Short Codes for Quantum Channels with One Prevalent Pauli Error Type

Marco Chiani, *Fellow, IEEE*, and Lorenzo Valentini

Abstract—One of the main problems in quantum information systems is the presence of errors due to noise, and for this reason quantum error-correcting codes (QECCs) play a key role. While most of the known codes are designed for correcting generic errors, i.e., errors represented by arbitrary combinations of Pauli X , Y and Z operators, in this paper we investigate the design of stabilizer QECC able to correct a given number e_g of generic Pauli errors, plus e_z Pauli errors of a specified type, e.g., Z errors. These codes can be of interest when the quantum channel is asymmetric in that some types of error occur more frequently than others. We first derive a generalized quantum Hamming bound for such codes, then propose a design methodology based on syndrome assignments. For example, we found a $[[9, 1]]$ quantum error-correcting code able to correct up to one generic qubit error plus one Z error in arbitrary positions. This, according to the generalized quantum Hamming bound, is the shortest code with the specified error correction capability. Finally, we evaluate analytically the performance of the new codes over asymmetric channels.

Index Terms—Quantum Information, Quantum Error Correction, Quantum Hamming Bound, Asymmetric Quantum Channels.

I. INTRODUCTION

The possibility to exploit the unique features of quantum mechanics is paving the way to new approaches for acquiring, processing and transmitting information [1]–[5]. In this regard, one of the main problems is the noise caused by unwanted interaction of the quantum information with the environment. Error correction techniques are therefore essential for quantum computation, quantum memories and quantum communication systems [6]–[9]. Compared to the classical case, quantum error correction is made more difficult by the laws of quantum mechanics which imply that qubits cannot be copied or measured without perturbing state superposition [10]. Moreover, there is continuum of errors that could occur on a qubit. However, it has been shown that in order to correct an arbitrary qubit error it is sufficient to consider error correction on the discrete set of Pauli operators, i.e., the bit flip X , phase flip Z , and combined bit-phase flip Y [6], [11]–[13]. Hence, we can consider in general a channel introducing qubit errors X , Y , and Z with

probabilities p_X , p_Y , and p_Z , respectively, and leaving the qubit intact with probability $1 - \rho$, where $\rho = p_X + p_Y + p_Z$. A special case of this model is the so-called depolarizing channel for which $p_X = p_Y = p_Z = \rho/3$. Quantum error-correcting codes for this channel are thus naturally designed to protect against equiprobable Pauli errors [14]–[16].

However, not all channels exhibit this symmetric behaviour of Pauli errors as, in some situations, some types of error are more likely than others [17]. In fact, depending on the technology adopted for the system implementation, the different types of Pauli error can have quite different probabilities of occurrence, leading to asymmetric quantum channels [18]–[20].

Owing to this considerations, it can be useful to investigate the design of quantum codes with error correction capabilities tailored to specific channel models. For example, codes for the amplitude damping channel have been proposed in [21]–[26], while quantum error-correcting codes for more general asymmetric channels are investigated in [17]–[19], [27]. In particular, asymmetric Calderbank Shor Steane (CSS) codes, where the two constituent classical parity check matrices are chosen with different error correction capability (e.g., Bose Chaudhuri Hocquenghem (BCH) codes for X errors and low density parity check (LDPC) codes for Z errors), are investigated in [17], [18]. Inherent to the CSS construction there are two distinct error correction capabilities for the X and the Z errors; the resulting asymmetric codes, denoted as $[[n, k, d_X/d_Z]]$, can correct up to $t_X = \lfloor (d_X - 1)/2 \rfloor$ Pauli X errors and $t_Z = \lfloor (d_Z - 1)/2 \rfloor$ Pauli Z errors per codeword. Due to the possibility of employing tools from classical error correction, many works have been focused on asymmetric codes based on the CSS construction, which, however, may not lead to the shortest codes (e.g., for the symmetric channel compare the $[[7, 1]]$ CSS code with the shortest $[[5, 1]]$ code [15], [16]).

In this paper we consider the Pauli-twirled asymmetric channel associated to the combination of amplitude damping and dephasing channels [18]. This model has $p_X = p_Y$ and $p_Z = A\rho/(A + 2)$, where ρ is the error probability, and the asymmetry is accounted for by the parameter $A = p_Z/p_X$. This parameter is a function of the relaxation time, T_1 , and the dephasing time, T_2 , which are in general different, leading to $A > 1$ [19], [27]. For this channel we study stabilizer codes able to correct a given number e_g of generic Pauli errors, plus a number e_z of Pauli errors of a specified type (e.g., Z errors). We denote these as asymmetric $[[n, k]]$ codes with correction capability (e_g, e_z) . Since we are targeting the shortest codes we do not constrain the design to CSS codes.

Specifically, we first derive a generalized version of the

Digital Object Identifier 10.1109/JSAIT.2020.XXXXXXX

quantum Hamming bound, which was originally developed for codes able to correct up to a number t of generic errors. The new generalized bound is valid also for codes with asymmetric error correction capability (e_g, e_Z) . Then, we construct, by a procedure based on syndrome assignment, a $[[9, 1]]$ code with $(e_g = 1, e_Z = 1)$ which, according to the new quantum Hamming bound, is the shortest possible code. We extend the construction method to the class of $[[n, 1]]$ codes with $e_g = 1$ and arbitrary e_Z , and provide as an example a $[[13, 1]]$ code with $(e_g = 1, e_Z = 2)$. Finally, we analytically compare the error correction capability of the new and of previously known codes, over asymmetric channels.

A. Notation

Throughout the paper we will use the following notation. A qubit is an element of the two-dimensional Hilbert space \mathcal{H}^2 , with basis $|0\rangle$ and $|1\rangle$ [12]. An n -tuple of qubits (n qubits) is an element of the 2^n -dimensional Hilbert space, \mathcal{H}^{2^n} , with basis composed by all possible tensor products $|i_1\rangle|i_2\rangle\cdots|i_n\rangle$, with $i_j \in \{0, 1\}$, $1 \leq j \leq n$. The Pauli operators, denoted as I, X, Z , and Y , are defined by $I|a\rangle = |a\rangle$, $X|a\rangle = |a \oplus 1\rangle$, $Z|a\rangle = (-1)^a|a\rangle$, and $Y|a\rangle = i(-1)^a|a \oplus 1\rangle$ for $a \in \{0, 1\}$. These operators either commute or anticommute. With $[[n, k]]$ we indicate a QECC that encodes k data qubits $|\varphi\rangle$ into a codeword of n qubits $|\psi\rangle$. We use the stabilizer formalism, where a stabilizer code \mathcal{C} is generated by $n - k$ independent and commuting operators $G_i \in \mathcal{G}_n$, called generators [12], [28], [29]. The code \mathcal{C} is the set of quantum states $|\psi\rangle$ satisfying $G_i|\psi\rangle = |\psi\rangle$, $i = 1, 2, \dots, n - k$. Assume a codeword $|\psi\rangle \in \mathcal{C}$ affected by a channel error described by the operator $E \in \mathcal{G}_n$. For error correction, the received state $E|\psi\rangle$ is measured according to the generators G_1, G_2, \dots, G_{n-k} , resulting in a quantum error syndrome $s(E) = (s_1, s_2, \dots, s_{n-k})$, with each $s_i = 0$ or 1 depending on the fact that E commutes or anticommutes with G_i , respectively. Note that the syndrome depends on E and not on the particular q-codeword $|\psi\rangle$. Moreover, measuring the syndrome does not change the quantum state, which remains $E|\psi\rangle$. Let $\mathcal{S} = \{s^{(1)}, s^{(2)}, \dots, s^{(m)}\}$ be the set of $m = 2^{n-k}$ possible syndromes, with $s^{(1)} = (0, 0, \dots, 0)$ denoting the syndrome of the operators E (including the identity I , i.e., the no-errors operator) such that $E|\psi\rangle$ is still a valid q-codeword. A generic Pauli error $E \in \mathcal{G}_n$ can be described by specifying the single Pauli errors on each qubit. We will use when necessary X_i, Y_i , and Z_i to denote the Pauli error X, Y , and Z , respectively, on the i -th qubit of a codeword.

II. HAMMING BOUNDS FOR QUANTUM ASYMMETRIC CODES

The standard quantum Hamming bound (QHB) gives a necessary condition for the existence of non-degenerate codes able to correct generic errors. It states that a QECC which encodes k qubits in n qubits can correct up to t generic errors per codeword only if [12], [30]

$$2^{n-k} \geq \sum_{j=0}^t \binom{n}{j} 3^j. \quad (1)$$

The bound is easily proved by noticing that the number of syndromes, 2^{n-k} , must be at least equal to that of the distinct errors we want to correct. Since for each position there could be three Pauli errors (X, Y or Z), the number of distinct patterns having j qubits in error is $\binom{n}{j} 3^j$, and this gives the bound (1).

In this paper we investigate non-degenerate QECCs which can correct some generic errors (X, Y or Z), plus some fixed Pauli type errors (e.g., Z errors). We derive therefore the following generalized quantum Hamming bound (GQHB).

Theorem 1 (Generalized Quantum Hamming Bound). *A quantum code which encodes k qubits in n qubits can correct up to e_g generic errors plus up to e_Z fixed Pauli type errors (e.g., Z errors) per codeword only if*

$$2^{n-k} \geq \sum_{j=0}^{e_g+e_Z} \binom{n}{j} \sum_{i=0}^{e_g} \binom{j}{i} 2^i. \quad (2)$$

Proof. For the proof we need to enumerate the different patterns of error. The number of patterns of up to e_g generic errors is given by (1) with $t = e_g$. Then, we have to add the number of configurations with $e_g < j \leq e_g + e_Z$ errors, composed by e_g generic Pauli errors and the remaining $j - e_g$ Pauli Z errors. We can write

$$2^{n-k} \geq \sum_{j=0}^{e_g} \binom{n}{j} 3^j + \sum_{j=e_g+1}^{e_g+e_Z} \binom{n}{j} [3^j - f(j; e_g)] \quad (3)$$

where $f(j; e_g)$ is a function that returns the number of non-correctable patterns of j errors. This is the solution of the following combinatorial problem: given j positions of the errors, count the number of all combinations with more than e_g symbols from the set $\mathcal{P}_{XY} = \{X, Y\}$ and the remaining from the set $\mathcal{P}_Z = \{Z\}$. We have therefore

$$f(j; e_g) = \sum_{i=0}^{j-e_g-1} \binom{j}{i} 2^{j-i} \quad (4)$$

which allows to write

$$\begin{aligned} g(j; e_g) &= 3^j - f(j; e_g) \\ &= \sum_{i=0}^j \binom{j}{i} 2^{j-i} - \sum_{i=0}^{j-e_g-1} \binom{j}{i} 2^{j-i} \\ &= \sum_{i=j-e_g}^j \binom{j}{i} 2^{j-i} = \sum_{i=0}^{e_g} \binom{j}{i} 2^i. \end{aligned} \quad (5)$$

It is easy to see that $g(j; e_g)$ is equal to 3^j if $j \leq e_g$, so substituting and incorporating the summation in (3) we finally obtain

$$2^{n-k} \geq \sum_{j=0}^{e_g+e_Z} \binom{n}{j} g(j; e_g) = \sum_{j=0}^{e_g+e_Z} \binom{n}{j} \sum_{i=0}^{e_g} \binom{j}{i} 2^i. \quad (6)$$

□

The GQHB in (2) can be used to compare codes which can correct t generic errors with codes correcting a total of t errors, with e_g of them generic and the others $t - e_g$ of a fixed type. In Table I we report the minimum code lengths

	$t = 1$	$t = 2$	$t = 3$	$t = 4$
$k = 1$	5,5	10,9	15,12	20,15
$k = 2$	7,7	12,10	16,14	21,17
$k = 3$	8,8	13,12	18,15	23,19

TABLE I: Comparison between the minimum code lengths $n_{\min}^{\text{QHB}}, n_{\min}^{\text{GQHB}}$ according to the Hamming bounds (1) and (2), respectively. For the GQHB the bounds refer to $t = e_g + e_Z$ with $e_g = 1$.

n_{\min} resulting from the Hamming bounds, for different values of the total number of errors t , and assuming $e_g = 1$ for the GQHB. From the table we can observe the possible gain in qubits for the asymmetric case.

III. CONSTRUCTION OF SHORT ASYMMETRIC CODES BY SYNDROME ASSIGNMENT

In this section we present a construction of short stabilizer asymmetric codes with $k = 1$ and $e_g = 1$, i.e., for $[[n, 1]]$ QECCs with error correction capability $(1, e_Z)$. The design is based on the error syndromes: specifically, we proceed by assigning different syndromes to the different correctable error patterns.

Let us first observe that the vector syndrome of a composed error $E = E_1 E_2$, with $E_1, E_2 \in \mathcal{G}_n$, can be expressed as $s(E) = s(E_1 E_2) = s(E_2 E_1) = s(E_1) \oplus s(E_2)$ where \oplus is the elementwise modulo 2 addition. Moreover, $XZ = iY$, and for the syndromes we have $s(X_i Z_i) = s(Y_i)$, $s(X_i Y_i) = s(Z_i)$, and $s(Y_i Z_i) = s(X_i)$. Hence, once we have assigned the syndromes for the single error patterns X_i and Z_i , with $i = 1, \dots, n$, the syndromes for all possible errors are automatically determined.

In the following, if not specified otherwise, the indexes i, j will run from 1 to n , and the index ℓ will run from 1 to $n - 1$. By definition the weight of a syndrome is the number of non-zero elements in the associated vector.

A. Construction of $[[n, 1]]$ QECCs with $e_g = 1, e_Z = 1$

For this case we need to assign $2n$ syndromes $s(X_i)$ and $s(Z_i)$ such that the syndromes of the errors $I, X_i, Y_i, Z_i, X_i Z_j, Y_i Z_j$, and $Z_i Z_j$, are all different $\forall i, j$ with $i \neq j$. We aim to construct the shortest possible code according to the GQHB, i.e., a code with $n = 9$ (see Table I). We start by assigning the syndromes of Z_i as reported in the Table II. In particular, we associate the all-one syndrome to a Z error on the last qubit, i.e., $s(Z_9) = (1, 1, \dots, 1)$. Therefore, $s(Z_9)$ has weight $n - k = 8$. With this choice we have assigned all possible syndromes of weight 1 and 8. Also, the combinations of $Z_i Z_j$ with $i \neq j$, cover all possible syndromes of weight 2 and 7.

To assign the syndromes of X_i we then use a Monte Carlo approach. To reduce the search space, i.e., the set of possible syndromes, we observe the following:

- The weight of $s(X_i)$ cannot be 3 or 6. This is because otherwise $s(Z_j X_i)$ would have weight 2 or 7 for some

	s_8	s_7	s_6	s_5	s_4	s_3	s_2	s_1
Z_1	0	0	0	0	0	0	0	1
Z_2	0	0	0	0	0	0	1	0
Z_3	0	0	0	0	0	1	0	0
Z_4	0	0	0	0	1	0	0	0
Z_5	0	0	0	1	0	0	0	0
Z_6	0	0	1	0	0	0	0	0
Z_7	0	1	0	0	0	0	0	0
Z_8	1	0	0	0	0	0	0	0
Z_9	1	1	1	1	1	1	1	1

TABLE II: Assigned syndromes for single Pauli Z errors.

	s_8	s_7	s_6	s_5	s_4	s_3	s_2	s_1
X_1	1	0	1	1	1	0	0	0
X_2	1	0	0	1	0	1	0	1
X_3	0	0	1	0	1	0	1	1
X_4	1	1	1	0	0	1	0	0
X_5	0	1	0	0	1	1	0	1
X_6	1	1	0	0	0	0	1	1

X_8	0	1	0	1	1	0	1	0
X_9	1	0	0	0	1	1	1	0

TABLE III: Syndromes for single Pauli X errors.

i and j , which are already assigned for errors of the type $Z_i Z_j$. Therefore the possible weights for $s(X_i)$ are only 4 and 5. The same observation applies to $s(Y_i)$. We then fix the weight for $s(X_i)$ equal to 4.

- We can obtain $s(Y_\ell)$ with weight 5 for $\ell = 1, \dots, 8$, by imposing to “0” the ℓ -th element of the syndrome of X_ℓ . Note that Y_9 has weight 4 since X_9 has weight 4.

By following the previous rules, a possible assignment obtained by Monte Carlo is reported in Table III.

From Table III and Table II we can then build the stabilizer matrix with the following procedure, where $s_j(X_i)$ indicates the j -th elements of the X_i ’s syndrome:

- if $s_j(X_i) = 0$ and $s_j(Z_i) = 0$ put the element I in position (j, i) of the stabilizer matrix because it is the only Pauli operator which commutes with both.
- if $s_j(X_i) = 1$ and $s_j(Z_i) = 0$ put the element Z in position (j, i) of the stabilizer matrix because it is the only Pauli operator which commutes with Z and anti-commute with X .
- if $s_j(X_i) = 0$ and $s_j(Z_i) = 1$ put the element X in position (j, i) of the stabilizer matrix because it is the only Pauli operator which commutes with X and anti-commute with Z .
- if $s_j(X_i) = 1$ and $s_j(Z_i) = 1$ put the element Y in position (j, i) of the stabilizer matrix because it is the only Pauli operator which anti-commutes with both.

The resulting stabilizer matrix, after checking the commutation conditions, is represented in Table IV. According to the GQHB the code specified in the table is therefore the shortest possible code for $k = 1, e_g = 1$ and $e_Z = 1$.

TABLE IV: Stabilizer for a $[[9, 1]]$ QECC with $e_g = 1$ and $e_z = 1$.

B. Construction of $[[n, 1]]$ QECCs with $e_g = 1$ and $e_z \geq 1$

The construction presented in the previous section can be generalized to the case of more fixed errors, $e_z \geq 1$. In this section we indicate $\tilde{t} = e_g + e_z$. We start by adopting the same assignment proposed in Table II for a single Z error, i.e., $s(Z_\ell)$ has a 1 in position ℓ , $\ell \neq n$, and $s(Z_n) = (1, 1, \dots, 1)$. Note that $s(Z_n)$ has weight $n - k = n - 1$. In this way, it is easy to see that we use all possible syndromes with weight in the range $[0, \tilde{t}]$ and $[n - \tilde{t}, n - 1]$, covering all possible error operators with up to \tilde{t} errors of type Z . For the assignment of the syndromes $s(X_i)$ we can generalize the previously exposed arguments, as follows:

- The weight of $s(X_i)$ cannot be less than $2\tilde{t}$ or greater than $n - 2\tilde{t}$. This is because otherwise $s(Z_{j_1} \dots Z_{j_L} X_i)$ would have weight in the range $[0, \tilde{t}]$ or $[n - \tilde{t}, n - 1]$ for some $L \leq e_z$ and some choices of j_1, \dots, j_L . These syndromes are already assigned for errors of the type $Z_{j_1} \dots Z_{j_M}$ for some $M \leq e_z$ and some choices of j_1, \dots, j_M . Therefore the possible weights for $s(X_i)$ are in the range $[2\tilde{t}, n - 2\tilde{t}]$. The same observation applies to $s(Y_i)$.
- Setting the ℓ -th element of the syndrome of X_ℓ to "0" we obtain that $s(Y_\ell)$ has the weight of $s(X_\ell)$ increased by 1, with $\ell = 1, \dots, n - 1$. Hence, in order to have both $s(X_\ell)$ and $s(Y_\ell)$ in the permitted range, we must have $n - 4\tilde{t} \geq 1$. Note that this constraint can be stricter than the GQHB. For example, we cannot construct the $[[12, 1]]$ code with $e_g = 1, e_z = 2$. The comparison between the GQHB and the construction bound $n - 4\tilde{t} \geq 1$ is reported in Table VI.
- About X_n and Y_n , we recall that $s(Z_n) = s(X_n) \oplus s(Y_n)$ and that we choose $s(Z_n) = (1, 1, \dots, 1)$. Therefore, in the positions where the syndrome of X_n has a 1, the syndrome of Y_n has a 0, and viceversa. As a consequence, the sum of the weights of $s(X_n)$ and $s(Y_n)$ is $n - 1$. Then, a good choice is to assign to $s(X_n)$ a weight $\lceil (n - 1)/2 \rceil$ or $\lfloor (n - 1)/2 \rfloor$. In this case, if n is odd $s(Y_n)$ would have the same weight, which is in the correct range because $n - 4\tilde{t} \geq 0$ is guaranteed by the previous point; if n is even the weights are still in the correct range because $n - 4\tilde{t} \geq 1$.

The procedure is summarized as Algorithm 1. For example, we obtained the $[[13, 1]]$ QECC with $e_g = 1$ and $e_z = 2$ reported in Table VII.

\tilde{t}	1	2	3	4	5	6

TABLE V: Comparison between the minimum code lengths according to the generalized quantum Hamming bound (2) and the construction bound $n \geq 1 + 4\tilde{t}$. The bounds refer to $\tilde{t} = e_g + e_z$ with $e_g = 1$.

Algorithm 1: Construction by syndrome assignment, $k = 1, e_g = 1$.

Result: Stabilizer matrix.

```

Choose  $n$  and  $\tilde{t}$  to satisfy the constraint  $n - 4\tilde{t} \geq 1$ ;
Assign  $s(Z_i)$  as in Table II;
Pick a random syndrome for  $s(X_n)$  with weight
 $\lfloor (n - 1)/2 \rfloor$ ;
Assign  $s(Y_n)$ ,  $s(X_n Z_{j_1} \dots Z_{j_L})$  and
 $s(Y_n Z_{j_1} \dots Z_{j_L})$  for each  $L = 1, \dots, e_z$  and for
each possible combination of  $j_1, \dots, j_L \neq n$ ;
for  $\ell = 1$  to  $n - 1$  do
    goodPick = 0;
    while goodPick == 0 do
        Pick a random syndrome for  $s(X_\ell)$  with
        weight in  $[2\tilde{t}, n - 2\tilde{t} - 1]$  and  $s_\ell(X_\ell) = 0$ ;
        if  $s(Y_\ell)$ ,  $s(X_\ell Z_{j_1} \dots Z_{j_L})$  and
         $s(Y_\ell Z_{j_1} \dots Z_{j_L})$  are not already assigned
        for all possible combinations then
            goodPick = 1;
            Assign  $s(Y_\ell)$  and all  $s(X_\ell Z_{j_1} \dots Z_{j_L})$ ,
             $s(Y_\ell Z_{j_1} \dots Z_{j_L})$ ;
        if no more possible syndromes then
            Restart the algorithm;
Construct the stabilizer matrix from  $s(X_i)$  and  $s(Z_i)$ ;
Check if all of the generators commute with each
other.
```

The proposed method to design asymmetric codes is based on a Monte Carlo search over a reduced syndrome assignments space. To give an idea of the time needed to find a valid code, we performed several runs of the algorithm. In our simulations the number of expected trials for the asymmetric $[[9, 1]]$ case is around 20, and for the asymmetric $[[13, 1]]$ case is around 1100.

IV. PERFORMANCE ANALYSIS OVER ASYMMETRIC CHANNELS

It is well known that the Codeword Error Probability (CWEP) for a standard $[[n, k]]$ QECC which corrects up to t generic errors per codeword is

$$P_e = 1 - \sum_{j=0}^t \binom{n}{j} (1 - \rho)^{n-j} \rho^j \quad (7)$$

where $\rho = p_X + p_Y + p_Z$ is the qubit error probability.

 TABLE VI: Stabilizer for a $[[13, 1]]$ QECC with $e_g = 1$ and $e_Z = 2$.

We now generalize this expression to an $[[n, k]]$ QECC which corrects up to e_g generic errors and up to e_Z Pauli Z errors per codeword, over a generic asymmetric channel with Pauli error probabilities p_X, p_Y and p_Z . To this aim, we first note that the patterns of correctable errors are those discussed in Section III. Then, by weighting each pattern with the corresponding probability of occurrence, it is not difficult to show that the performance in terms of CWEP is

$$P_e = 1 - \sum_{j=0}^{e_g+e_Z} \binom{n}{j} (1-\rho)^{n-j} \xi(j; e_g) \quad (8)$$

where

$$\xi(j; e_g) = \begin{cases} \rho^j & \text{if } j \leq e_g \\ \sum_{i=j-e_g}^j \binom{j}{i} p_Z^i \sum_{\ell=0}^{j-i} \binom{j-i}{\ell} p_X^\ell p_Y^{j-i-\ell} & \text{otherwise.} \end{cases} \quad (9)$$

In the case of asymmetric channels with $p_X = p_Y = \rho/(A+2)$, $p_Z = A\rho/(A+2)$, and $A = p_Z/p_X$, the expression in (8) can be simplified to

$$P_e = 1 - \sum_{j=0}^{e_g+e_Z} \binom{n}{j} (1-\rho)^{n-j} \rho^j \times \left(1 - 2^{j+1} \frac{(A/2)^{j-e_g} - 1}{(A-2)(A+2)^j} u_{j-e_g-1} \right) \quad (10)$$

where $u_i = 1$ if $i \geq 0$, otherwise $u_i = 0$.

Using the previous expressions, we report in Fig. 1 the performance in terms of CWEP for different codes, assuming an asymmetric channel. The parameter A accounts for the asymmetry of the channel, and for $A = 1$ we have the standard depolarizing channel. In the figure we plot the CWEP for the new asymmetric $[[9, 1]]$ code specified in Table IV with $e_g = 1$ and $e_Z = 1$, reported in the plot as \mathcal{C}_A , over channels with asymmetry parameter $A = 1, 3$ and 10 . For comparison, in the same figure we report the CWEP for the known 5-qubits code, the Shor's 9-qubits code (indicated in the figure as \mathcal{C}_S), both correcting $t = 1$ generic errors, and a $[[11, 1]]$ code with $t = 2$ [31]. Additionally, for a fair comparison, we analyzed the Shor's code when used in an extended mode for patterns of two errors. In fact, besides arbitrary single errors, the Shor's

code can also correct some combinations of multiple errors. The most relevant multiple errors for our asymmetric channel are in the form $Z_i Z_j$, $X_i Z_j$, and $Y_i Z_j$. In this regard, it can be verified that the Shor code can be used to correct 9 out of the 36 possible $Z_i Z_j$ errors, all 72 possible $X_i Z_j$ errors, and 18 out of the 72 possible $Y_i Z_j$ errors. The Shor's code used with this extended error correction capability is reported in the following as \mathcal{C}_{SE} .

About the results in Fig. 1, we remark that for symmetric codes the performance does not depend on the asymmetry parameter A , but just on the overall error probability ρ . For these codes, for a given t the best CWEP is obtained with the shortest code. As expected, the performance of the new asymmetric $[[9, 1]]$ code improves as A increases. In particular, for the symmetric channel, $A = 1$, the 5-qubits code performs better than the new one, due to its shorter codeword size. However, already with a small channel asymmetry, $A = 3$, the new code performs better than the 5-qubits code in the range of interest. For $A = 10$ the new code performs similarly to the $[[11, 1]]$ symmetric code with $t = 2$. Asymptotically for large A , the channel errors tend to be of type Z only, and consequently the new code behaves like a code with $t = 2$. In the case of Shor code with extended error correction capability, it can be observed that when varying A the curves are quite close each others. This is due that for the asymmetric channel the most important error patterns are the $Z_i Z_j$, and this code can correct only a subset of all possible patterns of this type. For the same reason the curve for $A = 10$ is worse than that for $A = 3$.

We next move to the case $e_g = 1, e_Z = 2$, and compare our asymmetric $[[13, 1]]$ code of Table VI with two symmetric codes, and with the $[[15, 1, 3/7]]$ CSS asymmetric code [18]. The performance of our asymmetric and of symmetric codes is given in general by (8). For the CSS code, we observe that it corrects all patterns with up to $e_g = 1, e_Z = 2$ errors, plus patterns with one X and three Z errors. Therefore, the CWEP for the $[[15, 1, 3/7]]$ CSS code is

$$P_e = 1 - 15 \binom{14}{3} p_X p_Z^3 (1-\rho)^{11} - \sum_{j=0}^3 \binom{15}{j} (1-\rho)^{15-j} \xi(j; 1) \quad (11)$$

Fig. 1: Performance of short codes over an asymmetric channel, $k = 1$. Code $[[5, 1]]$: 5-qubits code with $t = 1$. Code $[[11, 1]]$: 11-qubits code with $t = 2$. C_S $[[9, 1]]$: 9-qubits code from [15] used with $t = 1$. C_{SE} $[[9, 1]]$: 9-qubits code from [15] used also for the correctable two-errors patterns with at least one Z . C_A $[[9, 1]]$: 9-qubits asymmetric code with $e_g = 1, e_Z = 1$.

where $\xi(\cdot; \cdot)$ is given by (9). The analytical performance of the different QECCs, as given by (8) and (11), is reported in Fig. 2. We can see here that the proposed $[[13, 1]]$ asymmetric code performs better than the CSS, and provides a performance similar to the longer symmetric $[[17, 1]]$ code for large A .

V. CONCLUSIONS

We have investigated a new class of stabilizer codes for quantum asymmetric Pauli channels, capable to correct up to e_g generic errors, plus e_Z errors of type Z . For these codes we generalized the quantum Hamming bound, and derived the analytical expression of the performance over asymmetric channels. We designed a $[[9, 1]]$ QECC which is the shortest, according to the new bound, capable to correct up to one generic error plus one Z error, and a $[[13, 1]]$ QECC capable to correct up to one generic error plus two Z errors. The comparison with known symmetric QECCs confirms the advantage of the proposed codes in the presence of channel asymmetry.

Marco Chiani (M’94-SM’02-F’11) received the Dr. Ing. degree (*summa cum laude*) in electronic engineering and the Ph.D. degree in electronic and computer engineering from the University of Bologna, Italy, in 1989 and 1993, respectively.

He is a Full Professor of Telecommunications at the University of Bologna. During Summer 2001, he was a Visiting Scientist at AT&T Research Laboratories, Middletown, NJ. Since 2003 he has been a frequent visitor at the Massachusetts Institute of Technology (MIT), Cambridge, where he presently

holds a Research Affiliate appointment. His research interests are in the areas of communications theory, wireless systems, coding theory, and statistical signal processing. In 2012 he has been appointed Distinguished Visiting Fellow of the Royal Academy of Engineering, UK. He served as elected Chair (2002–2004) of the Radio Communications Committee of the IEEE Communication Society and as Editor (2000–2007) of *Wireless Communication for the IEEE TRANSACTIONS ON COMMUNICATIONS*.

He received the 2011 IEEE Communications Society Leonard G. Abraham Prize in the Field of Communications Systems, the 2012 IEEE Communications Society Fred W. Ellersick Prize, and the 2012 IEEE Communications Society Stephen O. Rice Prize in the Field of Communications Theory.

Lorenzo Valentini received the M.S. degree (*summa cum laude*) in Electronics and Telecommunications Engineering from the University of Bologna, Italy, in 2019. After graduation he has been with the Interdepartmental Centre for Industrial ICT Research of the University of Bologna, working on Internet of Things for the project CoAch. He is currently a Ph.D. student in Electronics, Telecommunications and Information Technologies Engineering at the University of Bologna. His research interests include communication theory, wireless sensor networks and

quantum information theory.
