Abstract:	<p>The Parametric Catalogue of Italian Earthquakes CPTI15 (Catalogo Parametrico dei Terremoti Italiani) represents the latest of a 45-years-long tradition of earthquake catalogues for Italy, and a significant innovation with respect to its predecessors. CPTI15 combines all the information on significant Italian earthquakes of the period 1000-2017, balancing instrumental and macroseismic data. Although the compilation criteria are the same as in the previous CPTI11 version, released in 2012, the catalogue has been revised as concerns:</p> <ul style="list-style-type: none"> the time coverage, extended to 2017; the associated macroseismic data, improved in quantity and quality; the considered instrumental data, new and/or updated; the energy thresholds, lowered to intensity 5 or magnitude 4.0 (instead of 5-6 and 4.5, respectively); the determination of parameters from macroseismic data, based on a new calibration; the instrumental magnitudes, resulting from new sets of data and new conversion relationships to Mw. <p>The catalogue considers and harmonizes data of different types and origins, both macroseismic and instrumental. For all earthquakes, the magnitude is given in terms of true or proxy moment magnitude (Mw), with the related uncertainty. The compilation procedure rigorously implements data and methods published in peer-reviewed</p>

	<p>journals. All data and methods considered are clearly indicated in the catalogue, in order to guarantee the maximum transparency of the compilation procedures. Differently from previous CPTI releases, the final catalogue shows a frequency-magnitude distribution coherent with current instrumental catalogues, making CPTI15 suitable for statistical analysis of the time-space property of the Italian seismicity.</p>
Suggested Reviewers:	<p>Ruben Tatevossian Institut spektroskopii Rossijskoj akademii nauk ruben@ifz.ru</p>
	<p>Dmitry Storchak International Seismological Centre dmitry@isc.ac.uk</p>
	<p>Alessandro Rebez Istituto Nazionale di Oceanografia e Geofisica Sperimentale rebez@inogs.it</p>
Response to Reviewers:	<p>We accepted most of the reviewers' suggestions, as detailed in the point-by-point list attached to the revised manuscript. We thank the reviewers for their comments and suggestions. With respect to the original submission, we included the updated parameter cards to be used as input for the code used for deriving location and magnitude from macroseismic data as Online Resource 2. We renumbered the other Online Resources accordingly.</p>

Acknowledgements

CPTI15 is the result of the work of several authors. Among them, we wish to thank A. Antonucci, R. Azzaro, F. Bernardini, S. D'Amico, E. Ercolani, C. Meletti, A. Rossi, and A. Tertulliani for their contribution to the compilation and revision of macroseismic data and parameters, and their constant support throughout the compilation of the catalogue. Contributions from P. Albini, V. Castelli, C. H. Caracciolo, V. D'Amico, S. Pondrelli, and A. Rebez are also acknowledged.

We thank the countless researchers, from Italy and abroad, and institutions that directly and indirectly contributed data to CPTI15. We are particularly indebted to the authors and contributors of all the previous versions of CPTI, first and foremost to Massimiliano Stucchi.

We are particularly grateful to the compilers of the early catalogues of Italian seismicity for their pioneering efforts in this field, with a special reference to the memory of Daniele Postpischl.

We wish to thank D. Slejko and D. Storchak for their thorough reviews.

The compilation of CPTI15 has partially benefitted from funding provided by the Italian Presidenza del Consiglio dei Ministri - Dipartimento della Protezione Civile (DPC). This paper does not necessarily represent DPC official opinion and policies.

45 **Abstract**

46 The Parametric Catalogue of Italian Earthquakes CPTI15 (Catalogo Parametrico dei Terremoti Italiani)
47 represents the latest of a 45-years-long tradition of earthquake catalogues for Italy, and a significant
48 innovation with respect to its predecessors. CPTI15 combines all known information on significant Italian
49 earthquakes of the period 1000-2017, balancing instrumental and macroseismic data. Although the
50 compilation criteria are the same as in the previous CPTI11 version, released in 2012, the catalogue has been
51 revised as concerns:

- 52 ● the time coverage, extended to 2017;
- 53 ● the associated macroseismic data, improved in quantity and quality;
- 54 ● the considered instrumental data, new and/or updated;
- 55 ● the energy thresholds, lowered to maximum or epicentral intensity 5 or magnitude 4.0 (instead of 5-6 and
56 4.5, respectively);
- 57 ● the determination of parameters from macroseismic data, based on a new calibration;
- 58 ● the instrumental magnitudes, resulting from new sets of data and new conversion relationships to Mw.

59 The catalogue considers and harmonizes data of different types and origins, both macroseismic and
60 instrumental. For all earthquakes, the magnitude is given in terms of true or proxy moment magnitude (Mw),
61 with the related uncertainty. The compilation procedure rigorously implements data and methods published
62 in peer-reviewed journals. All data and methods are clearly indicated in the catalogue, in order to guarantee
63 the maximum transparency of the compilation procedures.

64 As compared to previous CPTI releases, the final CPTI15 catalogue shows a frequency-magnitude distribution
65 coherent with current Italian instrumental catalogues, making it suitable for statistical analysis of the time-
66 space property of the Italian seismicity.

The Italian earthquake catalogue CPTI15

1. Introduction

This new version of the Parametric Catalogue of Italian Earthquakes (Catalogo Parametrico dei Terremoti Italiani, hereafter CPTI15) represents a significant evolution with respect to the previous ones, as far as input data, both macroseismic and instrumental, and parameter determinations are concerned. Besides the extension to the end of 2017, innovations involve the basic macroseismic data, which have been significantly improved as concerns the number of earthquakes supported by intensity distributions and the update of the related macroseismic studies. As for the latter, a number of studies published between 2008 and 2019 were taken into account, together with some older ones not considered in the previous version of the catalogue, released in 2012 (hereafter CPTI11). The criteria for the selection and the harmonization of different types of instrumental magnitudes are completely revised and improved, according to recently published datasets and procedures, as described below. Macroseismic parameters were determined with the same approach as in CPTI11 but the new macroseismic and instrumental datasets provided an updated and more robust calibration of the macroseismic magnitudes. As a specific choice, the catalogue adopts as much as possible peer-reviewed, and publicly-accessible data and procedures, all documented in detail and reproducible.

Another feature of CPTI15, refined with respect to that already experimented in CPTI11, is the presentation and combination of both instrumental and macroseismic parameters. Indeed, when both a macroseismic and instrumental dataset exist for the same earthquake, the two sets of parameters derived from each of them are combined in a “preferred” set. Such a choice aims at maximizing the harmonization of the parameters, especially magnitude, of recent and ancient earthquakes.

The criteria used for the selection of the preferred dataset, for determining earthquake parameters are detailed in the following Sections, together with an overview of the considered datasets.

After a first release of the catalogue in July 2016 (CPTI15 version 1.5), the new CPTI15 version 2.0 has been recently compiled and published, in order to extend the coverage to the end of 2017, including data on the 2016-2017 central Italy seismic sequence. This latest release is the subject of this paper.

Overall, CPTI15 contains 4760 earthquakes occurred in the entire Italian territory and in neighboring areas and seas (Figure 1) in the time period 1000-2017, with a minimum macroseismic intensity of 5 or a minimum magnitude of 4.0. Some earthquakes with magnitude lower than 4.0 are also included in the catalogue, such as i) earthquakes in the Mt. Etna and Neapolitan volcanic areas, and ii) earthquakes in CPTI11 for which the new parametrization reduced the value to $M_w < 4.0$.

For all the earthquakes, the magnitude is given in terms of true or proxy moment magnitude (M_w) and the related uncertainty is provided. All the data considered and methods used are clearly indicated in the catalogue, in order to guarantee the maximum transparency of the compilation procedures. As CPTI11,

115 CPTI15 is not declustered, and thus contains known foreshocks and aftershocks within the considered
116 intensity and magnitude thresholds.
117 The catalogue file (<https://doi.org/10.13127/CPTI/CPTI15.2>) is available for download at
118 https://emidius.mi.ingv.it/CPTI15-DBMI15/index_en.htm, and it is accessible through the dedicated web
119 interface described in Section 7.

120 **2. Background: 45 years of earthquake catalogues in Italy**

121 The need to catalogue all available information on Italian seismicity in the most complete and homogeneous
122 form has been clearly recognized since the dawn of modern seismological science at the beginning of the
123 20th century. In Italy, this need is matched by the extraordinary effort of compiling made by Baratta (1901),
124 the point of arrival of a long tradition of national and regional seismological compilations, based mainly on
125 local historiography. Baratta's compilation was the starting point for the realization of the first Italian
126 parametric earthquake catalogues in the 1970s.

127 The first of such catalogues was compiled by the National Committee for Nuclear Power CNEN (Comitato
128 Nazionale Energia Nucleare; Carozzo et al. 1973) as part of the studies for the program for the construction
129 of nuclear power plants. The CNEN catalogue contains 10,604 entries and covers the time interval from the
130 year 0 to 1971. Among other parameters, it gives date and time, maximum intensity in the Medvedev-
131 Sponheur-Karnik (MSK) scale (Medvedev et al. 1964), the coordinates of the epicentre, the depth, and the
132 magnitude.

133 In 1975 a more extensive catalogue was prepared by Geotecneco, a private firm, for the National Electric
134 Company ENEL (Ente Nazionale Energia Elettrica). The catalogue contains 20,670 earthquakes, covers the
135 years 1000 to 1975, and is available as a computer file (ENEL 1977). The provided parameters are more or
136 less the same as in the CNEN catalogue, with the exception of the intensity expressed in the Mercalli-Cancani-
137 Sieberg (MCS) scale (Sieberg 1923).

138 In 1977, within a major research project of the National Research Council, called "Project on Geodynamics"
139 (Progetto Finalizzato Geodinamica - PFG) a dedicated Working Group acquired the ENEL catalogue with the
140 specific goal of revising and extending it to 1980. The result of this work was the PFG catalogue (Postpischl
141 1985a), compiled by carefully collating the ENEL (1977) catalogue with several other national, and local
142 parametric catalogues (Table 1) and some dozens of historical-seismological ad hoc studies on the 68
143 strongest earthquakes of the Italian seismic history (Postpischl 1985b). The PFG catalogue contains 37,211
144 events (most of them derived from the ENEL catalogue), and covers the period from the year 1000 to 1980.
145 The PFG catalogue was actually published, making available for general use more than 37,000 earthquake
146 records, whereas the previous catalogs were all meant for restricted use only, or available only to scientific
147 institutions. Unfortunately, the PFG catalogue was essentially a patchwork of inhomogeneous components.

148 It is important to stress that the PFG catalogue, as all the parametric catalogues of its generation merged
 149 within it, is largely derived from the parameterization of 19th century seismological compilations, primarily
 150 that of Baratta (1901), while the parameters of the 20th century earthquakes are directly derived from
 151 seismological bulletins (macroseismic and/or instrumental). Overall, only a negligible percentage of events is
 152 based on historical-seismological studies (Camassi 2004).

153 After the compilation of the PFG catalogue, historical investigations were carried on with the involvement of
 154 historians (Stucchi and Guidoboni 1993). Between 1983 and 1988 ENEL promoted a massive historical-
 155 seismological research for the nuclear power plants siting project, involving dozens of historians.

156 After the abandonment of the nuclear power plant projects in 1987, these studies continued in the
 157 framework of a project, supported by the National Institute for Geophysics (Istituto Nazionale di Geofisica,
 158 ING), aimed at the revision of the knowledge on all the “strong earthquakes”, i.e. those with an epicentral
 159 intensity $\geq 8-9$ included in the PFG catalogue. This project, implemented by SGA (a private company),
 160 between 1995 and 2006, produced four different editions of the “Catalogue of Strong Italian Earthquakes
 161 (Catalogo dei Forti Terremoti in Italia, CFTI; Boschi et al. 1995, 1997, 2000; Guidoboni et al. 2007), now
 162 available in a new online version (CFTI5med; Guidoboni et al. 2018, 2019).

163 In the same years, the National Group for Protection against Earthquakes (GNDT - Gruppo Nazionale per la
 164 Difesa dai Terremoti) started the “seismic hazard project”, a five-years research program aimed at realizing
 165 a new national seismic hazard map based on a completely revised and homogeneous earthquake catalogue
 166 (Slejko et al, 1998). The effort resulted in the NT4.1 Catalogue (Camassi and Stucchi 1997), the first in Italy to
 167 be accompanied by an online database (DOM, Monachesi and Stucchi 1997) providing intensity data for more
 168 than one third of the earthquakes.

169 The two groups of researchers merged when joining the National Institute for Geophysics and Volcanology
 170 (INGV - Istituto Nazionale di Geofisica e Vulcanologia) in 1999, and since then continuously revised and
 171 improved the knowledge on Italian earthquakes, starting from historical-seismological investigations, with
 172 important contributions of professional historians.

173 The result of over thirty years of research is the enormous wealth of macroseismic and historical-
 174 seismological data on Italian earthquakes, well represented by the dedicated databases managed and
 175 maintained by INGV, i.e. CPTI15 itself and the associated Database of Italian Macroseismic Data (DBMI15 -
 176 Database Macrosismico Italiano; Locati et al. 2019), the mentioned CFTI5med, and the Archive of Italian
 177 Historical Earthquake Data (ASMI - Archivio Storico Macrosismico Italiano; Rovida et al. 2017).

178 However, it is worth noting that the current knowledge still heavily depends on Baratta’s (1901) compilation.
 179 The newly discovered earthquakes are a limited percentage of those we know today, a detail to be carefully
 180 considered for the evaluation of catalogue completeness (Camassi et al. 2011).

181 As noted above, the PFG and previous catalogues were mainly based on macroseismic information because
 182 a dense network of seismometric stations was not available in Italy until about the end of the 1970s. The first

183 attempt to revise and harmonize the Italian instrumental database dates back to the Italian Instrumental
184 Catalogue (Catalogo Strumentale dei Terremoti Italiani – CSTI; CSTI Working Group 2003, 2005) and concerns
185 the period from 1981 to 1996. In such a work, the arrival times of the INGV Seismic Bulletin have been merged
186 with those of some local networks operating in Italy at the time (OGS, University of Genoa, Macerata
187 Observatory, etc.) and used to relocate all the events with homogeneous methods. The duration and
188 amplitude magnitudes were recalibrated and integrated, according to Gasperini (2002), with a set of ML
189 magnitudes calculated from real Wood-Anderson (WA) instruments (Anderson and Wood 1925) or WA
190 synthetic waveforms from Very Broad Band stations of the INGV Mednet network (Boschi et al. 1991).
191 Afterwards, a similar effort was performed for the period from 1997 to 2002, by Castello et al. (2006, 2007),
192 who produced the Catalogue of Italian Seismicity (CSI - Catalogo della Sismicità Italiana). In the meantime,
193 INGV started releasing online (today at <http://terremoti.ingv.it/>) real-time locations and local magnitudes of
194 the earthquakes detected by the Italian National Seismic Network. Such data are periodically revised and
195 published on a three-months basis in the Italian Seismicity Bulletins (BSI - Bollettino Sismico Italiano;
196 Margheriti et al. 2016, 2016a, 2016b, 2017, Nardi et al. 2016, Rossi et al. 2017, Battelli et al. 2018, Cantucci
197 et al. 2019, Lombardi et al. 2019).

198 **3. Macroseismic data and parameters**

199 The quality and reliability of a parametric earthquake catalogue strongly depend on i) the quality and
200 accuracy of the basic data from which earthquake parameters are derived, and ii) the reliability of the
201 methodology used for deriving such parameters.

202 Usually, macroseismic data used for the compilation of earthquake catalogues consist of earthquake studies,
203 intensity data points, previous catalogues, etc. Such a material is often unpublished and available only to the
204 catalogue compiler(s), and the procedures applied to the assessment of the parameters are poorly
205 documented, or not documented at all. Following the tradition summarized in the previous Section, the
206 criteria adopted for the compilation of CPTI15 aimed at providing the best possible results in terms of
207 reliability and transparency of the compilation procedures. Since most of the content of any catalogue
208 covering a time span of more than 1000 years is necessarily macroseismic, the first step in the compilation
209 of CPTI15 consisted in selecting the best available macroseismic data.

210 Since the compilation of the NT4.1 catalogue (Camassi and Stucchi 1997), a comprehensive archive has been
211 built and continuously implemented, with the scope of collecting and qualifying the necessary macroseismic
212 datasets. Because different datasets may refer to the same earthquake and provide coinciding, conflicting,
213 or complementary information, such an inventory was used to compare them and to identify the best
214 available dataset for each earthquake. In addition, the inventory includes instrumental data of recent
215 earthquakes, in order to select also the most robust instrumental parameters, whenever available. As shown
216 in Stucchi et al. (2013), the described procedure ensures the control and transparency of the flow of

information from the earthquake descriptions provided by historical sources to the earthquake parameters, via the assessment of macroseismic intensity data points (or macroseismic data points, hereafter MDPs). In addition, problems related to both duplicate and fake events are easily dealt with. Through time, the archive content has been digitized as much as possible, and it has been organized by means of a relational database structure similar to that adopted by its European counterpart, the European Archive of Historical Earthquake Data (AHEAD; <https://www.emidius.eu/AHEAD/>), described in Locati et al. (2014), and Rovida and Locati (2015). The Italian archive has been recently made accessible on the web with the name of ASMI “Archivio Storico Macrosismico Italiano” (Italian Historical Macroseismic Archive, https://emidius.mi.ingv.it/ASMI/index_en.htm; Rovida et al. 2017), making available all the background knowledge upon which CPTI15 is built. Figure 2 illustrates the scheme used in the compilation of the catalogue and the relationships among input data, ASMI, DBMI15, and CPTI15.

3.1 Macroseismic data: DBMI15

The collection and systematic archiving of the most recent and significant studies facilitated the creation and update of the list of earthquakes to be included in the catalogue, and the selection of the study that represents the most complete knowledge and provides the most robust data upon which to build the catalogue entry.

The MDPs supplied by the studies selected for each earthquake constitute DBMI15, the 2015 version of the Italian Macroseismic Database (Locati et al. 2019). The main goal of DBMI15 is to both collect and harmonize the sets of MDPs upon which CPTI15 is built, and to provide reliable seismic histories of Italian populated places, i.e. the list of earthquake effects, in term of macroseismic intensity, that were recorded at a given place.

Studies providing data to DBMI are selected, as much as possible, according to the criteria described in the following. 1) The study must provide a set of MDPs for one or more earthquakes, defined in terms of place name, possibly its geographical coordinates, and a value of macroseismic intensity expressed according to a published macroseismic scale. 2) The study should be published, either in a scientific journal or in a technical report. 3) The study should possibly describe the process that ended in the assessment of the provided intensities, mentioning the considered sources of information and how they were interpreted. In case multiple studies are providing alternative sets of MDPs, the selection takes into account many aspects, such as the historical sources used by the authors of the study, the number of MDPs provided and their geographical coverage. The date of publication is mostly irrelevant in the selection process as the most reliable study is not necessarily the most recent.

The selection process resulted in 189 studies (listed in Table ES1 in Online Resource 1) providing MDPs related to 3219 earthquakes, with a total of 123,756 MDPs.

The number of considered data sources and provided data represent a wide heterogeneity of approaches and ways of presenting intensity data. For compiling a homogenous set of MDPs to be used in CPTI15, original

MDPs are re-compiled, although preserving as much as possible the original information as provided from the study. For this purpose, all the three components of a MDP, i.e. intensity, place coordinates, and place name, are re-processed and harmonized.

All intensity values are re-compiled using Arabic numerals, with uncertain intensities expressed using a hyphen (e.g. 6-7). Reported unconventional, descriptive intensities such as “felt” or “damage” are reduced to a list of standardized codes (Table 2). To be used as input for the assessment of earthquake location and magnitude, intensity values have to be expressed also as numerical values. Uncertain intensities are treated as half values, e.g. 6.5 for 6-7, and alphanumeric codes are associated to the numeric values in Table 2.

The uncertainty reported by a study is sometimes expressed as a wide range of degrees, and intensities such as 5-7 or 3-5 might appear in the original data. Such values, besides being not consistent with the practice of intensity assessment provided in Grünthal (1998), cannot be directly used in the calculation of earthquake parameters, and an average value cannot be adopted. In such cases, one of the defined non-conventional descriptive values (e.g. “HD”, “D”, or “F”) is assigned, selecting the code that better matches the indications provided by the EMS-98 scale (Table 3).

A first step in the homogenization of the original intensities with the abovementioned criteria resulted in the recompilation of 59283 observations as reported in Table 4.

A second aspect in the homogenization of intensities deals with those intensities referred to localities that do not comply with the requirements of the macroseismic scale, such as settlements made up of very few or sparse buildings. Such cases are marked in DBMI15 as “Special cases”, according to the codes described in Table 5, and the intensity value attributed by the study is retained. In the cases of single isolated buildings (“IB”) and wide geographical areas (“TE”), the provided values are converted into descriptive codes, for the latter no coordinates are associated to the MDP.

The intensity data contained in DBMI15 are referred to a Gazetteer of geographical coordinates and place names that was created and managed in-house since the first release of DBMI, called DOM (Monachesi and Stucchi 1997). The Gazetteer contains data related to about 87,000 Italian localities, each associated with a unique identifier, a pair of coordinates and the modern, official place name, and census information periodically published by the Italian National Institute of Statistics (ISTAT).

3.2 Macroseismic parameters

The selected MDPs distributions were used to derive location and magnitude for earthquakes in both the “pre-instrumental” and “instrumental” periods. The procedure selected for such a purpose is the Boxer method (Gasperini et al. 1999, 2010). The main reason for choosing Boxer is the continuity with the previous CPTI04 and CPTI11 versions, and with the “SHARE European Earthquake Catalogue (SHEEC) 1000-1899 (Stucchi et al. 2013). For the same reason, among the location methods implemented in the latest version of the code (Boxer 4.0; Gasperini et al. 2010), we mostly relied on the so-called “method 0”, which determines

the epicentre as the barycentre of the data points with the highest intensities. Such a method guarantees the stability of the solution even with few or irregularly distributed data. As a drawback, Boxer solutions are not reliable when MDPs are absent in the epicentral area, and it does not assess the hypocentral depth. The latter, however, is rather unreliable even when instrumentally determined for crustal earthquakes occurred before the last decades.

For the computation of magnitude, Boxer relies on a calibration against earthquakes with both reliable macroseismic intensity data and known instrumental magnitude and location. The empirical method used by Boxer to relate macroseismic data with magnitudes is based on the formula by Sibol et al. (1987):

$$M_i = a_i + b_i \log_{10}^2(A_i) + c_i I_0^2 \quad (1)$$

where M is magnitude, A_i is the area of a circle with a radius equal to the average epicentral distance of places whose observed intensity belongs to the i -th intensity class (see below), I_0 is the epicentral intensity, and a_i, b_i, c_i are empirical coefficients to be calibrated for each i -th intensity class by means of a procedure described in Appendix 1 of Gasperini et al. (2010). Following Gasperini and Ferrari (1995, 2000), the Boxer method computes the earthquake magnitude as the weighted average of the values independently obtained from each i -th intensity class through Equation (1), with a weight that is inversely proportional to the number of intensity data and to the square of the standard deviation of the regression for the corresponding intensity class.

For CPTI15 the calibration of the coefficients was updated with respect to that used for CPTI11 that dated back to the compilation of the 1980-2002 portion of CPTI04 (Gasperini 2004). The new calibration derives from a dataset related to 354 earthquakes homogeneously spread throughout Italy, and with both instrumental magnitudes, either M_w or M_w proxy, between 2.8 and 7.1 (Figure 3A) and macroseismic data (30138 data points, with intensity between 2 and 11 MCS; Figure 3B). Only earthquakes shallower than 30 km and with more than 10 intensity data were included in the calibration dataset, and those earthquakes with partial or incomplete intensity distributions (e.g. earthquakes at sea) were discarded.

Instrumental magnitudes of the calibration earthquakes include both true M_w derived from moment tensor inversions as well as proxy M_w computed from other types of magnitudes as described in the following section, in order to ensure magnitude (or intensity) and temporal coverages as wide as possible. Sixteen intensity classes, ranging from 2 to 9 with intermediate uncertain values and “felt” as an independent class, were calibrated. Intensities classified as “felt” are assigned to a separate class because of their significant number in the macroseismic database, and the very wide range of epicentral distances at which such intensity is classified. According to Stucchi et al. (2007), and Locati et al. (2019) a conventional numerical value of 3.9 has been assigned to Felt.

The coefficients are shown in Table 6, together with the three additional parameters needed for defining the weight of each intensity class in the magnitude calculation: the standard deviation of the regression s , the

weight normalization factor K , and the number of degrees of freedom of the regression (see for details Gasperini et al. 2010, Appendix 1).

Figure 4 shows the results of the calibration procedure as the comparison between the observed instrumental M_w magnitudes (M_{obs}), and the corresponding values calculated from intensity data (M_{calc}), using the coefficients in Table 6, for the 354 calibrating events. The agreement is reasonably good for $M_{obs} \geq 4.0$, whereas for lower magnitudes M_{calc} significantly overestimates M_{obs} (Figure 4a). The residuals $M_{obs} - M_{calc}$ show a fairly Normal distribution (skewness=-0.17, kurtosis=0.29) with average -0.08 and standard deviation 0.40 (Figure 4b).

Boxer calculates magnitude with the described procedure only if at least two intensity class contains at least two MDPs or if a single intensity class contains at least four of them. In case the available MDPs are insufficient to apply such method, the magnitude is calculated by an empirical linear relationship between epicentral intensity I_0 and moment magnitude M_w . The calibration dataset was also used for deriving the coefficients of such a relationship, as follows:

$$M_w = (0.4667 \pm 0.0191) I_0 + (1.8267 \pm 0.1571) \quad (2)$$
$$std = 0.11; R^2 = 0.99$$

The parameters cards with the newly calibrated coefficients to be used as input (“inpparm.dat” file) for the Boxer code are reported in Online Resource 2.

The macroseismic magnitudes in CPTI15 are determined for 3005 earthquakes, 54% of them is calculated using MDPs distributions as described above, and 36%, related to poor intensity distributions, with the new I_0 -to- M_w relation. The remaining 10% of magnitudes concerns earthquakes in the Mt. Etna volcanic area for which macroseismic magnitude was calculated using the empirical relationship between I_0 and M_L by Azzaro et al. (2011), then converted to M_w with the relationships by Tuvè et al. (2015), both specifically calibrated for the Etnean area. In the lack of any specific relationship, the I_0 -to- M_d relationship by Tuvè et al. (2015) was applied in the Phlegrean volcanic area and at Ischia Island, with the obtained M_d values converted to M_w using the relationship by Petrosino et al. (2008), specific for the area.

In a few cases, the epicentre estimated by Boxer as the barycentre of the highest intensity points (“method 0”) conflicts with the likely location offshore or in coastal areas of the earthquake. In such cases, the epicentre was assessed using “method 4”, which derives the hypocentral location (latitude, longitude, and depth) and the expected epicentral intensity through the attenuation relation proposed by Pasolini et al. (2008), as described in Gasperini et al. (2010). New coefficients (a , b), and a new reference depth (h) of the relationship by Pasolini et al (2008), were also derived from the same calibration dataset described above: $a = 0.00289 \pm 0.00021$, $b = 1.248 \pm 0.019$ and $h = 7.45 \pm 0.28$, as well as a new relationship between the expected intensity at the epicenter (I_E) and M_w :

$$I_E = (0.650 \pm 0.021) M_w + (0.799 \pm 0.123) \quad (3)$$
$$std = 0.395$$

CPTI15 provides macroseismic locations for 3009 earthquakes, calculated with Boxer “method 0” for the 94% of the cases. Boxer “method 4” solutions proved to be stable only with more than 10 MDPs, and for this reason it was used only as an alternative to “method 0” for only 63 earthquakes. For 33 earthquakes, labelled in the catalogue file, usually with few MDPs, the solution by Boxer resulted inconsistent with the intensity distributions, and the epicentre was modified either assuming it as coinciding with the point of maximum intensity or excluding one or more high-intensity data points (assumed to be outliers) from the processing. Finally, for 79 earthquakes in the Mt. Etna area the location proposed by the reference macroseismic study, determined by taking into account also the observed coseismic surface faulting (see Azzaro et al. 2000), was preferred to that derived from the available MDPs.

The uncertainty associated with the epicentral coordinates, as calculated by Boxer by both “method 0” and “method 4” is available for 2033 earthquakes, i.e. with enough intensity data. The uncertainty associated to the macroseismic magnitude computed through the intensity distributions, with 0.10 as a minimum value, is always reported in the catalogue. The uncertainty associated with magnitudes derived from epicentral intensity through Equation 2 was assumed equal to 0.46, corresponding to the standard deviation of the distribution of the individual earthquakes in the calibration dataset.

4. Instrumental data and parameters

As already mentioned in the introduction, the instrumental catalogues CSTI and CSI report revised locations and magnitudes of Italian earthquakes from 1981 to 2002. Although in the following years some research projects aimed at the continuation of such work, no official releases have been published until now and then for the years following 2002 one has to refer to the Italian Seismic Bulletin (Bollettino Sismico Italiano - BSI) and the Italian Seismological Instrumental and Parametric Database (ISIDe; ISIDe Working Group 2007) of INGV. Over time, this latter was subject to several changes in both the format and the methods of parameter determinations. From 2003 to 30 April 2012 the official BSI source is the website <http://bollettinosismico.rm.ingv.it>, which provides fortnightly summary files of hypocentral locations and magnitudes. However, starting from 16 April 2005 the most comprehensive and complete source of preliminary and revised location and magnitudes of INGV became the Italian Seismic Instrumental and parametric Database (ISIDe). Actually, since the beginning of May 2012 the location software that feeds ISIDe with real-time locations and magnitudes was updated to Earthworm (Johnson et al. 1995). This change implied that the duration magnitude M_d was not provided anymore for most earthquakes. The ISIDe website was dismissed at the beginning of 2017 and replaced by a new data portal (<http://terremoti.ingv.it/>) and web services (<http://webservices.ingv.it>), which include and provide also the revised data of BSI for the period 1 May 2012 - 31 August 2018 (Margheriti et al. 2016; 2016a; 2016b; 2017; Nardi et al. 2016; Rossi et al 2017; Battelli et al. 2018; Cantucci et al. 2019; Lombardi et al. 2019; Melorio et al 2019; Bono et al. 2019).

388 The heterogeneity of the procedure used in the course of time to compute magnitudes prevents the simple
389 direct use of such data to compile a harmonized catalogue of Italian seismicity. Hence, Gasperini et al. (2013)
390 recalibrated the local and duration magnitudes of CSTI, CSI, and BSI from 2003 to 2010 through the
391 comparison with a harmonized dataset of Mw magnitudes from various MT databases (Gasperini et al. 2012),
392 using general orthogonal regression (GOR) methods (Fuller 1987; Stromeyer et al. 2004; Castellaro et al.
393 2006; Lolli and Gasperini 2012). The same regression equations obtained by Gasperini et al. (2013) for the
394 period from 16 April 2005 to 2010 have been used for converting to Mw even the Md and ML of ISIDe from
395 2011 to the present. Recently, Lolli et al. (2018) extended the harmonization in terms of Mw to local
396 magnitudes of Italian earthquakes from 1960 to 1980, using similar methods. As such work was not yet
397 published at the time of the compilation of the first version CPTI15, only few magnitudes from a preliminary
398 version of the paper were actually used in case no other magnitude were available for a given earthquake.
399 Instrumental locations and magnitudes for the Italian region are also provided by the Bulletin of the
400 International Seismological Centre (ISC 2019) starting from 1964. ISC Bulletin reports MS and mb computed
401 according to international standards (Bormann et al. 2013) using the amplitude and period data provided by
402 contributing institutions. Lolli et al (2014, 2015) computed conversion equations from MS and mb from ISC
403 to Mw at the Global, European and Italian scale by GOR methods. Another compilation of Italian magnitudes
404 is provided by Margottini et al. (1993), who collected ML, MS and mb of Italian earthquakes from 1903 to
405 1986 by rereading seismograms and original bulletins. As MS and mb from Margottini et al. (1993) also
406 conforms to international standards, their conversion to Mw is made using the same equations used for ISC.
407 Conversely, the conversion of ML from Margottini et al. (1993) does not require any computation because,
408 according to Gasperini et al. (2013), it coincides with Mw within the error bounds.
409 All this patrimony of instrumental information has been considered to compile CPTI15. We proceeded by
410 integrating the list of earthquakes having known macroseismic effects with locations of instrumental
411 earthquakes (with $M_w \geq 4.0$) not matching any of the previous ones. Even if we should expect that a $M_w \geq 4.0$
412 should have been felt by the population, the reasons for the possible omission of macroseismic information
413 might be manifold.

414 **4.1. Instrumental locations**

415 Given the different characteristics and time coverages of the mentioned data sources, the selection of the
416 “preferred” instrumental location was performed according to a temporal priority scheme, as follows:

- 417 1. CSTI1.1: 1981 - 1996
- 418 2. CSI1.1: 1981 - 2002
- 419 3. BSI: 2003 – 2017 (April)
- 420 4. ISIDe: 2017 (May-December)

421 Even if both CSTI and CSI cover the interval 1981-1996 the preference was generally given to CSTI because
 422 CSI discarded many magnitudes, and does not adopt any criteria to discard unreliable locations outside the
 423 coverage of the Italian seismic network.

424 To ensure the best solution among the available ones, the adopted priority scheme was integrated with other
 425 data sources for particular areas of the Italian territory. Locations provided by the Bulletin of the ISC
 426 (International Seismological Centre), available for earthquakes up to June 2016 at the time when CPTI15 was
 427 compiled (beginning of 2019), were selected for deep events in the Tyrrhenian Sea and for many other
 428 earthquakes outside the coverage of the Italian seismic network (e.g. Central Adriatic Sea, Ionian Sea, Sicily
 429 Channel, Western Tyrrhenian Sea).

430 In some 30 cases, the priority scheme described above was not applied because the “preferred”
 431 determination proved to be inconsistent either with the other existing instrumental solutions or with the
 432 reported intensity distributions. For some other earthquakes, the “preferred ” dataset does not provide any
 433 epicentre, contrary to other “unpreferred” ones. In all such cases, the choices also took into account the
 434 quality of the data, verifying the number of phases, the azimuthal gap, the distance from the closest station
 435 etc.

436 Data from local catalogues and bulletins, such as the Bulletin of the OGS (Istituto Nazionale di Oceanografia
 437 e Geofisica Sperimentale) for Northeastern Italy or different instrumental catalogues for the Mt. Etna
 438 volcanic area (Patané et al. 2004; Distefano and Di Grazia 2005; Barberi et al. 2016) have been preferred in
 439 their respective areas and time windows. The instrumental catalogues of France (SI-Hex; Cara et al. 2015)
 440 and Slovenia (Živcic 2009, for events after 1973) were also considered.

441 The lack of any reliable instrumental catalogue for the Italian territory before 1981 forced the search for
 442 instrumental epicentres in alternative European and global datasets. The only published Italian instrumental
 443 locations are contained in the predecessor of the abovementioned BSI, the “Bollettino Sismico Mensile”,
 444 published on a monthly basis by Istituto Nazionale di Geofisica (now INGV) since its foundation. Such a
 445 bulletin contained mixed data about earthquakes in the Italian territory (and abroad) consisting mainly in
 446 phase arrivals, in a few cases complemented by hypocentral coordinates, most of which are not calculated
 447 but rather reported from international agencies or assessed from macroseismic data (also reported in some
 448 cases). In this situation, the main source of epicentral locations was again the ISC reviewed bulletin, which
 449 provided 274 determinations from 1957 to 1981. These were selected as the preferred instrumental solution
 450 all over this period. An alternative source of data for the same period is the list of “Preliminary
 451 Determinations of Epicenters” of the United States National Earthquake Information Center – the so-called
 452 NEIC-PDE catalogue. For the period before 1963, also the International Seismological Summary (ISS), and the
 453 monthly bulletins of the Bureau Central International de Séismologie in Strasbourg (France) were considered.
 454 Important contributions for Northeastern Italy came from Sandron et al. (2014) and Slejko et al. (1999), who
 455 provide revised locations for 374 earthquakes from 1901 to 1976 in the Eastern Alps and for the 1976 Friuli

sequence, respectively. Seven more published papers on the (re)assessment of the epicentres of significant earthquakes were also taken into account, although not systematically. The full list of catalogues and databases contributing instrumental locations is presented in Table ES2 of Online Resource 1.

4.2. Selection and harmonization of instrumental magnitudes

Following the criteria described in Gasperini et al. (2012), a total of 953 moment magnitude estimates provided by the catalogues of moment tensors listed in Table 7 were considered, related to earthquakes between 1976 and 2017. When different catalogues provide alternative M_w estimates for the same earthquake, the different M_w values were combined and harmonized according to Gasperini et al. (2012). As a result, M_w estimates from moment tensor inversions, ranging from 3.9 to 6.8, are available for 614 earthquakes, representing 13% of the catalogue (see also Figure 7). The uncertainty associated to M_w estimates was determined according to Gasperini et al. (2012), as well. The complete list of catalogues providing magnitude estimates is given in Table ES3 of Online Resource 1.

Lacking moment magnitude determinations from moment tensor inversions, other types of instrumental magnitude of different origins were considered, and converted to M_w , for a total of 1754 magnitude estimates. For the main portion of the catalogue, in the time period from 1981 to 2017 different types of local magnitude provided by the CSTI1.1 (CSTI Working Group 2005), and CSI1.1 (Castello et al. 2006) catalogues, and by the Seismic Bulletin and ISIDe database of INGV were considered. Magnitudes from such catalogues were selected, converted to M_w , and combined according to Gasperini et al. (2013), as shown in Table 7.

For the period between 1964 and 1980, MS and mb values from the ISC Bulletin were mainly selected, and they were complemented with estimates from the catalogue by Margottini et al. (1993). MS and mb values were treated and converted to M_w according to Lolli et al. (2014; 2015). M_w proxies derived from mb and MS estimated by ISC were considered also in the period from 1981 to 30 June 2016 and combined, through the average weighted with the inverse of the square of the uncertainty, with values derived from ML. For deep earthquakes (mainly in the Southern Tyrrhenian sea area) or those located out of the coverage of the Italian seismic network, M_w proxies from ML are discarded. In the period 1972-1980, Wood-Anderson (WA) ML determined either by Monte Porzio observatory in Rome and contained in the ING Bulletin, or by the Trieste station and published in Sandron et al. (2015) were also considered. The first ML WA values were converted to M_w by adding a fixed offset of 0.22 magnitude units (Lolli et al. 2018), for the latter the conversion proposed by Sandron et al. (2015) was adopted. Proxy M_w derived from ML WA were combined with those derived from ISC, when both available (see Table 7). Lacking any other determination, ML values from the PFG catalogue (Postpischl 1985a) were used considering them as equivalent to M_w , as deduced from the comparison with ISC data (Lolli et al. 2018). A few mb and MS estimates from Margottini et al. (1993) were considered also for earthquakes occurred before 1963.

490 As a conclusion, the overall priority scheme for the selection of instrumental magnitudes is shown in Table
491 7.

492 In addition, moment magnitudes derived by Bernardi et al. (2005) for 12 earthquakes with epicentres in
493 Switzerland and by Pino et al. (2000) for the 28 December 1908 earthquake (Messina straits) were taken into
494 account.

495 As for earthquakes in the Etna volcanic areas, apart from Mw from moment tensor solutions, instrumental
496 magnitudes were selected from the available local catalogues and specific conversion relations were used as
497 shown in Table ES4 of Online Resource 1.

498 **5. Results of compilation**

499 As shown in Figure 5, out of the total 4760 earthquakes in CPTI15, macroseismic parameters were computed
500 for 3009 events and instrumental hypocentres and/or magnitudes for 1901. Both macroseismic and
501 instrumental parameters are available for 721 earthquakes dating as back as 1904 with frequency
502 progressively increasing with time. In addition, because of the absence of either intensity datasets or
503 instrumental data, the parameters of 459 earthquakes, mainly in bordering countries, derived from five
504 parametric catalogues (Postipischl 1985a; ECOS-09, Fäh et al. 2011; Herak 1995; Zivcic 2009; ZAMG 2010) of
505 prevailing macroseismic origin.

506 The macroseismic determination of the epicentre was preferred for earthquakes up to 1984, and the
507 instrumental one for later earthquakes (Figure 6). Several exceptions relate, for example, to earthquakes
508 located at sea or close to the coast, for which the instrumental location is generally selected. The
509 macroseismic location was conversely preferred in areas where the coverage of the seismic network was
510 poor even in the recent past. The choices were made by taking as much as possible into account the reliability
511 of the available data. Macroscopic data of 86 earthquakes in DBMI15 were not considered reliable enough
512 to be parametrized (e.g. those related to aftershocks); additional 26 records correspond to earthquakes for
513 which neither macroseismic nor instrumental data are available, although they are well attested by the
514 reference study.

515 As a whole, the default magnitude is assessed from macroseismic data for 2449 earthquakes (Figure 7).
516 Macroscopic and instrumental magnitude estimates are both available for the same event in 837 cases.
517 Unless the instrumental magnitude strictly derives from a moment tensor inversion, for 571 earthquakes the
518 preferred magnitude is taken as the average of the two values, weighted with the inverse of the square of
519 the associated uncertainties. In such cases, the uncertainty is estimated as the square root of the inverse of
520 the sum of the weights. The default Mw is derived from moment tensor solutions for 619 earthquakes and
521 as a proxy Mw from 869 ones. Figure 8 shows the 1900-2017 timeline for the different magnitude
522 determinations.

For records derived from catalogues of bordering countries, the magnitude is obtained from epicentral intensity through the empirical relation described in eq. (2), except for the Swiss catalogue ECOS-09 (Fäh et al. 2011), from which M_w values and related uncertainties provided by the catalogue were adopted. For 45 earthquakes an epicentral location was available either from instrumental data or from a catalogue, but no magnitude estimates were found in the literature.

The extension of the catalogue from 2006 to the end of 2017, implied the addition to CPTI11 of 452 earthquakes, 39 of which are also supported by intensity data from macroseismic field surveys.

In the common time-period (1000-2006) CPTI11 and CPTI15 contain 3182 and 4298 earthquakes, respectively.

Fifty earthquakes in CPTI11, listed in Online Resource 3, are not anymore in CPTI15 either because they turned out to be fake (32), not supported by reliable data (8), or because of errors in the original data or in the compilation of CPTI11. As a result, CPTI15 contains 1192 more earthquakes than CPTI11. Most of such a difference is due to the lowering of the energy thresholds from intensity 5-6 to 5 and from M_w 4.5 to 4.0, which accounts for the addition of 757 events with respect to CPTI11. The remaining 435 earthquakes, with higher intensity and/or magnitude mostly derive from new historical macroseismic studies (e.g. Camassi et al. 2011; Molin et al. 2008, Castelli et al. 2016; Azzaro and Castelli 2015; Guidoboni and Ciuccarelli 2011), and parametric catalogues (Živčić 2009; Fäh et al. 2011). In addition, 50 deep earthquakes in the Southern Tyrrhenian Sea area, not considered by CPTI11, were added.

The 3129 common earthquakes between CPTI11 and CPTI15 may show considerable differences in both location and magnitude.

As macroseismic epicentres are computed with the same method used for CPTI11, the differences in epicentral location (Figure 9) are mainly related to the updated macroseismic input data. An exception is represented by 21 earthquakes, for which the macroseismic epicentre in CPTI11 was determined with the method by Bakun and Wentworth (1997), and in CPTI15 is substituted by an instrumental determination (4 cases), or a Boxer “method 0” (6) or “method 4” (11) determinations. Other significant differences are due to new instrumental solutions and, to a lesser extent, to the substitution of macroseismic epicentres with instrumental ones.

Apart from the differences in input data, variations in magnitude may be due to the different parameterization of macroseismic magnitudes, to the different conversions of instrumental magnitudes or to a combination of the two.

Figure 10 shows the M_w differences between CPTI15 and CPTI11, according to the M_w determination in CPTI15 (left panel: mean, from the method of circles, from epicentral intensity; right: observed true or proxy M_w).

As a general trend, M_w values in CPTI15 are lower than those in CPTI11, especially for small earthquakes. As for macroseismic magnitudes, the effect of the many (882) values now derived from MDPs is evident in their

distribution over wide magnitude ranges instead of their clustering around values obtained from the linear $\log_{10}N$ - M relationship. Macroseismic determinations also account for the variations observed for high magnitudes. Such differences are due to the substitution of some solutions from the method by Bakun and Wentworth (1997) for large offshore earthquakes with determinations by Boxer (homogeneous with the rest of the catalogue), or to the new intensity distributions, sometimes remarkably different from previous ones. Significant variations, again mainly towards low values, derive also from the adoption of the solutions proposed by the new Swiss catalogue ECOS-09 (Fäh et al. 2011), which is updated with respect to the version ECOS-02 considered by CPTI11.

Instrumental magnitudes higher than 5.5 are substantially equivalent in the two catalogues, probably as a result of the few changes in the considered magnitude type for large earthquakes. For low magnitude values, some differences are present, especially as far as proxy M_w are concerned. This probably results from the new harmonization and combination criteria adopted. Differences in low values of M_w from moment tensor solutions are due to the corresponding datasets, previously not considered.

6. Frequency magnitude distribution and completeness

It is well known that the number N of earthquakes occurring in a given area within a given interval of time follows the power law as a function of magnitude M first proposed by Gutenberg and Richter (1944) (hereafter GR)

$$\log_{10}N = a - bM \quad (4)$$

in which a is related to the seismic productivity of the considered area and depends on spatial and temporal coverage of the earthquake catalogue, and b (b -value) is an index of the relative proportion between large and small earthquakes. The general validity of the GR law has been tested by a number of studies concerning different regions of the world, although small deviations of b -value from the average value 1 have been observed and related to the state of stress of the region (e.g. Schorlemmer et al. 2005; Scholz 2015, Petrucci et al. 2018). Significant deviations from the linear behaviour of eq. (4) are usually observed at large and small magnitudes and are explained by physical spatial limits of the dimension of the seismogenic fault and by the incompleteness of small earthquakes recording due to the limited sensitivity of the seismometric network, respectively.

The assessment of the magnitude threshold of completeness of an earthquake catalogue is of fundamental importance for any statistical analysis of seismicity, and for seismic hazard assessment. The completeness of a catalogue for which the sensitivity of the network detection is constant with time is usually evaluated just observing the point below which the frequency-magnitude distribution of earthquakes deviates from the linear law (see Woessner and Wiemer 2005, for a thorough overview). If instead the sensitivity of the detection network changes (usually increases) with time a combined analysis of the GR and of the cumulative plot of the number of earthquakes with time has to be made (see e. g. Mulargia et al. 1987).

592 In the case of CPTI15, which spans in time more than 10 centuries, the concept of detection network has to
593 be intended in a broader sense than a modern seismometric network, available only since the end of XIX
594 century. In this context, the detection network concerns the presence (or absence) over the territory of
595 cultural centres where the information on earthquake effects was recorded and preserved over time (see
596 Stucchi et al. 2004).

597 To assess the overall completeness of CPTI15, we analyze the cumulative plots of the numbers of earthquakes
598 above different magnitude thresholds at 0.5 intervals, from the nominal minimum magnitude of the
599 catalogue ($M_w \geq 4.0$) to the maximum possible threshold ($M_w \geq 7.0$). The visual analysis of the cumulative plot
600 for $M_w \geq 4.0$ (Fig. ES1 of Online Resource 4) indicates that the present rate of about 30 earthquakes per year
601 was reached only in 1975. This date actually represents a milestone in the evolution of the Italian
602 seismometric network because at about that time ING (today INGV) started to locate earthquakes using
603 computer codes minimizing the sum of squares of arrival times residuals and to compute magnitudes using
604 standard Wood-Anderson seismometers. For $M_w \geq 4.5$ (Fig. ES2 of Online Resource 4) the cumulative plot
605 indicates that the present rate of about 8 shocks per year was reached around 1880. Even in this case, we
606 can relate the date with a significant improvement of the detection capability because at about that time a
607 dense network of observatories and meteorological stations, in some cases also equipped with the first
608 mechanical seismometers, became operational over the entire Italian territory. With the establishment, in
609 1887, of the Geodynamic Service within the Central Office of Meteorology, the practice of collecting news on
610 the effects of earthquakes through questionnaires ("macroseismic cards") became systematic, a practice
611 further developed with the birth, in 1895, of the Italian Seismological Society (see Camassi 1991; Ferrari 1992;
612 Molin et al. 2008). Even for $M_w \geq 5.0$ (Fig. ES3 of Online Resource 4) the present rate of about 2.5 earthquakes
613 per year seems to be reached around 1880. The present rate (Fig. ES4 of Online Resource 4) of about one
614 $M_w \geq 5.5$ shock every two years can be observed from 1780 on. Such an improvement should refer to the
615 ability to record information on the macroseismic effects of earthquakes. The occurrence, in the second half
616 of the 18th century, of a series of large earthquakes (the great 1783 Calabrian earthquakes, together with
617 the long seismic sequences that shook central Italy in the second half of the 18th century) resulted in a strong
618 increase in sensitivity to earthquakes, also linked to a scientific interest related to the development of new
619 theories about their origin. This growth of attention stimulates the proliferation of collections of news about
620 earthquakes, also favoured by the development of the European journalistic networks (Camassi and Castelli
621 2004; 2005). For $M_w \geq 6.0$ (Fig. ES5 of Online Resource 4) a clear change in the slope of the cumulative plot
622 toward the present rate of about one earthquake every 6 years can be observed around 1620. The
623 explanation of this abrupt improvement of the information available on earthquakes might refer in general
624 to the increase of interest on scientific phenomena starting from the beginning of the 17th century. This was
625 accompanied by the growth of the Italian and European journalistic network (handwritten "avvisi" and
626 printed gazettes), which allowed an efficient circulation of news, later collected in the 19th century

627 seismological compilations (Camassi and Castelli, 2004; 2005). Even for the other thresholds $M_w \geq 6.5$ and
628 $M_w \geq 7.0$ (Fig. ES6 and ES7 of Online Resource 4, respectively) the slope change to the present rates of about
629 one earthquake every 13 and 50 years respectively appears to have occurred around 1620.
630 Assuming the above-mentioned completeness intervals (since 1975 for $M_w \geq 4.0$, since 1880 for $M_w \geq 4.5$,
631 since 1780 for $M_w \geq 5.5$, and since 1620 for $M_w \geq 6.0$), we computed the b-value in each of them with the
632 method by Aki (1965), obtaining 1.01 ± 0.03 , 1.05 ± 0.03 , 1.06 ± 0.09 and 0.94 ± 0.11 respectively. These values
633 indicate a rather good consistency of the frequency magnitude distribution with the global average b-value
634 (H1) and among the different time intervals. Even the productivity coefficient (a -value) is rather consistent
635 among different completeness intervals, as demonstrated in Figure 11 where the frequency magnitude
636 distributions, normalized for the duration of each completeness interval, are superimposed. The only notable
637 discrepancy concerns magnitudes around 5.5, for which the shorter time interval shows slightly larger rates
638 than longer intervals. The abrupt decrease of all the rates for $M_w \geq 7.1$ indicates that such magnitude probably
639 represents an upper limit in most of the seismogenic areas of Italy. The only earthquake with larger
640 magnitude ($M_w = 7.3$) is that one occurred in Eastern Sicily on 11 January 1693.

641 **7. Website**

642 CPTI15 and the related macroseismic database DBMI15 are publicly available on a dedicated and specifically
643 developed website, as all their previous versions and predecessors back to the NT4.1 catalogue (Camassi and
644 Stucchi 1997) and DOM macroseismic database (Monachesi and Stucchi 1997).
645 The CPTI15-DBMI15 website (<https://emidius.mi.ingv.it/CPTI15-DBMI15/>), available in English and Italian,
646 allows querying CPTI15 by earthquake, and retrieving all the events in a table with the earthquake date, the
647 epicentral area, the number of macroseismic intensity data points (if any), the epicentral intensity, and the
648 moment magnitude. Earthquakes' epicentres are also plotted on a map that can be panned and zoomed, and
649 the symbol representing the epicentre can be clicked to obtain more details on the selected event. Once an
650 earthquake is selected, the user is presented with a series of additional information, such as the macroseismic
651 and/or instrumental parameters, the source of the macroseismic intensity data, and the list of macroseismic
652 intensities (with place name, coordinates and intensity), depending on their availability. In addition, a
653 permalink directly points to the downloadable Microsoft Excel (.xlsx) and Comma Separated Value (.csv)
654 catalogue files. Another link gives access to all the additional data related to the earthquake archived in the
655 Italian Archive of Historical Earthquake Data ASMI (see Section 3), such as earthquake parameters provided
656 in other parametric catalogues, the information contained in the selected study, and the list of alternative
657 studies related to the same earthquake.
658 Users may apply a filter to the list of earthquakes based on one or more parameters of their choice, either
659 year, number of macroseismic intensity data points, epicentral intensity or magnitude. A circular or polygonal
660 geographical selection is also possible by either drawing the area of interest directly on the map, or by

661 entering the coordinates of the vertices for a more precise selection. To simplify the reproduction of the
662 same geographical selection later on, the user can copy and paste the entered parameters, i.e the list of
663 coordinates representing the vertices of the polygon, and then paste it for re-creating the same selection
664 polygon.

665 Macroseismic intensity data can be queried by searching a place name, in alphabetical order, by geographical
666 selection on the map, or by an administrative subdivision, either region, province or municipality. Once the
667 user selects a place, the list of all the earthquakes that were recorded as a macroseismic effect at the place
668 itself is provided.

669 The table of CPTI15 can be downloaded in two formats, for Microsoft Excel (.xls), and as an Open Document
670 Format for Office Applications (.odf). The spreadsheet contains three sheets presenting: a) the content and
671 few other useful information, such as the list of the authors, the terms of use and the bibliographical citation,
672 b) the description of each field, and c) the catalogue table itself.

673 The website is created using an updated version of the open-source web application called MIDOP (Locati
674 and Cassera 2010), developed in-house. MIDOP, the Macroseismic Intensity Data Online Publisher, was
675 originally meant for publishing Italian intensity data that are periodically updated at each new release of
676 DBMI. Since 2012, in the framework of AHEAD, the European Archive of Historical Earthquake Data (Locati
677 et al. 2014; Rovida and Locati 2015), MIDOP has been extended to allow the publication of intensity data in
678 other European, then worldwide geographical areas. MIDOP is presently in use at the British Geological
679 Survey (BGS), the Institut Cartogràfic i Geològic de Catalunya (ICGC), the University of Athens (UoA), the
680 Instituto Geográfico Nacional (IGN), and is currently being tested at the Earth Observatory of Singapore (EOS)
681 and the University of Bergen (UiB).

682 In addition to the user-friendly website and the downloadable spreadsheet, CPTI15 can be accessed using
683 two distinct types of web services. The first type is a FDSN-event web service, a standard proposed by the
684 Federation of Digital Seismograph Networks for exchanging earthquake parameters using a simple RESTful
685 interface, which provides users with the possibility of sending a complex query based on a series of
686 parameters that can be freely combined together. Examples of available query parameters are the minimum
687 or maximum magnitude, a time-range, a circular or rectangular geographical area, and the desired output
688 format. The standard FDSN-event service should support at least two output formats: a compact and simple
689 plain text (.csv) with the most relevant parameters, such as epicentral location and magnitude, and the more
690 complex QuakeML (Schorlemmer et al. 2011), an XML based format which is able to associate multiple
691 epicentral and magnitude estimations to an earthquake.

692 The second type of web services are compliant with OGC (Open Geospatial Consortium), a general-purpose
693 standard meant to transfer geographical information across the web using platform-independent calls. The
694 WFS (Web Feature Services) are able to output the original geographical features together with the
695 associated parameters, and the WMS (Web Map Service) is able to output georeferenced map images where

696 the features are represented with a pre-configured set of symbols. In the case of CPTI15 the output features
697 are points representing the epicentres, to which the list of CPTI15 parameters is associated. The general-
698 purpose nature and the widespread use of the OGC standard web services enable the user to directly load
699 CPTI15 in any OGC compliant software, most notably the Open Source QGIS and ESRI GIS products, such as
700 the ArcGIS in both the desktop and online versions.

701 **8. Conclusions**

702 The most recent version (2.0) the Parametric Catalogue of Italian Earthquakes CPTI15 represents the latest
703 step in the evolution of the Italian tradition and experience in earthquake cataloguing. Such a tradition began
704 45 years ago, as far as modern parametric catalogues are concerned, but it may date back to the long history
705 of compiling earthquake data and information started in Italy in the late 19th century.

706 Even with respect to the previous version CPTI11, released in 2011, the changes and improvements of CPTI15
707 are many. Changes mainly deal with the update of the input macroseismic data, deriving from the great
708 improvement in terms of both the number and the quality of the historical macroseismic investigations that
709 have been performed in Italy in the last few years, as well as with the refinement in the procedures related
710 to magnitude acquisition, conversion and harmonization. The latter particularly affected the low magnitudes,
711 the assessment of which is now much more robust than before. In general, a great effort aimed at
712 harmonizing magnitude estimates of various origin and periods. This concerned, on the one hand, the
713 harmonization of instrumental and macroseismic magnitudes, and on the other hand the conversion of
714 magnitudes from different origins, methods and scales to modern moment magnitude from the inversion of
715 moment tensors. In the compilation, published and peer-reviewed data and procedures are used as much as
716 possible and are fully coded in the catalogue file. In addition to the website specifically developed to consult
717 and access the catalogue, the input macroseismic data and the studies they derive from are collected and
718 fully accessible through dedicated databases and web portals, namely the Italian Macroseismic Database
719 DBMI15, and the Archive of Italian Historical Earthquake Data ASMI.

720 The analysis of the cumulative number of earthquakes above different magnitude thresholds indicates that
721 CPTI15 is complete since 1975 for $M_w \geq 4.0$, since 1880 for $M_w \geq 4.5$, since 1780 for $M_w \geq 5.5$, and since 1620
722 for $M_w \geq 6.0$. Unlike previous catalogues of Italian seismicity, the frequency magnitude distribution obtained
723 from CPTI15 for this different completeness time intervals presents a b-value ≈ 1 , consistent with the global
724 average and current instrumental catalogues. For this reasons CPTI15 is suitable for robust statistical analyses
725 of the time-space property of Italian seismicity.

726 In spite of the mentioned features and the considerable step forward it represents, CPTI15 cannot be taken
727 as a point of arrival, since many enhancements are possible and some issues are still to be faced. The legacy
728 of the late 19th-century seismological compilations is still important, resulting in the possibility of finding
729 data on unknown earthquakes in historical sources and archives that have not been fully exploited so far.

730 This possibly results also in a spatial and/or temporal inhomogeneity of the catalogue, depending on the
731 areas and/or periods that have been the object of subsequent specific research, none of which has ever been
732 aimed at a homogeneous revision of the earthquake catalogue at the national scale. In addition, historical
733 investigations of the past mostly focused on the strongest earthquakes, sometimes neglecting the definition
734 of minor seismicity, equally important in many applications. Another possible inhomogeneity concerns the
735 representation of seismic sequences, which is particularly important in most of the areas of the Italian
736 Apennines. This is a consequence of both the objective difficulty (or impossibility) of discriminating single
737 shocks in a sequence from the point of view of their macroseismic effects, and, again, of the legacy of past
738 studies that sometimes did not dedicate sufficient attention to such a problem.

739 The procedure established and followed in the compilation of the catalogues of the CPTI family ensures the
740 easy and rapid incorporation of new and fresh data. Future releases will take into account all the wealth of
741 data that hopefully will become available in the future, for a more and more robust and thorough knowledge
742 of the past Italian seismicity.

974 Tables

975 **Tab. 1** List of the national and regional parametric catalogues contributing to the PFG catalogue (Postpischl 1985a),
976 together with their spatial coverages, number of entries, and reference code

Reference	Code	Region	Entries
ENEL (1977)	000	Italy	16,117
Iaccarino and Molin (1978)	501	North-Eastern Italy	1,725
Dell'Olio and Molin (1980)	502	Lazio	5,511
Magri and Molin (1979)	503	Basilicata	553
Bernardis et al. (1977)	504	Friuli	1,664
Bernardis et al. (1978)	505	Friuli	134
Eva et al. (1978)	506	Liguria	778
Carrozzo et al. (1975)	507	Calabria and Sicily	7,633
ING Seismic Bulletin (1976-1980)	226	Italy	2,735

977

978 **Tab. 2** List of non-conventional descriptive codes, their meaning, associated numerical value, and the corresponding
979 number of MDPs reported in DBMI15

Code	Description	Ass. value	MDPs
HD	Heavy Damage	8.6	189
D	Damage	6.4	707
SD	Slight Damage	5.6	31
HF	Highly Felt	5.1	112
F	Felt	3.9	5400
SF	Slightly Felt	2.9	49
NC	Not Classified	1.8	131
NF	Not Felt	1	24028
G	Generic damage information	0.2	5

980

981 **Tab. 3** List of the large uncertain intensities and their corresponding translation in the best-matching non-conventional
982 intensities

Greatly uncertain intensity	Non-conventional descriptive codes	MDPs
8-10	HD	1
≥ 7	HD	18
7-9	HD	7
6-8	D	55
5-7	D	7
3-5	HF	44
2-5	F	47
2-4	SF	34

983 **Tab. 4** Recompile criteria adopted for the homogenization of the original intensities

991 **Tab. 6** Recalibrated coefficients (*a,b,c*), standard deviations of regressions (*s*), weight normalization factors (*K*) and
992 degrees of freedom (*df*) for computation of macroseismic magnitude with the Boxer program.

Intensity	a	b	c	s	K	df
2	3.12202	0.04414	0.02241	0.2611	10.4	82
2-3	3.01875	0.04769	0.02309	0.1805	10.7	43
3	2.94284	0.05239	0.02345	0.2482	17.9	211
3-4	2.89718	0.05662	0.02400	0.2194	16.4	139
F (3.9)	3.60901	0.02733	0.02374	0.2017	14.0	22
4	3.20351	0.05107	0.02218	0.2413	23.0	224
4-5	3.16818	0.04417	0.02667	0.2390	20.1	134
5	3.69208	0.02425	0.02462	0.2433	27.1	118

995

996 **Figure captions**

997 **Fig. 1** Map of the earthquakes in CPTI15. The solid blue line indicates the boundary of the area covered by
998 the catalogue. Earthquakes of CPTI11 relocated outside the area are maintained in CPTI15

999 **Fig. 2** Scheme used in the compilation of the catalogue and the relationships among input data, ASMI,
1000 DBMI15, and CPTI15

1001 **Fig. 3** a) Magnitude and b) intensity distributions in the dataset used for calibrating Boxer

1002 **Fig. 4** Comparison between the observed (instrumental) Mobs and calculated (macroseismic) magnitude
1003 values Mcalc for the 354 calibrating events. a) The grey line indicates the equality between the two estimates.
1004 b) The black line indicates the frequencies of a Normal distribution with average -0.08 and standard deviation
1005 0.40

1006 **Fig. 5** Type of default epicentral location in CPTI15. MI = macroseismic (alternative to instrumental); IM =
1007 instrumental (alternative to macroseismic); II = instrumental (only option); MM = macroseismic (only option);
1008 PC = from parametric catalogue; NP = not determined

1009 **Fig. 6** Data availability and selected locations in four different time-windows in the 20th century. II =
1010 exclusively instrumental; MI = macroseismic alternative to instrumental; IM = instrumental alternative to
1011 macroseismic; MM = exclusively macroseismic.

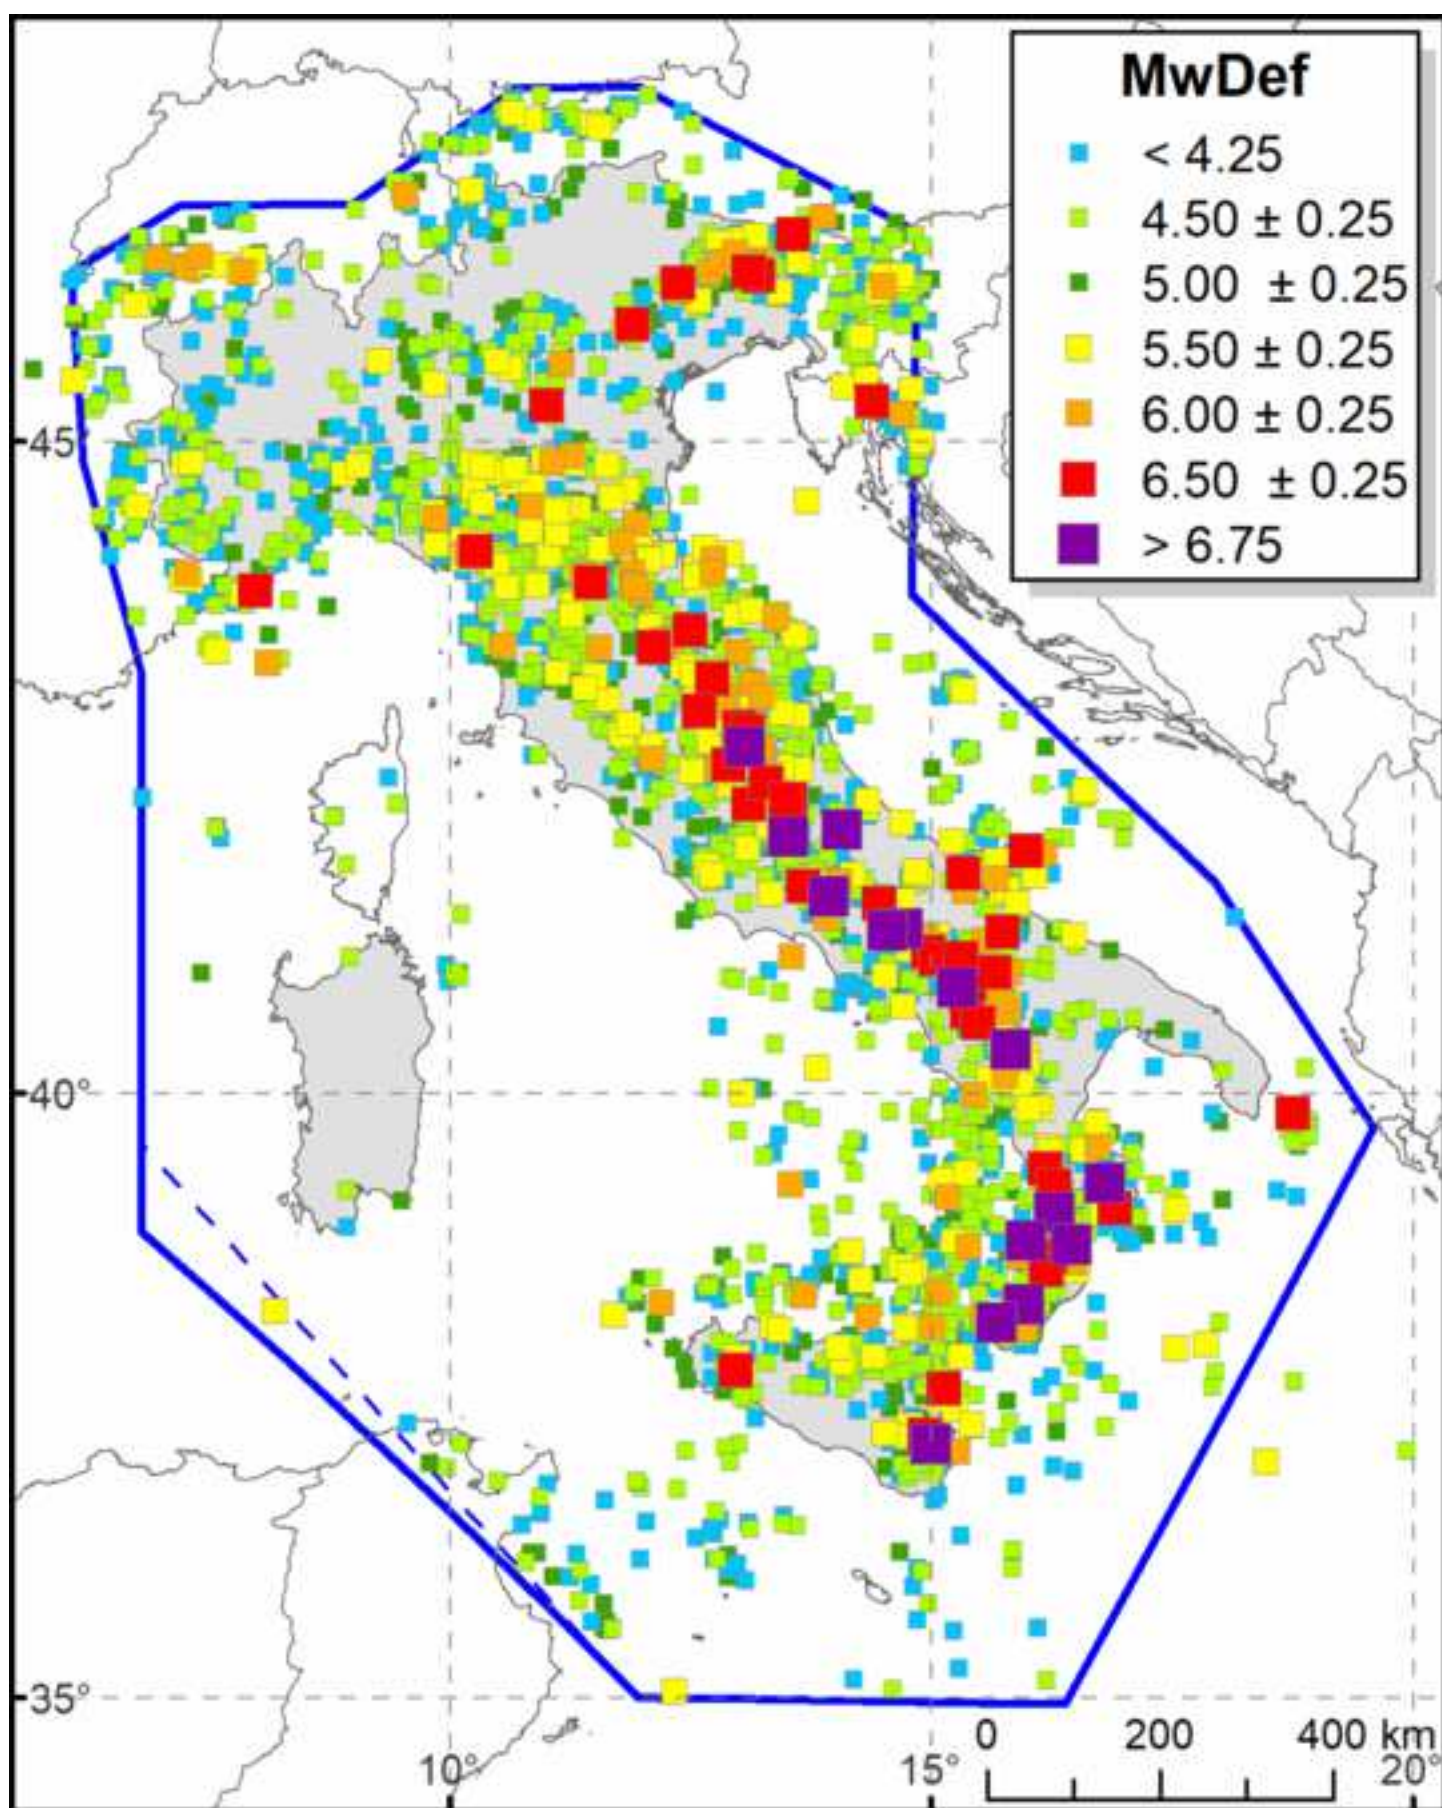

1012 **Fig. 7** Types of default magnitude in CPTI15 (InsO = instrumental "genuine" Mw; InsC = proxy instrumental
1013 Mw; Mdm = macroseismic, from intensity data; Mlo = macroseismic, from epicentral intensity; Mpc = from
1014 another parametric catalogue; Wmim = mean of macroseismic and instrumental values; NP = not
1015 parametrized)

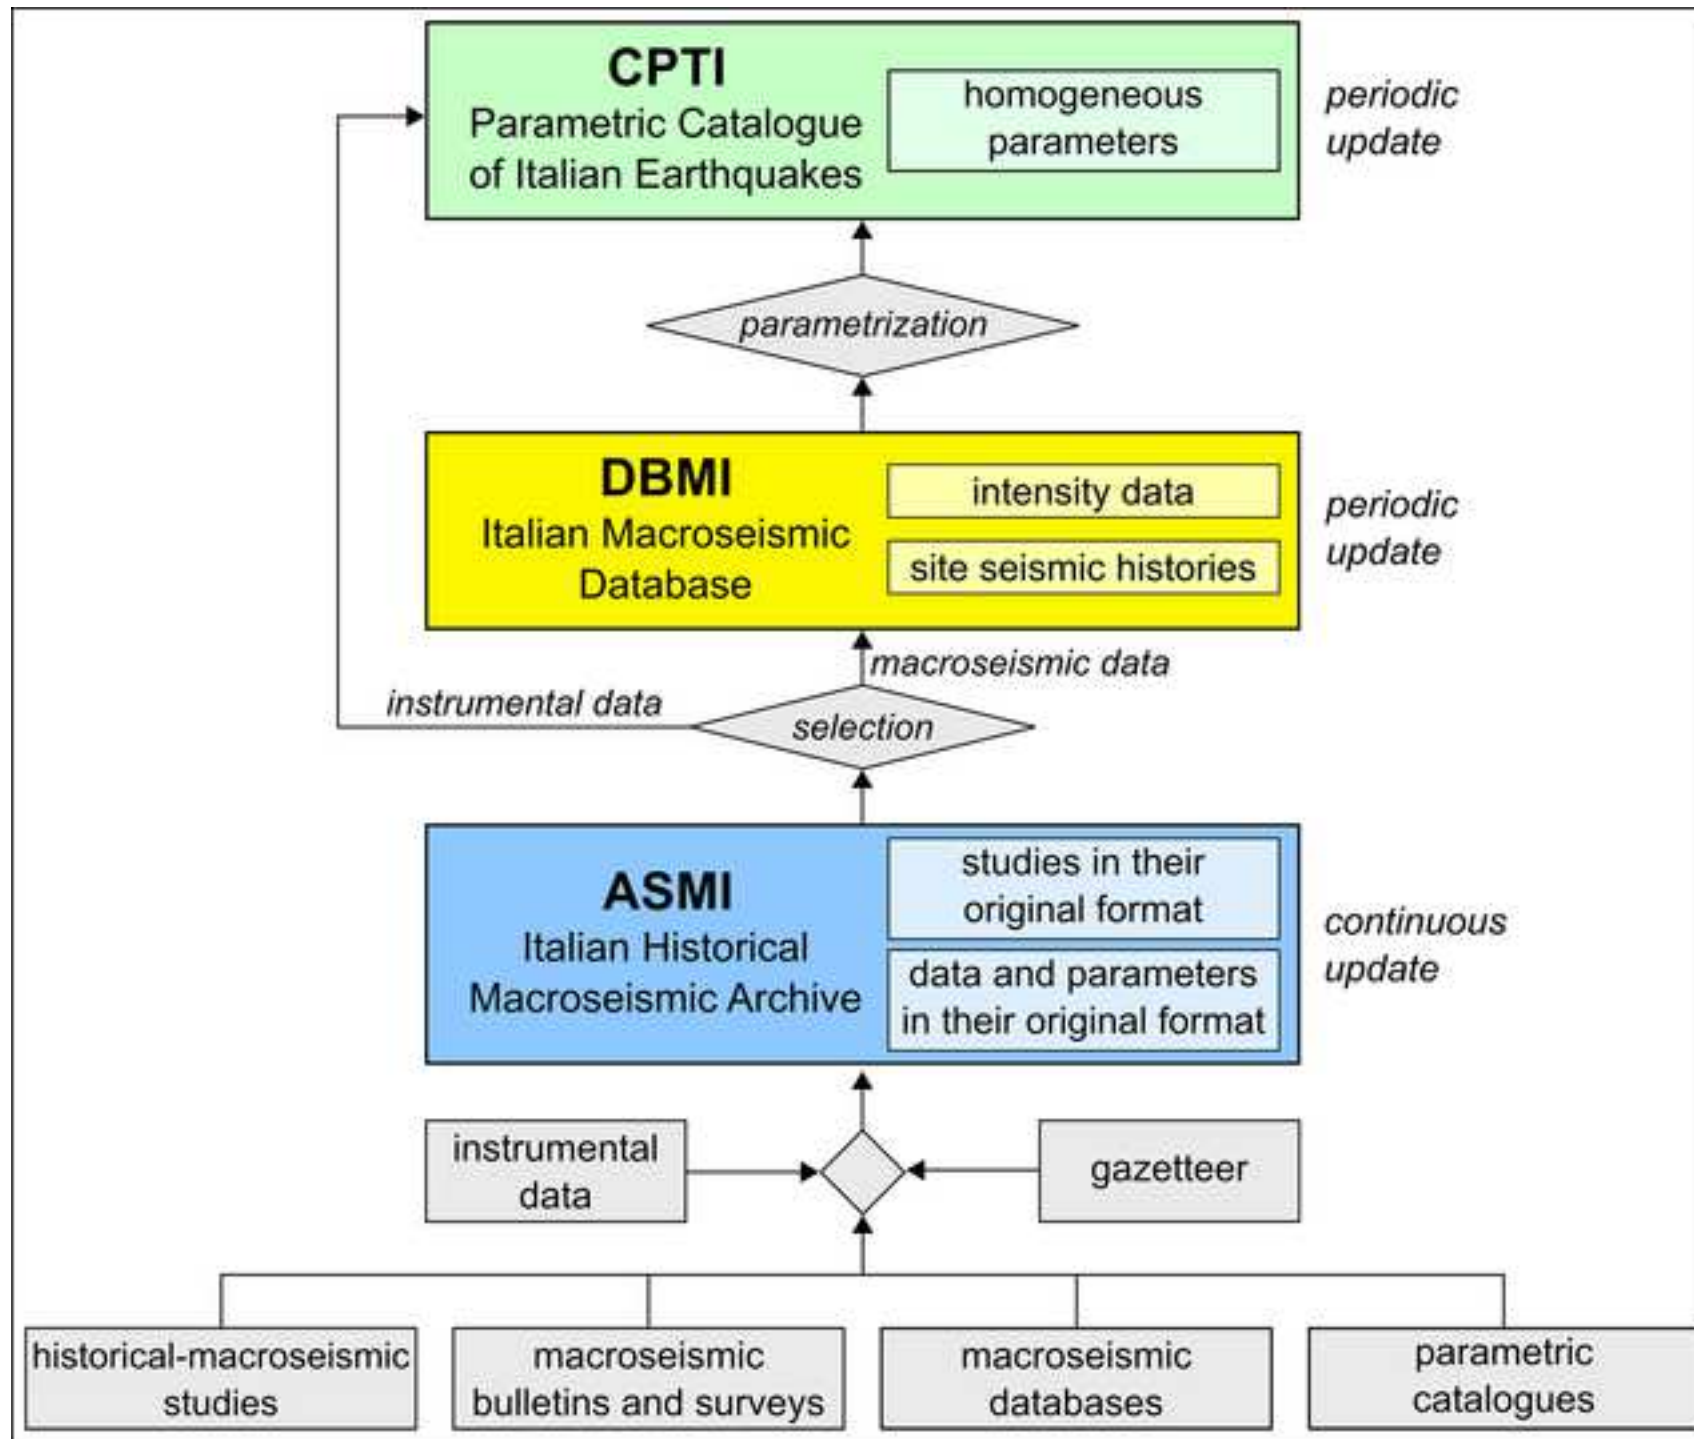

1016 **Fig. 8** Timeline (1900 - 2017) for the different magnitude determinations

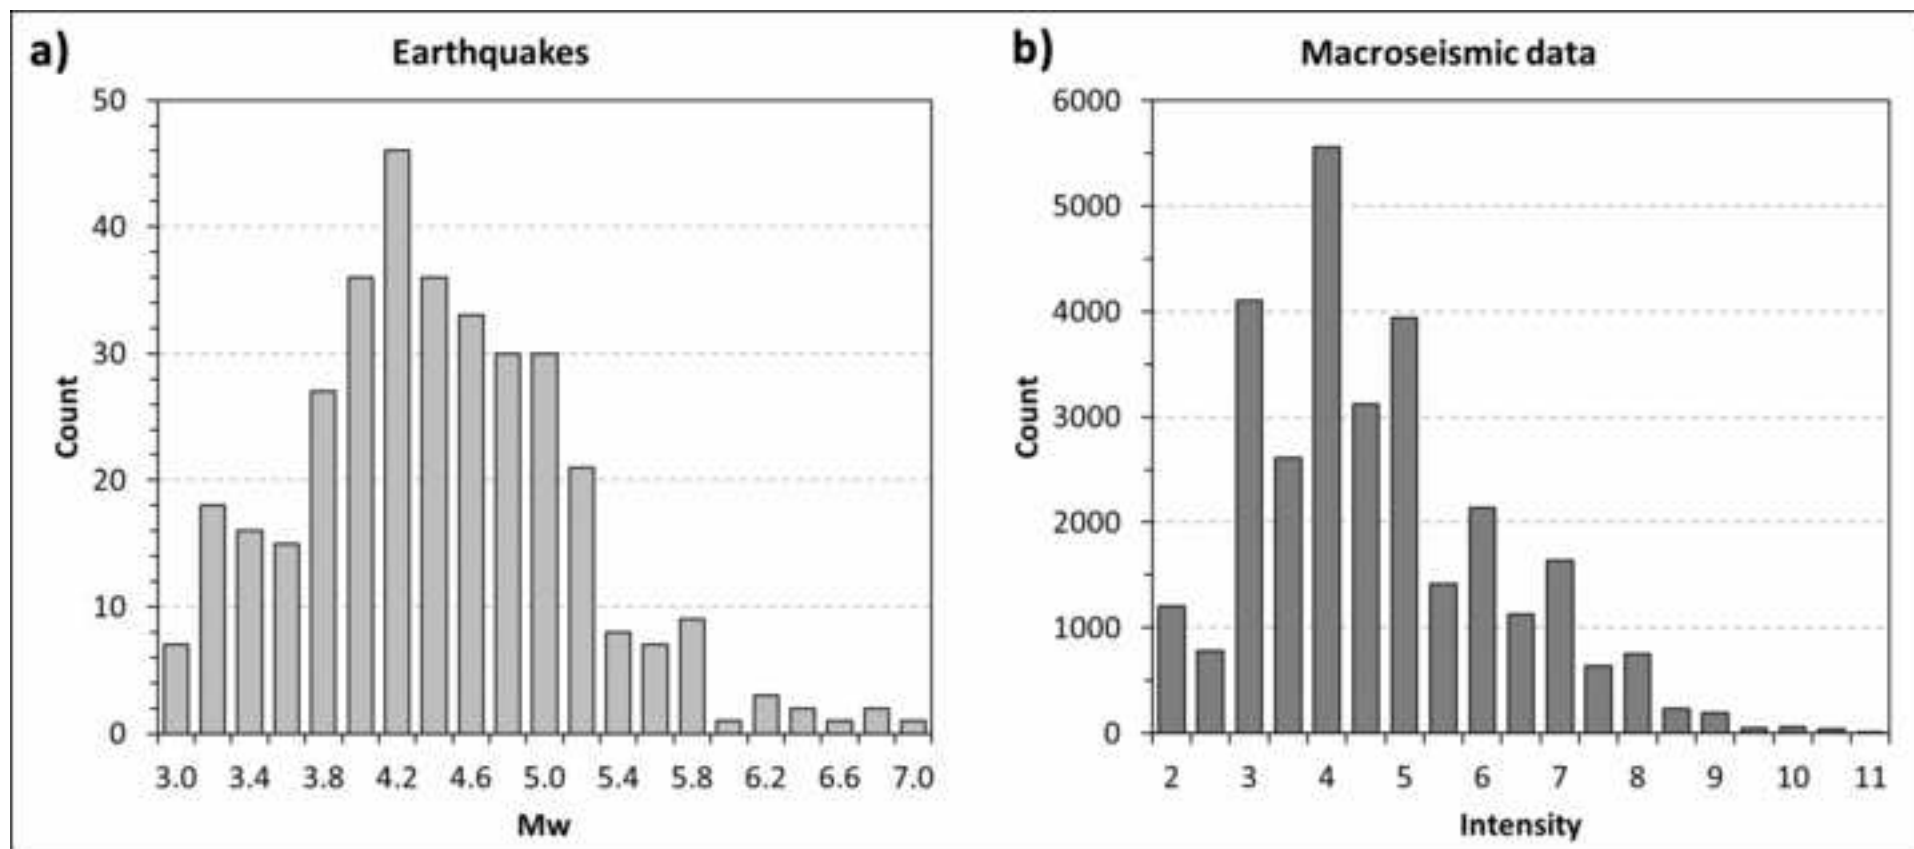

1017 **Fig. 9** Main differences between the epicentral locations (≥ 30 km) in CPTI15 (coloured squares) and in CPTI11
1018 (black dots)

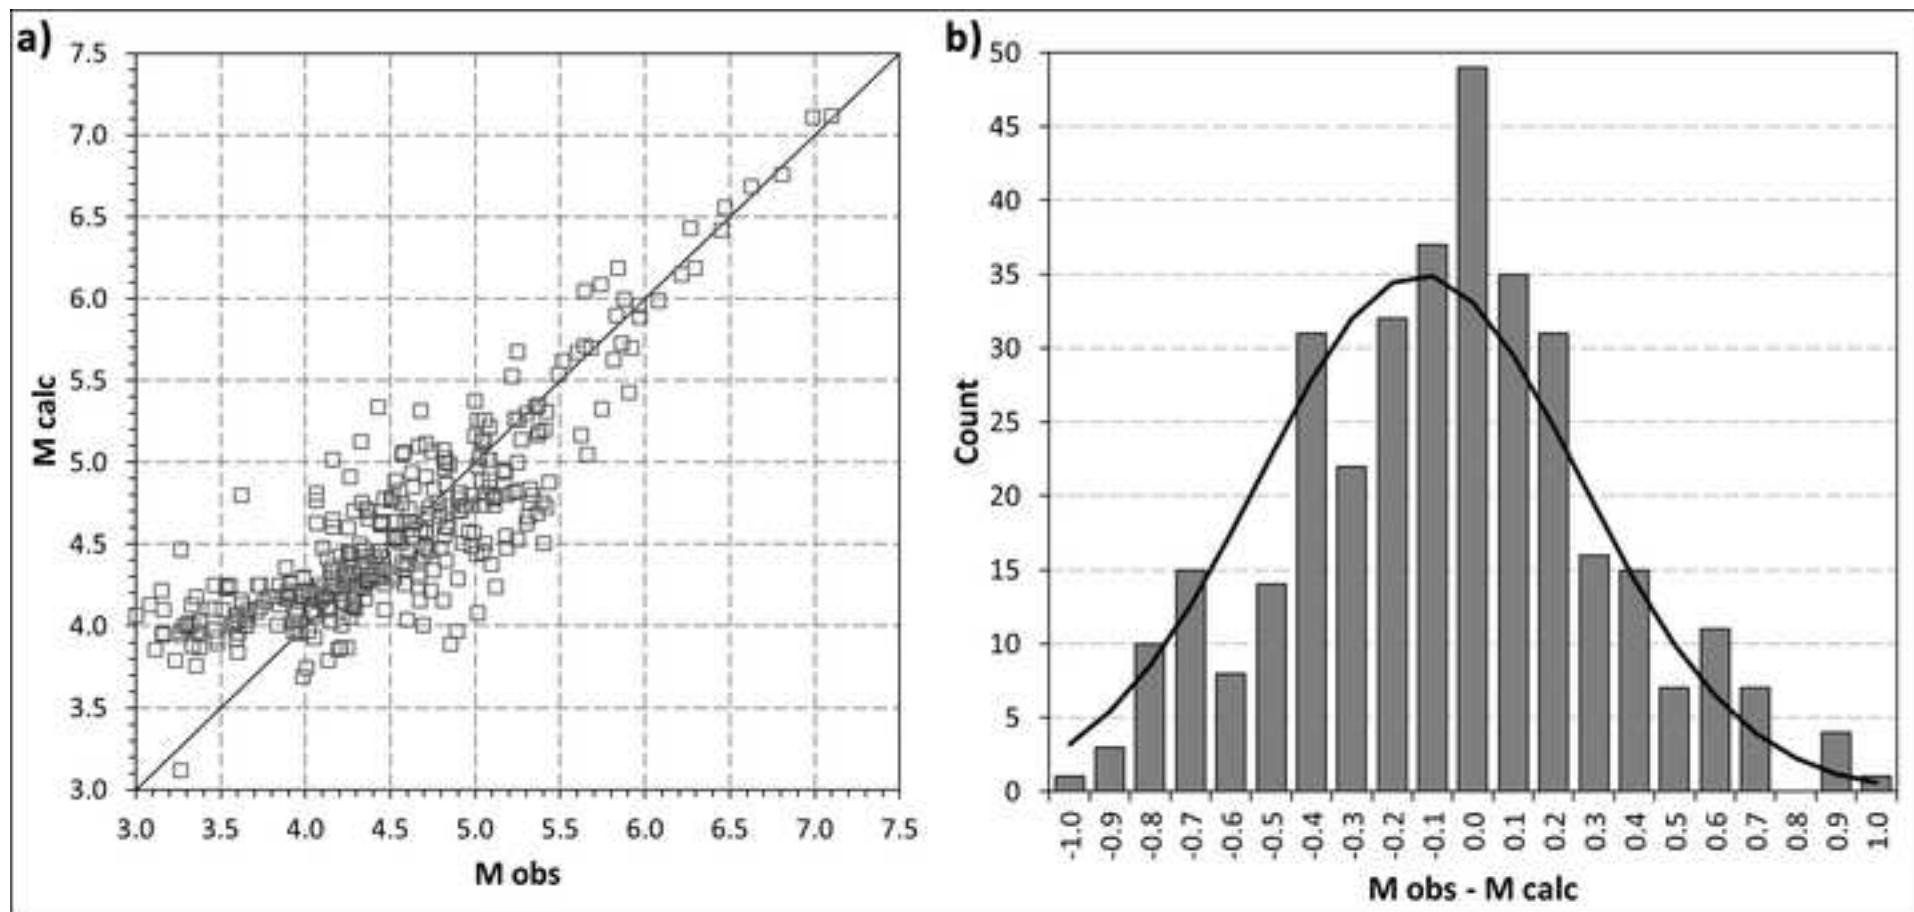

1019 **Fig. 10** Comparison between CPTI15 and CPTI11 magnitudes. Magnitudes are shown according to their type
1020 in CPTI15. Left: Wmim = mean of instrumental and macroseismic determinations; Mdm = macroseismic, from
1021 intensity data; Mlo = macroseismic, from epicentral intensity; Mpc = from parametric catalogue. Right: InsO
1022 = instrumental, Mw from moment tensor solutions; InsC = instrumental proxy Mw

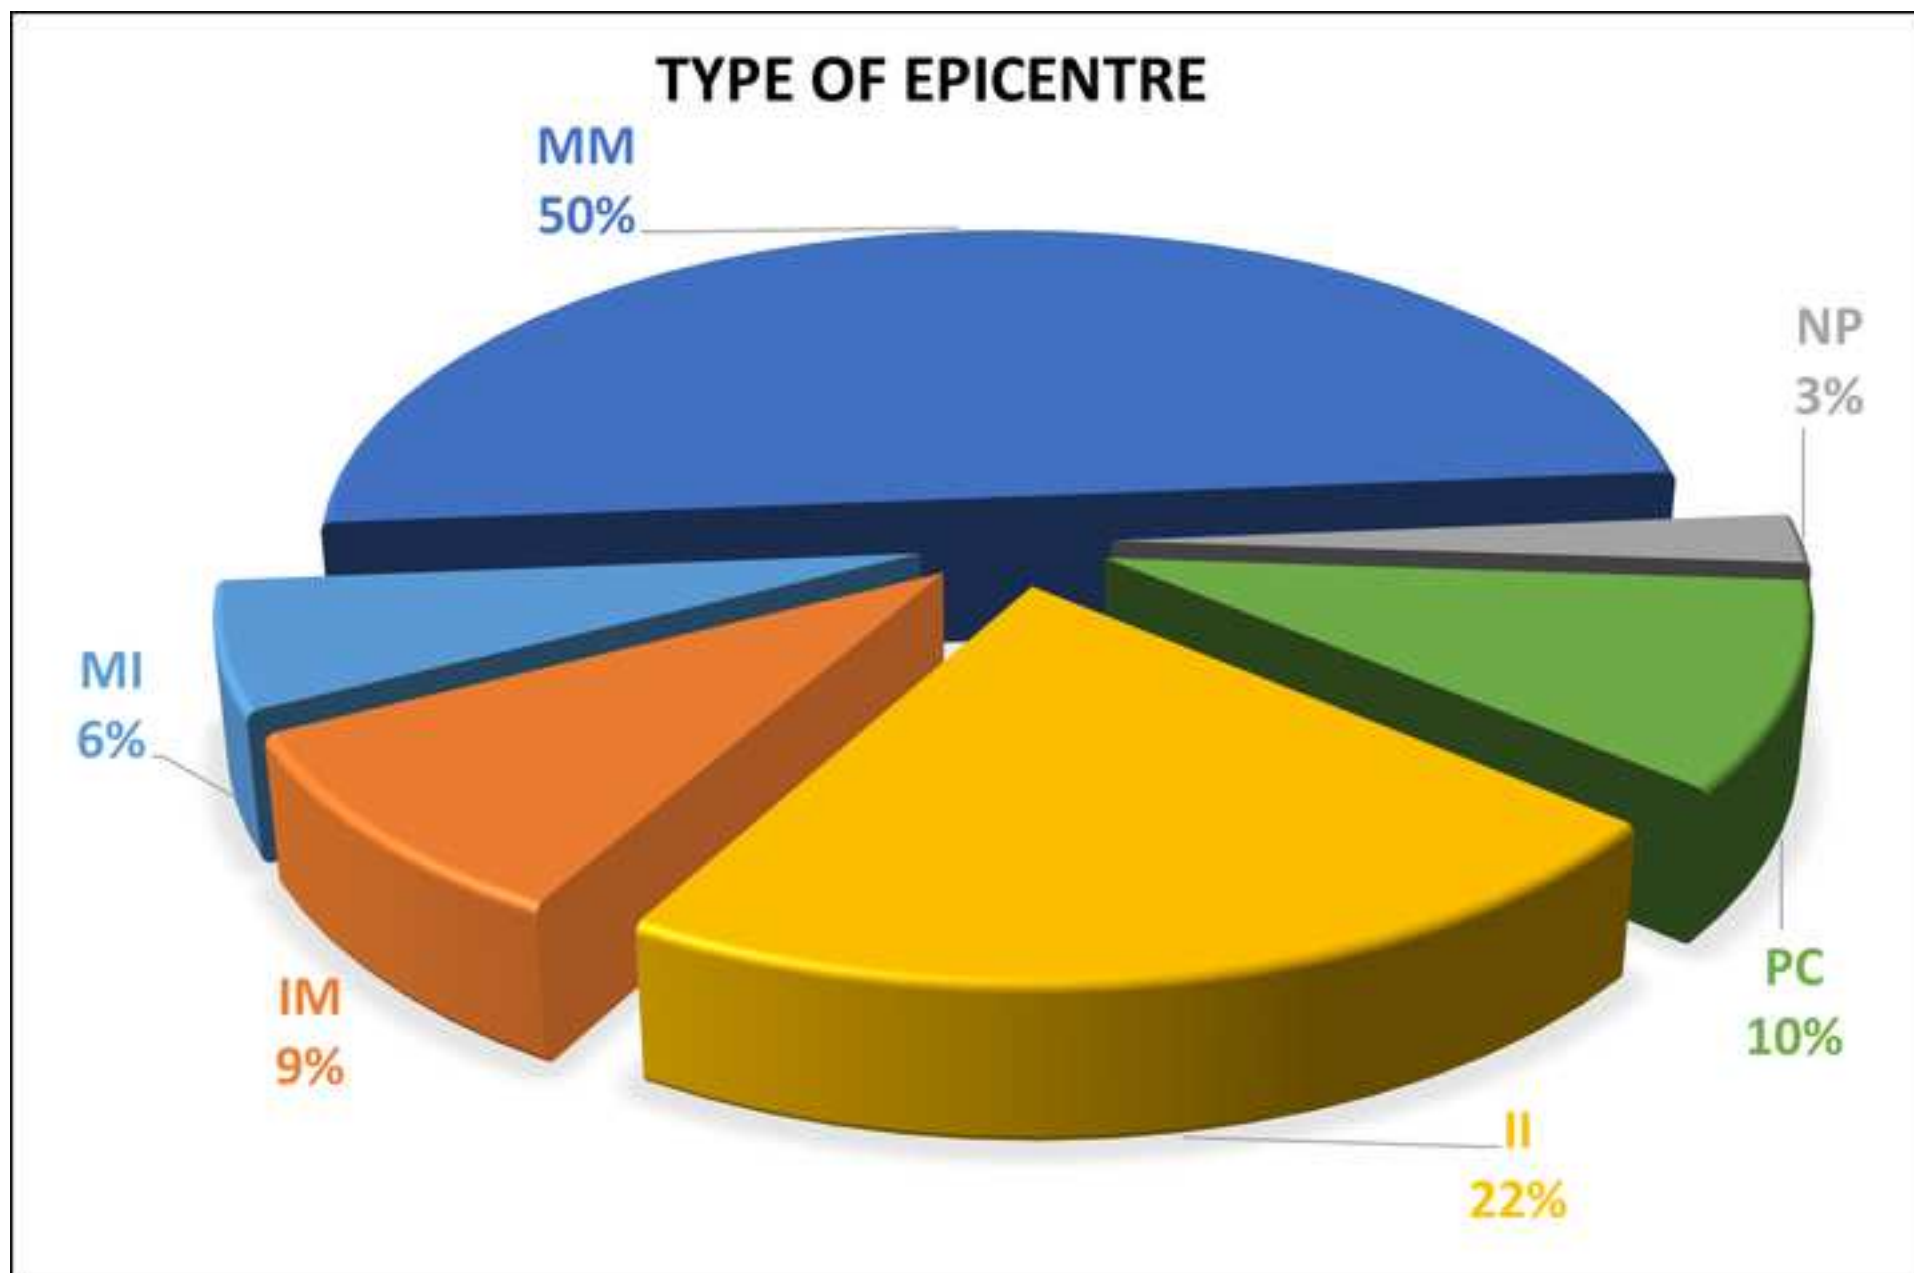

1023 **Fig. 11** Frequency-magnitude distribution (cumulative) of earthquakes in the catalogue for different time
1024 intervals and magnitude thresholds.
