedly lower for the adaptive versus fixed AI-based algorithm, indicating decreases in image variability across scans.
Conclusion: The adaptive AI-based preprocessing algorithm outperformed the fixed method. In particular, SD differences between methods were more substantial, suggesting less variability in noise levels across cases for the adaptive method. Future investigation is necessary to determine if this algorithm produces image quality that improves sensitivity/specificity for the detection and diagnosis of clinically-relevant pathology.
Limitations: Limitations include relitively small sample-size and retrospective single-site design.
Ethics committee approval: IRB-approved.

Towards AI models that retain accuracy in the real world: a slice-level head CT artefact detector improves the performance of deep learning models

M. Maniparambil[1], S. Chilamkurthy[1], S. Tanamala[1], M. Biviji[2], P. Rao[1]; *[1]Mumbai/IN, [2]Nagpur/IN (mayug.maniparambil@qure.ai)*

Purpose: CT images often have artefacts due to subject motion. These cause mimics leading to false-positives (FPs) for AI models. In this study, we train an artefact-detector model and use this to make a subdural haemorrhage (SDH) detection model robust to artefacts.
Methods and materials: In FP's of the SDH model deployed at an urban outpatient centre, we found that 54% had artefacts. Visually inspecting these scans, we found that the models recognised motion-artefacts as SDH because both were hyperdense areas close to the cranium. We used a manually annotated dataset of 452 scans to train a convolutional neural network (CNN) to detect if a CT slice has artefacts or not. The original SDH model was also a CNN that predicted if a slice contained SDH. This model predicted scan as SDH positive if any slice was predicted positive. We modified this model by discounting the slices predicted as containing artefacts.
A validation dataset collected from the above centre from 06/18 to 01/19 contained 712 scans, of which 42 had SDH and 1,447 (total 22,131) slices had artefacts. Sensitivity and precision were used as metrics for SDH models, while slice-wise AUC for an artefact model.
Results: The original SDH model (sensitivity=1[90%CI 0.93-1] and precision=0.54[90%CI 0.44-0.64]) had 35 false-positives and 0 false-negatives. Quantitative analysis of FPs confirmed that 19 (54%) were due to CT artefacts. Our trained artefact model had slice-wise AUC of 96% [90%CI 0.952-0.967]. The proposed modification to the SDH model (sensitivity=1[90%CI 0.93-1] and precision=0.7[90%CI 0.62-0.81]) had reduced the FPs to 18 (decrease of 48.5%) without introducing any false-negatives.

Conclusion: AI can be trained to effectively detect artefact-ridden slices. This can be used to request reacquisition of an artefact containing scans or make other AI models robust to artefacts.

Deep learning-based reduction of moving CT metal artefacts
T. Lossau, H. Nickisch, T. Wissel, S. Hakmi, A. Saalbach, C. Spink, M. Morlock, M. Grass*; Hamburg/DE (axel.saalbach@philips.com)*

Purpose: Non-static metal implants like pacemakers frequently lead to heavy streak-shaped artefacts in reconstructed CT image volumes. The reliable evaluation of neighbouring anatomy, for instance with regard to inflammation or calcification, might thereby be limited. Furthermore, motion precludes application of standard second pass metal artefact reduction (MAR) methods, which implicitly assume a static object during CT acquisition. We propose a MAR pipeline which is robust regarding motion and applicable on a wide range of scanner types, acquisition modes, and contrast protocols.
Methods and materials: The MAR pipeline uses raw projection data and is therefore independent of 3D motion blur. It is comprised of three convolutional neural network ensembles which are trained from scratch. First, SegmentationNets identify metal-affected line integrals in the input raw projection data. Second, values within the predicted metal shadow are treated as missing data and refilled based on surrounding line integrals by means of the InpaintingNets. The CT volume without metal is obtained by filtered backprojection of the inpainted sinogram. Finally, the ReinsertionNets determine metal positions in the image domain based on the segmented metal shadow.
Results: The data for supervised learning is generated by introducing synthetic metal implants into the projection data of 14 metal-free clinical cases with desired acquisition settings. A pacemaker lead model ensures sensible insertion positions, pathways, and motion trajectories by taking the cardiac anatomy and concomitant ECG-data into account.
Conclusion: The fully automatic pipeline is tested on 9 clinical cases with real pacemakers, whereby ECG-gated, as well as ungated contrast-enhanced CT, scan types are included. Significant metal artefact reduction is achieved.
Limitations: While empirical evaluation was restricted to pacemaker leads, applicability to other metal implants is very likely.
