Abstract

While there has been plenty of research around family firm governance and management, less is known about the way in which family firm image is perceived by consumers. This research aims at filling the gap by investigating the chained links between family firm status and image, and the key brand elements identified by extant literature. The hypotheses are tested through an application to the wine industry with a sample of over 1,500 wine drinkers residing in Australia, Italy, and the United States. The results reveal several linkages between the distinctive family nature of a business and the loyalty of consumers. All brand knowledge constructs are positively affected by family firm image, and influence brand trust and satisfaction. Individual path coefficients highlight differences between countries. Evidence regarding the cultural interdependencies provides guidance for policy makers. Practitioners can consider this research when defining the relationship with consumers of family firms.

Keywords: family firm image; family business; brand equity; consumer behaviour; structural equation modelling; wine

43 **1 Introduction**

44 Family firms play a central role in the world economy and are a main driver of job
45 creation, even in highly industrialised nations (Astrachan & Shanker, 2003; Klein, 2000).
46 Moreover, the literature seems to attribute several positive aspects to this type of firm
47 (Arregle, Hitt, Sirmon, & Very, 2007). These favourable aspects are often explained by the
48 strong link between ownership and control in a business, which reduces the presence of
49 agency problems (Aronoff & Ward, 1995). However, like other firms that are embedded in an
50 ever-globalising environment, family firms face increasing competition from various players
51 in the marketplace. For example, given that most family firms are small and medium
52 companies, these businesses may be at a relative disadvantage with respect to their access to
53 capital (Gallucci, Santulli, & Calabrò, 2015) and hence face more severe financial constraints
54 than non-family companies and publicly-traded companies. Family firms not only differ from
55 their non-family competitors (Gedajlovic, Carney, Chrisman, & Kellermanns, 2012) but also
56 are a highly heterogeneous category of businesses themselves (Daspit, Chrisman, Sharma,
57 Pearson, & Mahto, 2018). This heterogeneity is reflected by the fact that some businesses opt
58 to openly communicate their family identity, while other businesses do not communicate such
59 family references publicly.

60 In the same way that studies have pointed out favourable behavioural traits of family
61 firms towards their stakeholders, consumers may perceive these differences and hold
62 favourable associations regarding this type of firm. This fact raises the question of whether a
63 common image of the family firms exists in consumers' minds. Keller (1993) argues that
64 whenever stakeholders are aware of a brand and hold positive associations regarding this
65 brand, brand equity is created. It is further suggested that brands can be characterised as
66 specific sets of associations that are distinctive from one another and hence serve as a means

67 of differentiation in the marketplace. Blombäck (2011) provides the theoretic foundation for
68 how such distinctive characteristics may derive from the family nature of a business. Indeed,
69 according to Binz, Hair, Pieper and Baldauf (2013), consumers attribute some relational and
70 business qualities to family firms that set them apart from their non-family counterparts.
71 Therefore, family firm image may be linked to meaningful associations that influence
72 consumer behaviour, and a family firm's status and its active communication can be a
73 strategic resource in the marketplace for this type of businesses (Blombäck, 2009; Esch,
74 Langner, Schmitt, & Geus, 2006).

75 While the internal characteristics of family firms, such as the governance of the
76 business and further organisational features, are well known, particular research gaps exist in
77 relation to family firm image. Beck (2016) has shown in a recent structured review
78 concerning brand management of family firms that much past research has focused on
79 conceptual papers and business-related studies. However, consumer studies have been scarce
80 in the past. Despite pioneering theoretical contributions (i.e. Blombäck, 2009, 2010, 2011),
81 much evidence in the past has been anecdotal (Blombäck & Botero, 2013; Orth & Green,
82 2009). Scholars have only recently begun to focus more attention on investigating consumer
83 perceptions of family firms and the related issues of branding (Astrachan Binz, Botero,
84 Astrachan, & Prügl, 2018). To date, only a few applied studies exist in the field. Most
85 recently, Lude and Prügl (2018) have highlighted the preference of consumers for family firm
86 brands in experimental consumer studies. However, little knowledge of the factors that
87 constitute this consumer preference for family firms exists (Sageder, Mitter, & Feldbauer-
88 Durstmüller, 2018). More importantly, no validated framework that provides a single
89 structural approach to modelling the effect of family firm status on behavioural outcomes has
90 been developed by scholarly research (Felden, Fischer, Graffius, & Marwede, 2016). In
91 addition, it is also unknown how influencing factors may exhibit heterogeneity with respect to

92 the cultural background of different countries. Babin et al. (2017) state that furthering the
93 knowledge related to the identity and the branding of family firms and its related
94 communication to stakeholders is highly relevant for future research.

95 In light of the points presented above, this research investigated the chained links
96 between the informational cue 'family firm status' and brand associations, which have been
97 identified as relevant drivers of consumer behaviour. Although some of these links have
98 already been established by prior studies, a comprehensive theory-grounded model is
99 proposed and validated for the first time in this paper.

100 A structural framework of how family firm identity affects behavioural outcomes was
101 applied to consumers, since they represent a key stakeholder group for many small and
102 medium companies. The structural framework of this study was derived from previously
103 validated frameworks in the fields of marketing (Chaudhuri & Holbrook, 2001), brand (Esch
104 et al., 2006) and family firm research (Sageder et al., 2018). The application of this
105 framework was performed on the wine category since it represents a highly branded product
106 category with considerable presence of both family and corporate wineries. The sample
107 included consumers residing in three different countries, Australia, Italy and the United States
108 (US), to extend the generalisability of the findings.

109 This research addresses significant knowledge gaps since, to date, little consumer-
110 focused research exists in the field of family business research. The findings will not only fill
111 academic gaps but also address recent requests for brand management research by
112 practitioners in the family business context, such as family business consultants and managers
113 (Beck, 2016). Finally, the results will also help businesses understand the behavioural effects
114 that key brand elements evoke in consumers and generate an understanding of the chain of
115 effects on how family firms develop customer-based brand equity.

2 Literature Review

This study provides insight into the question of how customer-based brand equity occurs in family firms. It synthesises previously validated frameworks by Chaudhuri and Holbrook (2001) and Esch et al. (2006), who established the effect of brand image and brand knowledge on behavioural outcomes in consumers. A meta-analysis of Sageder et al. (2018) further identifies relevant constructs of consumer-based brand image in family firms. Many of these constructs overlap with notable characteristics of price premia in the premium food sector (Anselmsson, Bondesson, & Johansson, 2014). The aforementioned contributions serve as the foundation of the present study.

This study's framework is founded on the concepts of value and branding. Particular emphasis is placed on specific links to hedonic products. Premium wine is the chosen product category of application because it is associated with hedonic characteristics.

2.1 Value of Products

Theory about the value of products is linked to literature on branding. Keller (1993) points out the three benefits from which brands and products derive their value: functional, experiential and symbolic benefits. For hedonic products, such as wine, experiential and symbolic benefits are of particular value (Charters & Pettigrew, 2005). The underlying process of product valuation is characterised by high complexity and also needs to be considered from a sociological angle. Another phenomenon linked to the valuation of products is asymmetric information. In many situations, agents are not able to assess the intrinsic quality of a product at the time of purchase. Hence, brands play a specific signalling role for intrinsic product characteristics. In situations of high uncertainty, brands can reduce the cost of information through their signalling function and generate additional value for agents (Erdem, Swait, & Valenzuela, 2006). While this aspect relates mainly to functional and experiential benefits, Beckert, Rössel and Schenk (2017) argue that the economic valuation of

141 products is based not only on the aforementioned objectively measurable intrinsic qualities,
142 but also on symbolic benefits. Symbolic characteristics stem from a complex sociological
143 process that takes place in the field of cultural production (Bourdieu, 1996). It is argued that
144 particular symbolic criteria, such as artisanship, tradition and individualism, have been
145 gaining more importance for consumers (Maguire, 2018). In particular, products that emanate
146 from a production process that can hardly be standardised require an understanding of these
147 factors, as in the case of luxury wines (Beverland, 2005).

148 **2.2 The Family Nature of Firms and Brands**

149 Many definitions of the family firm exist in the literature. When synthesising the
150 consensus of this existing body of literature, the following definition is formed: A family firm
151 is a business that is owned and operated by members of a family (related by blood or
152 marriage) and in which decision-making is influenced by one or more family generations
153 (Westhead & Cowling, 1998). This definition underscores the unique pooling of ownership
154 and control, which is the central revolving motive in these firms and a major source of their
155 distinctive organisational identity (Sharma, 2008). It can further be constituted that this hybrid
156 identity of family firms results in a higher concern about their reputation in the public
157 compared with their non-family counterparts (Dyer & Whetten, 2006). This is also owed to
158 family firms' focus on normative values (Bingham, Dyer, Smith, & Adams, 2011). One
159 example is the fiduciary responsibility towards long-lived assets, which originates in the
160 trans-generational vision of these companies. This ability to plan across long periods of time
161 ahead is often an element in non-family businesses, where leaders must carefully consider
162 their performance in the short term. The above sentences exemplify that family firms exhibit a
163 differential behaviour in the marketplace through idiosyncratic interaction of family and
164 business subsystems. This can be perceived by consumers and ultimately influences their
165 behavioural outcomes through different relationships with these companies. Nonetheless,

166 heterogeneity may not only exist between family and corporate firms but also within the
167 group of family firms. For this reason, Beck and Kenning (2015) highlight the importance of
168 considering the degree to which a business is perceived to be a family firm from a consumer
169 perspective (family firm status). The above-mentioned points lead to the fundamental first
170 hypothesis of this study, which tests whether consumers distinctively perceive actual family
171 firms as such:

172 – Family firm status positively affects family firm image (Hypothesis 1).

173 Differences exist between family and non-family firms from a business point of view.
174 However, also from a consumer point of view perceptual differences are associated between
175 these groups. The characteristic of family firms is drawn from human associative memory
176 theory: The word family is linked to a multitude of meaningful experiences throughout human
177 life and represents a concept of high relevance for humans (Beck & Kenning, 2015). In the
178 human mind, many and meaningful associations are triggered when external stimuli of the
179 family concept are present. This is an important aspect since not all associations with brands
180 are of equal importance for humans (French & Smith, 2013). The powerful advantage of the
181 family attribute resides in the fact that associated elements are a mix of everyday experiences,
182 which at the same time reflect meanings central to an individual's life. Fournier (1998) argues
183 that such 'lived experiences' enable brand attributes (in the context of this paper, the family
184 attribute) to transcend category-specific themes and generate a strong consumer-relevant
185 purpose of a brand that parallels a person's individual life (p. 367). This is in line with Esch
186 (2008), who makes the point that strong brands evoke associations that are linked to intense
187 emotions and images. The following section explains relevant elements of customer-based
188 brand equity in family firms.

189 **2.3 Customer-based Brand Equity**

190 Customer-based brand equity is defined as the ‘differential effect of brand knowledge
191 on customer response to the marketing of the brand’ (Keller, 1993, p. 2). According to the
192 model proposed by Esch et al. (2006), the customer response originates in brand knowledge
193 and is mediated by brand relationship. While the relationship between brand relationship and
194 behavioural outcomes is well developed in the literature (Chaudhuri & Holbrook, 2001), less
195 knowledge exists on its antecedents. The conceptual work of Esch et al. (2006) provided the
196 foundation to investigate further how customer-based brand equity is derived from brand
197 knowledge.

198 Brand knowledge is constituted from brand awareness and brand image (Esch et al.,
199 2006; Keller, 1993), with brand awareness being a necessary precondition to brand image.
200 Brand image is defined as the ‘perceptions about a brand as reflected by the brand
201 associations held in consumer memory’ (Keller, 1993, p. 13) and hence is a multifaceted
202 construct that represents the actual influencing element of brand relationship. In the literature
203 it is assumed that family firms are ‘a special type of company with typical associations’
204 (Sageder et al., 2018, p. 348). Since this study investigated wine, specific consideration was
205 given to prior research in the food and drink category (Anselmsson et al., 2014). The
206 following seven key attributes that influence brand relationship have been identified as core
207 distinctive elements in family firms (Sageder et al., 2018): uniqueness, social image,
208 perceived quality, localness, corporate social responsibility, long-term orientation and
209 customer orientation.

210 Perceived customer orientation is an important element of a firm’s perceived image
211 (Walsh & Beatty, 2007). The beneficial effects of customer orientation on trust and
212 satisfaction is well outlined in a body of literature (Swanson, Kelley, & Dorsch, 1998; Walsh
213 & Beatty, 2007). Family firms are considered to show strong relational qualities, such as

214 customer orientation (Craig, Dibrell, & Davis, 2008; Tokarczyk, Hansen, Green, & Down,
215 2007), which creates a competitive advantage for these firms in the marketplace. Finally, the
216 study tested the following hypotheses:

- 217 – Family firm image positively affects customer orientation (Hypothesis 2).
- 218 – Customer orientation positively affects brand trust (Hypothesis 3) and brand
219 satisfaction (Hypothesis 4).

220 The willingness of a brand to prioritise decisions, even if returns only come into effect
221 after an extended period (long-term orientation), creates trust (Lohtia, Bello, & Porter, 2009)
222 and satisfaction (Griffith, Harvey, & Lusch, 2006). Owing to the particular unity of ownership
223 and control, family businesses are more likely to implement long-term strategies compared
224 with their non-family counterparts (Heine, Phan, & Atwal, 2016; Le Breton-Miller & Miller,
225 2015). This study assumed that:

- 226 – Family firm image positively affects consumers' perceptions of businesses long-term
227 orientation (Hypothesis 5).
- 228 – Long-term orientation positively affects brand trust (Hypothesis 6) and brand
229 satisfaction (Hypothesis 7).

230 Corporate social responsibility (CSR), which is defined as a set of policies and actions
231 considering an equilibrium of economic, social and environmental goals, has the propensity to
232 influence the relationship between a brand and its consumers (Aguinis & Glavas, 2012). Prior
233 studies have found significant links between CSR and consumer trust (Vlachos, Tsamakos,
234 Vrechopoulos, & Avramidis, 2009) and satisfaction (Luo & Bhattacharya, 2006). CSR is a
235 central attribute that is strongly linked to family firms (Blodgett, Dumas, & Zanzi, 2011). The
236 study tested the following hypotheses:

- 237 – Family firm image positively affects CSR perceptions (Hypothesis 8).

238 – CSR positively affects brand trust (Hypothesis 9) and brand satisfaction (Hypothesis
239 10).

240 Localness is defined as the degree to which a brand symbolises local values and needs.
241 Brands can differentiate themselves through their localness and build a loyal customer base
242 (M. Beverland & Luxton, 2005). In the case of food and wine, local provenance and
243 association with the territory are a point of particular importance (M. Beverland, 2006;
244 Özsomer, 2012). Such local origin of food is thought to increase consumer trust (Schuiling &
245 Kapferer, 2004) and satisfaction (Bratanova et al., 2015). Family firms are believed to take a
246 leading role in the preservation of local traditions and products (Fonte, 2008). Hence, this
247 study hypothesised that:

248 – Family firms exhibit localness to a higher degree than do their non-family counterparts
249 (Hypothesis 11).

250 – Localness can be seen as a positively linked antecedent of brand trust (Hypothesis 12)
251 and brand satisfaction (Hypothesis 13).

252 Perceived quality is a central element of customer-based brand equity (Aaker, 1996;
253 Keller, 1993) because it creates a fundamental functional benefit of the brand. Thus,
254 perceived quality is strongly linked with brand satisfaction (Fornell, Johnson, Anderson, Cha,
255 & Bryant, 1996) and brand trust (Aydin & Özer, 2005). The link between the family nature of
256 a firm and product quality has been pointed out by Blodgett et al. (2011). This link is
257 particularly the case in situations of uncertainty about the intrinsic quality of products (Beck
258 & Kenning, 2015). Hence, the structural model assumes that:

259 – A positive relationship exists between family firm image and perceived quality
260 (Hypothesis 14).

261 – A positive relationship exists between perceived quality and brand trust (Hypothesis
262 15) as well as brand satisfaction (Hypothesis 16).

263 The role of brands and their signalling effect of social status is implied in earlier
264 studies and explicitly described as an essential part of symbolic brand benefits (Keller, 1993).
265 The concept of social status has been shown to be linked to trust and satisfaction in a
266 consumer context (Jin, Line, & Merkebu, 2016; Walsh, Shiu, & Hassan, 2014). It is
267 commonly argued that products of family firms, particularly in the luxury goods sector, are
268 often linked to high social prestige (Bresciani, Bertoldi, Giachino, & Ferraris, 2015). The
269 above-referenced literature leads to a further assumption that:

- 270 – Family firm image positively affects the social image of a brand (Hypothesis 17).
- 271 – Social image is positively linked to brand trust (Hypothesis 18) and brand satisfaction
272 (Hypothesis 19).

273 Uniqueness describes the degree to which a brand is perceived to be different from its
274 competitors, and it is an intrinsic element in Keller's (1993) definition of customer-based
275 brand equity. Uniqueness has been found to be a relevant antecedent of brand trust and
276 satisfaction (He, Li, & Harris, 2012; Tian, Bearden, & Hunter, 2001). Sageder, Mitter and
277 Feldbauer-Durstmüller (2018) advocate that through their close ties with stakeholders, family
278 firms develop a unique firm image, which implies a positive correlation between the family
279 attribute and uniqueness. The above discussion leads to the following hypotheses:

- 280 – Family firm image positively affects uniqueness (Hypothesis 20).
- 281 – Uniqueness positively affects brand trust (Hypothesis 21) and brand satisfaction
282 (Hypothesis 22).

283 The links between behavioural outcomes and brand relationship are well understood.
284 Behavioural outcomes are the phenomenological expression of customer-based equity.
285 Following earlier studies, such as Chaudhuri and Holbrook (2001), behavioural outcomes are
286 conceptualised as loyalty. Further differentiation is made between attitudinal and behavioural
287 loyalty. Such a dual perspective of loyalty has been widely adopted in research (DeWitt,

288 Nguyen, & Marshall, 2008; Ganesh, Arnold, & Reynolds, 2000; Jones & Taylor, 2007;
289 Kamran-Disfani, Mantrala, Izquierdo-Yusta, & Martinez-Ruiz, 2017; Taylor, Celuch, &
290 Goodwin, 2004). Two key components of brand relationship have emerged in the literature
291 and have been validated earlier (Esch et al., 2006): brand trust and brand satisfaction.
292 Interdependencies between behavioural outcomes and brand relationship exist. Brand
293 relationship can be seen as the bonding element between brand knowledge and behavioural
294 outcomes. Therefore, based on the above-mentioned earlier research findings, the present
295 study assumed the following hypotheses:

- 296 – Brand trust positively affects attitudinal loyalty (Hypothesis 23) as well as behavioural
297 loyalty (Hypothesis 24).
- 298 – Positive links exist between brand satisfaction and attitudinal loyalty (Hypothesis 25)
299 as well as behavioural loyalty (Hypothesis 26).

300 Figure 1 shows the hypothesised structural model, which is based on the individual
301 relationships between the variables identified by prior research.

302 --- Figure 1 here ---

303 **3 Method**

304 **3.1 Data Collection**

305 To test the research hypotheses, a survey was carried out in Australia, Italy and the US
306 in October 2017. Two key wine producing countries in the New (Australia) and the Old
307 (Italy) World of wine were selected, as well as their most important intersecting import
308 country (the US). To qualify for participation in the survey, respondents were selected on the
309 basis that they drank wine at least once a month (regular wine drinker). In addition,
310 respondents had to have bought wine from family and non-family wineries within the past
311 year, since participants were asked to provide their perceptions and experiences of both firm
312 types. Representativeness of a panel of respondents, provided by a leading global panel

313 provider, was ensured through quota sampling. The sample was representative of regular wine
314 drinkers in terms of gender, age and geographic regions for each country. The survey
315 questions were developed in English and then translated to the local language, if necessary.
316 Translation bias was addressed through back translation to English (Craig & Douglas, 2005).
317 Logic control questions were implemented in the survey to ensure data validity. Structural
318 response bias of the survey was addressed through randomisation of the response items for
319 each question, randomisation of questions at the block level of the survey and randomisation
320 of blocks within the logic requirements of the survey. After screening for incomplete or
321 invalid responses, 513 Australian, 518 Italian and 510 US respondents remained in the
322 sample. The characteristics of the sample with respect to demographic variables can be found
323 in Table 1.

324 --- Table 1 here ---

325 **3.2 Measures**

326 The survey instrument was developed based on previously validated scales from
327 earlier research, and items were presented on 7-point Likert scales. Attitudinal and
328 behavioural loyalty were measured through the scales proposed by Chaudhuri and Holbrook
329 (2001). Trust was measured on a scale presented by the same authors. Fornell et al. (1996)
330 developed the scale of satisfaction used in this study. Uniqueness and perceived quality were
331 measured on a scale developed by Netemeyer et al. (2004), social image on a scale by
332 Sweeney and Soutar (2001), localness on a scale by Steenkamp, Batra and Alden (2003), CSR
333 on a scale by Wagner, Lutz and Weitz (2009), long-term orientation on a scale of Lohtia et al.
334 (2009) and customer orientation on a scale of Bartikowski, Walsh and Beatty (2011). The
335 measurement of family firm image developed by Beck and Kenning (2015) was implemented
336 in this study. Respondents were asked to use these scales to evaluate their perceptions about
337 wine produced by family and non-family wineries that they had purchased in the past year.

338 3.3 Analysis

339 Relationships among variables were implemented in lavaan version 0.5-23 to derive a
340 covariance-based structural equation model. Before implementing the structural model, scale
341 validity was ensured through computation of Cronbach's alpha (Cronbach, 1951), composite
342 reliability (CR; Raykov, 2001) and average variance extracted (AVE; Fornell & Larcker,
343 1981). Table 2 provides a summary of the three indicators for the latent variables of the study.

344 --- Table 2 here ---

345 One of the observed variables of the localness scale showed a strong negative effect
346 on scale reliability. Although the scale had been validated previously, exclusion of this item
347 led to improvement of scale reliability of the localness scale across all countries. The lowest
348 α -value was observed for the variable of behavioural loyalty in the Australian sample ($\alpha =$
349 $.73$). Moreover, CR (CR = $.73$) and AVE (AVE = $.57$) showed their lowest values in the
350 Australian sample for the given variable. This pattern held in the US sample ($\alpha = .79$,
351 CR = $.79$, AVE = $.65$). In the Italian sample, attitudinal loyalty exhibited the lowest values
352 with $\alpha = .80$, CR = $.80$ and AVE = $.67$. All given values were well above critical thresholds,
353 which are frequently defined as $\alpha > .70$ (Kline, 2015), CR $> .70$ and AVE $> .50$ (Bagozzi &
354 Yi, 1988). Multinormality of the data was assessed through the test statistics of skew and
355 kurtosis proposed by Mardia (1974) and Mardia (1970). Tests for skewness and kurtosis were
356 significant ($b_{1,36} = 78.35$, $z_{1,36} = 40,244.95$; $b_{2,36} = 1,974.34$, $z_{2,36} = 321.77$; and $p < .001$,
357 respectively), which led to a rejection of the assumption of multinormality. When considering
358 the distributional characteristics, despite the significance of both tests, modest skew and
359 kurtosis existed for the individual manifest variables. The prevalence of a significant but
360 modest non-normality was addressed through the computation of robust standard errors,
361 scaled test statistics and fit indices according to Satorra and Bentler (1994) and Li and Bentler

362 (2006). Through the adoption of these measures, maximum likelihood estimation remained
363 the preferred estimation method.

364 Scale invariance was assessed to be able to perform a singular estimation of the
365 structural model using the same measurement model. Table 3 shows the invariance tests for
366 the country group variable. A pooled model without the distinction of any groups exhibits a
367 favourable fit (comparative fit index (CFI) = .944, root mean square error of approximation
368 (RMSEA) = .059). When using the same structural model to estimate three individual models
369 at a country level, model fit was still well above the critical cut-off of CFI > .90 and RMSEA
370 < .08 (Hair, Black, Babin, & Anderson, 2013). To assess whether invariance held, $\Delta\text{CFI} < .01$
371 was used as a selection criterion because of the sensitivity of the χ^2 -statistic to sample size
372 (Cheung & Rensvold, 2002). The baseline scenario was represented by configural invariance,
373 which was represented by a joint estimation of the three models without parameter
374 constraints. When imposing the constraint of equal loadings between groups ($\Delta\text{CFI} = 0.002$,
375 weak invariance), the model fit did not violate the invariance condition. Further, equality of
376 intercepts was added as a further constraint ($\Delta\text{CFI} = 0.006$, strong invariance). Invariance still
377 held when using the ΔCFI -criterion. Finally, in addition, error variances were constrained to
378 equality to obtain strict invariance of the measurement models. Again, the invariance
379 condition was maintained after adding this further constraint ($\Delta\text{CFI} = 0.005$). Strict invariance
380 of the model implied that the indicator variables measured the same latent variables. This was
381 important to be able to perform a joint model estimation across the three countries (Davidov,
382 Meuleman, Cieciuch, Schmidt, & Billiet, 2014).

383 --- Table 3 here ---

385 4 Results

386 The first stage was to test how brand image elements are influenced by family firm
387 image and how they relate to brand trust and brand satisfaction. The results of the structural
388 model are shown by country in Table 4.

389 --- Table 4 here ---

390 First, it could be shown that not only family firm image—a measure of subjectively
391 perceived family firm status by respondents—positively affected any of the given brand
392 image element constructs, but also family firm status of a business was positively linked to
393 family firm image, leading to an acceptance of Hypothesis 1 regarding any of the three
394 countries under observation. Further, family firm image exercised a positive effect on
395 customer orientation, leading to validation of Hypothesis 2 in all three countries. The
396 hypothesised directional downstream relationship between customer orientation and brand
397 trust was consistently confirmed as well (Hypothesis 3). However, a positive effect of
398 customer orientation on brand satisfaction was only found in two countries (Australia and
399 Italy); hence, the results provided only partial support for Hypothesis 4.

400 Long-term orientation was a further variable positively influenced by family firm
401 identity in all three countries (Hypothesis 5); however, differences in the magnitude of this
402 effect were detected at $p = .06$. The positive effect of long-term orientation on brand trust
403 (Hypothesis 6), could only be partially confirmed in the three countries, and between-country
404 differences were observed ($p = .04$). The findings for the Italian sample were in line with the
405 hypothesis; however, no relationship could be established in the other two countries. The
406 relationship between long-term orientation and brand satisfaction was significant in all three
407 countries. Nevertheless, Hypothesis 7 is only partially supported, since this relationship
408 showed the expected positive sign only among the Italian sample, while in Australia and the
409 US samples the relationship was negative. Differences between the countries were significant
410 at $p = .00$.

411 Results from all three countries provided evidence that family firm image positively
412 influenced CSR. These findings support Hypothesis 8. CSR itself exercised a positive effect
413 on brand trust, hence supporting Hypothesis 9 regarding all three countries. Hypothesis 10,
414 which assumes a positive effect of CSR on brand satisfaction, is partially supported since a
415 significant positive relation could only be detected among the US sample.

416 In line with Hypothesis 11, a positive effect of family firm image on localness was
417 found, and differences with respect to the magnitude of this effect existed between countries
418 ($p = .06$). Further, localness was found to influence brand trust positively in the Australian
419 and Italian samples, while no effect could be found among US consumers, leading to a partial
420 confirmation of Hypothesis 12. The effect of localness on brand satisfaction was confirmed
421 across all three countries, as predicted in Hypothesis 13, while marginal evidence for
422 differences between the countries existed ($p = .10$).

423 The expected relationship between family firm image and perceived quality was
424 confirmed in all countries under consideration (Hypothesis 14); however, differences in the
425 magnitude of the hypothesised effect were detected at $p = .08$. The hypothesised positive
426 effect of perceived quality on brand trust was confirmed (Hypothesis 15), while between-
427 country differences were detected at $p = .08$. Similarly, perceived quality positively
428 influenced brand satisfaction in all three countries (Hypothesis 16), while showing significant
429 between-country differences ($p = .00$).

430 Social image was positively influenced by family firm image, which confirms
431 Hypothesis 17. Further, a significant positive effect of social image on brand trust was found
432 in the Italian sample. However, a negative effect of social image on brand trust was found in
433 the US sample, and no effect was detected in the Australian sample. These between-country
434 differences were significant at $p = .00$. Hence, Hypothesis 18 is only partially supported. An
435 inverted effect compared with evidence derived from literature was observed in all countries

436 regarding the relationship between social image and brand satisfaction, leading to a rejection
437 of Hypothesis 19.

438 Family firm image exercised a significant influence on uniqueness, validating
439 Hypothesis 20 equally regarding all three countries. However, no evidence in any country
440 could be found that supports the directional relationship between uniqueness and brand trust,
441 leading to a rejection of Hypothesis 21. Nevertheless, partial support was found for the
442 hypothesised relationship between uniqueness and brand satisfaction among the Italian and
443 US samples (Hypothesis 22), and differences between the countries were detected at $p = .09$.

444 With respect to behavioural outcomes, brand trust positively affected attitudinal
445 loyalty, which confirms Hypothesis 23 for all countries; however, significant differences
446 between countries were detected at $p = .02$. Further, Hypothesis 24 is supported through the
447 confirmation of a positive relationship between trust and behavioural loyalty. In all three
448 countries, brand satisfaction exercised a significant influence on attitudinal and behavioural
449 loyalty, thus confirming Hypotheses 25 and 26. Significant differences in the magnitude of
450 path coefficients were detected at $p = .00$ for the relationship of brand satisfaction with
451 attitudinal loyalty as well as for the relationship with behavioural loyalty ($p = .10$).

452 An analysis of latent means was conducted for the previously investigated constructs
453 at the country level to determine differences between family and corporate wineries for the
454 given constructs. As a first step, measurement invariance was established for the firm type
455 group variable for each of the three countries. The results show that strict invariance held for
456 all three countries. Table 5 illustrates the differences in latent means between both levels of
457 the firm type grouping variables for each country for the constructs of this study. Family firms
458 demonstrated consistently higher means of the latent variables than did corporate firms. Effect
459 sizes ranged from small ($d < .2$) to large ($d > .8$) effects for the individual constructs.

460 --- Table 5 here ---

5 Discussion

The results confirm earlier research in the field of marketing, such as brand relationship and loyalty, and reveal new linkages regarding how the distinctive family nature of a business is constituted (brand knowledge) and how this family nature links to the loyalty of consumers. This result is achieved through a newly proposed consumer-based brand equity framework that is specific to the nature of family firms. Thus, it contributes to a decoding of the multiple layers of this chain of effects. The individual aspects are discussed in the following paragraphs.

The path coefficients that are linked to the constructs of brand knowledge reveal several particularities that are important to discuss. First, and most importantly, all variables of brand knowledge were positively related to the construct of family firm image. However, the magnitude of individual path coefficients reveals differences between the countries. Since measurement invariance held, it can be constituted that the distinctive perception of family businesses shows idiosyncrasies between the individual countries. Consumer perceptions of family firms appear to have differed slightly with respect to constructs, such as the long-term orientation, localness, perceived quality and social image of these businesses. However, for any of the given constructs, the paths demonstrate a highly significant positive relationship leading to confirmation of any of the related hypotheses. More marked between-country differences with respect to the confirmation of the individual hypotheses emerged for the linkage between the individual brand image elements and how they affect behavioural outcomes.

The missing significance of an association between uniqueness and brand satisfaction among the Australian sample was unexpected, particularly since in Western cultures uniqueness conceptually is considered a desirable attribute that is linked to freedom and self-expression (Ruvio, 2008). A strong cultural grounding can be seen in the latent construct of

486 social image and its link to brand trust, which shows the expected positive link only in the
487 Italian sample. The magnitude and significance of the link can be considered to originate in
488 cultural dimensions. Particularly, individualism in a society may play a role. Following
489 Shukla (2010), the brands with high public status cultures may act as institutions with lower
490 degrees of individualism, such as in Italy in the given study. The link of social image to brand
491 satisfaction has shown an inverted effect to the one hypothesised. Higher social desirability of
492 a family brand appears to have a negative effect on satisfaction with the same. It is unclear
493 whether this negative effect derives from peer pressure–related strain; hence, further
494 investigation is necessary.

495 Perceived quality revealed different effects between the countries on brand
496 relationship constructs. Italy demonstrated the weakest linkage among the three countries for
497 both brand satisfaction and brand trust. This relative weakness may relate to the fact that
498 sophisticated consumer societies infer trust and satisfaction through a wider range of variables
499 than just plain product characteristics (Beckert et al., 2017). The relative weakness of this
500 variable in influencing both brand relationship constructs has to be understood in the context
501 of the two other variables of brand knowledge, namely localness and long-term orientation.
502 The Italian sample exhibited the strongest association of any of the countries between these
503 two variables and both constructs of brand relationship. The strong link to localness is
504 conceptually rooted in the ‘deep cultural value of Italian gastronomy and peasant traditions’
505 (Sassatelli & Scott, 2001, p. 224). Local production is also linked to traceability of food origin
506 and is the cornerstone of the European system of ‘protected designations of origin’. Similarly,
507 long-term orientation as a further construct showed differential effects between Old World
508 (Italy) and New World (Australia and US) countries in the sample. In Italy, long-term
509 orientation was a further relevant antecedent of brand trust and brand satisfaction (cf.
510 Kehagia, Chrysochou, Chrysochoidis, Krystallis, & Linardakis, 2007).

511 Path coefficients with both brand relationship variables showed a significant positive
512 association. However, in Australia and the US, long-term orientation did not influence brand
513 trust, and even negatively influenced brand satisfaction. Hence, in these countries long-term
514 orientation is overly linked to negative connotations, which may evolve from an association
515 with stasis and old-fashioned practices that fail to address consumer needs. Further, this
516 finding can be directly linked to the corresponding dimension of the culture score scale
517 developed by Hofstede, Hofstede and Minkov (2010), which supports the observed pattern in
518 the three countries. While no differences existed for the relationship between CSR and brand
519 trust among the tested countries, the relationship with brand satisfaction was mixed. Only
520 among the US sample was a significant positive relationship between the given variables
521 found. This finding provides insight into the mechanistic relationship regarding how CSR
522 affects consumer behaviour, which appears to show some dependence on cultural factors that
523 leads to differential behaviour of consumers in any of the three countries.

524 Finally, customer orientation has unambiguously been identified as a central
525 antecedent that influences brand trust in all three countries under investigation. One exception
526 existed in the relationship of this variable with brand satisfaction in the US sample, which
527 showed no significant positive effect, unlike the in two other countries. This fact may
528 originate in the lower prevalence of direct-to-consumer sales in the US (investigated but not
529 discussed in this manuscript). Nonetheless, an effect of customer orientation on behavioural
530 outcomes through an intermediate mediation via brand relation exists, and this underlines the
531 relevance of this latent construct for family businesses, which can generate additional value
532 through their unique relational qualities (Binz et al., 2013).

533 Similar to previous research in the field of marketing, this study has identified brand
534 relationship variables, such as brand trust and brand satisfaction, to show a significant
535 association with consumer loyalty. However, between-country differences indicate that brand

536 trust was a stronger driver of attitudinal loyalty in the Italian sample than in the other two
537 countries, while the link of brand satisfaction and attitudinal loyalty was stronger in the
538 Australian and US samples. These differences confirm an earlier study in the field of tourism
539 research by Forgas-Coll, Palau-Saumell, Sánchez-Garcia and Callarisa-Fiol (2012). The
540 observed differences between countries are not spurious but originate from the distinct
541 cultural characteristics of each country. Forgas-Coll et al. (2012) argue that high degrees of
542 culturally rooted individualism result in a strong pursuit of self-satisfaction and experience of
543 pleasure; hence, a stronger link between brand satisfaction and behavioural outcomes might
544 be expected. In fact, in this study, a stronger association of brand satisfaction and loyalty can
545 be observed in the Australian and US samples compared with the Italian sample. Referring to
546 Hofstede's (1980, 2001) scale, Wallenburg, Cahill, Michael Knemeyer and Goldsby (2011)
547 draw parallels between the magnitude of the trust–loyalty relationship with the cultural
548 dimension of uncertainty avoidance. This pattern was confirmed within the three countries
549 under investigation in this study. As expected, Italy, being the country with the highest score
550 for the dimension of uncertainty avoidance, exhibited the most marked path coefficient. It can
551 be constituted that consumers in cultures with a high degree of uncertainty avoidance feel
552 especially vulnerable in unstructured situations (Hofstede, 2011). Trust is known to be an
553 important element for reducing uncertainty that causes vulnerability (Chaudhuri & Holbrook,
554 2001, p. 82).

555 Further, the analysis of latent means revealed that family firms ranked higher for any
556 of the latent variables compared with their corporate counterparts. Customer orientation,
557 localness and CSR were shown to be the most distinctive variables overall, apart from the
558 family firm image variable, which was the most distinctive. However, it should be noted that
559 other variables, such as perceived quality, while they may have taken a lower rank, exhibited
560 a strong link with brand relationship variables. Hence, these variables represent a significant

561 antecedent in influencing consumer behaviour. More generally, it must be understood that not
562 all elements that have been found to differentiate family businesses from corporate ones show
563 any of the expected effects on consumer behaviour. This point is a critical one to understand
564 for practitioners because it clearly demonstrates that differentiation as an end in itself does not
565 necessarily lead to a competitive advantage in the marketplace. Nonetheless, this research
566 generates evidence that the vast majority of hypothesised elements that are found to
567 differentiate family firms lead to the goodwill of consumers in the marketplace. However, the
568 behavioural consequences that some brand image elements exercise depend on the cultural
569 context.

570 Important implications for the food and wine sector can be derived. Results of this
571 study show that the value of wine derives from a complex social process that adds further
572 value to the material act of production. Under the assumption of full information, actors in the
573 marketplace can fully assess the information cues related to the field of cultural production.
574 However, if information cost is assumed, market players may experience difficulties in
575 obtaining such information. In contrast, other market players possess a self-interest to use the
576 presence of such asymmetric information to obtain an advantage, which ultimately results in
577 market failure and adverse selection of product quality (Akerlof, 1970). In such situations,
578 principals' uncertainty about the intrinsic characteristics of agents can be reduced by reducing
579 information costs through certifications by trusted third parties. Further, principals can screen
580 agents through exogenous cost signals. Family firms can generate such signals in the
581 marketplace and reduce principals' uncertainty about the intrinsic characteristics of agents
582 through customer interaction with family members. These considerations have direct
583 implications for dedicated business models attached to such signalling that distinguish family
584 firms from their non-family counterparts.

585

6 Conclusion

586 This research provides important insights into the question of whether family firms are
587 perceived differently from their non-family counterparts and how such a perception
588 differential evolves from a customer perspective. A theory-driven framework has been
589 derived from past studies in the fields of marketing and family business research. The
590 framework introduces several advances in the field: For the first time, a comprehensive set of
591 brand image elements specific to family firms is modelled in an integrated customer-based
592 brand equity framework. In addition, this study adopts a dual perspective of consumer loyalty,
593 which related work in the field lacks. Third, results are validated across three countries for
594 increased robustness of findings.

595 Direct implications for different stakeholder groups can be derived based on the
596 research findings. First, the model validates and extends existing scientific marketing models
597 to the context of family firm research. Second, the first evidence regarding the cultural
598 interdependencies of detected relationships has been presented together with a proposed
599 theoretical explanation. Third, customer attitudes towards family firms provide further
600 guidance for policy makers, particularly when considering the social role of these firms and
601 the ways in which these firms create value. Similarly, practitioners, such as owners, managers
602 and consultants to family firms, can consider the findings of this research when defining the
603 strategic orientation of firms and their relationship towards consumers, who constitute one
604 key stakeholder group in many business contexts. The favourable perception of family firms
605 opens many avenues for market strategies, especially in an age of greatly decreasing
606 information costs. These developments equally constitute opportunities for family businesses
607 to reach out to new and existing customers. However, innovation and alignment of
608 communication strategies are required in this transforming market environment to prevent
609 family businesses becoming passive victims in this ongoing transformation process
610 (Chrisman, Chua, De Massis, Frattini, & Wright, 2015).

611 Although appropriate attention has been paid to the conduct of this study, limitations
612 apply. While consistent cultural patterns have been observed between the three countries, no
613 multivariate statistical analysis of cultural effects could be applied because of the limited
614 sample of only three countries. In addition, this research has only considered developed
615 countries, which constrains the applicability of implications to Western countries in
616 particular. It is therefore recommended that future research extends the results of the current
617 research by replicating this study for other countries and product categories, especially
618 categories that differ with respect to their hedonic or utilitarian qualities.
619
