#### Abstract

Since 2002, no clinical candidate against Alzheimer's disease has reached the market; hence, an effective therapy is urgently needed. We followed the so-called "multitarget directed ligand" approach and designed 36 novel tacrinephenothiazine heterodimers which were in vitro evaluated for their anticholinesterase properties. The assessment of the structure-activity relationships of such derivatives highlighted compound 1dC as a potent and selective acetylcholinesterase inhibitor with $\mathrm{IC}_{50}=8 \mathrm{nM}$ and 1 aA as a potent butyrylcholinesterase inhibitor with $\mathrm{IC}_{50}=15 \mathrm{nM}$. Selected hybrids, namely, $\mathbf{1 a C}$, $\mathbf{1 b C}, \mathbf{1 c C}, 1 \mathrm{dC}$, and $\mathbf{2 d C}$, showed a significant inhibitory activity  toward $\tau_{(306-336)}$ peptide aggregation with percent inhibition ranging from 50.5 to $62.1 \%$. Likewise, 1 dC and 2 dC exerted a remarkable ability to inhibit self-induced $\mathrm{A} \beta_{1-42}$ aggregation. Notwithstanding, in vitro studies displayed cytotoxicity toward HepG2 cells and cerebellar granule neurons; no pathophysiological abnormality was observed when 1 dC was administered to mice at $14 \mathrm{mg} / \mathrm{kg}$ (i.p.). 1dC was also able to permeate to the CNS as shown by in vitro and in vivo models. The maximum brain concentration was close to the $\mathrm{IC}_{50}$ value for acetylcholinesterase inhibition with a relatively slow elimination half-time. 1dC showed an acceptable safety and good pharmacokinetic properties and a multifunctional biological profile.

KEYWORDS: Alzheimer's disease, acetylcholinesterase, butyrylcholinesterase, phenothiazine, tacrine, multitarget directed ligands

## - INTRODUCTION

The etiology of Alzheimer's disease (AD) comprises intertwined mechanistic pathways which, for an effective therapeutic intervention, might be better addressed by a multitarget approach. ${ }^{1,2}$ This builds upon the fact that several targets can be simultaneously modulated by a single small molecule, i.e., a multitargeted directed ligand (MTDL). ${ }^{1}$ Developing MTDLs has represented a challenging task for many researchers around the world in the past couple of decades. ${ }^{3,4}$ Although reaching some preclinical successes, none of the developed MTDLs have been approved yet for the treatment of neurodegenerative diseases including $\mathrm{AD} .{ }^{5}$ Because different hypotheses of AD pathophysiology have been postulated, the appropriate target selection for the MTDL design is a matter of crucial importance. ${ }^{6,7}$

The so-called cholinergic hypothesis first attempted to explain the pathophysiological processes behind the $\mathrm{AD} .{ }^{8}$ Currently, cholinesterase inhibitors such as donepezil, galantamine, and rivastigmine are still one of the only two therapeutic options to temporarily improve cognitive function
and memory in AD patients. ${ }^{9}$ Amyloid plaques ${ }^{10,11}$ and neurofibrillary tangles composed of hyperphosphorylated $\tau$ protein ${ }^{12,13}$ are the two major AD hallmarks. Thus, several AD drug discovery programs have attempted to address these two targets, and first-in-class MTDLs have been developed for this purpose. ${ }^{14,15}$ In addition, several other hypotheses have emerged in recent years like those pointing to glutamate excitotoxicity, ${ }^{16}$ oxidative stress, ${ }^{17}$ and biometal dyshomeostasis ${ }^{18}$ as causative triggers of the underlying neurodegeneration. However, the impressive amount of knowledge regarding novel acetylcholinesterase (AChE) functions, as well as the close association between the cholinergic system and other key elements for AD pathogenesis, accounts for the fact that the

[^0]

Figure 1. Design strategy for tacrine-PHTs $\mathbf{1 - 3 ( a - d ) A - C . ~ G e n e r a l ~ s t r u c t u r e s ~ f o r ~ h i g h l y ~ e f f i c i e n t ~ n a p h t h o q u i n o n e - t a c r i n e ~ d e r i v a t i v e s ~ ( i n ~ p i n k - ~}$ dashed line) ${ }^{20}$ and for previously reported tacrine-PHTs (in green-dashed line) are outlined. ${ }^{40}$
development of multitarget cholinesterase inhibitors still has great potential. ${ }^{19}$

On these bases, we envisaged novel MTDLs by combining tacrine and phenothiazine (PHT) scaffolds (Figure 1). In detail, we were motivated by the promising results obtained for tacrine-naphthoquinone heterodimers linked through an alkylenediamine spacer (Figure 1), which were endowed with anticholinesterase, antiaggregating and antioxidant features, and a lower hepatotoxicity. ${ }^{20}$ Thus, following a similar rationale, we sought to combine the antiaggregating and antioxidant properties of the phenothiazine (PHT) core (see below) to the anticholinesterase effect of tacrine scaffold. Note that tacrine was the first marketed therapeutic agent for the AD treatment as a dual inhibitor of $\mathrm{AChE} /$ butyrylcholinesterase (BChE) enzymes. ${ }^{21}$ Upon tacrine withdrawal due to severe hepatotoxicity, 7-methoxytacrine (7-MEOTA) and 6-chlorotacrine emerged as the result of an intensive follow-up research in finding more potent ( 6 -chlorotacrine) and less toxic (7MEOTA) drug candidates. ${ }^{22,23}$
PHT is a tricyclic motif recurring in several drugs for neurological disorders, including promethazine for preoperative sedation or chlorpromazine for schizophrenia treatment. ${ }^{24,25}$ The PHT-based drugs chlorpromazine and fluphenazine are listed in the so-called "List of Essential Medicines 2017 (WHO)" for the treatment of psychotic disorders. ${ }^{24,26}$ Interestingly, chlorpromazine has displayed neuroprotective effects by protecting mitochondria and
preventing apoptosis and by promoting neuronal regeneration and survival. ${ }^{27,28}$ PHTs also possess a strong antioxidant capacity. ${ }^{29,30}$ We recently proposed a PHT-alkylamine as a privileged chemotype against neurodegeneration. ${ }^{31}$ Moreover, BChE inhibitory activity and selectivity over AChE of several PHT derivatives has already been reported. ${ }^{32,33}$ In addition, some of these drugs, including the well-known PHT dye methylene blue (MB), were found to be effective inhibitors of amyloid- $\beta$ peptide (A $\beta$ ) aggregation ${ }^{34}$ and $\tau$ filament formation. ${ }^{34} \mathrm{MB}$ emerged as a promising AD drug following the successful results of a phase II clinical trial performed with mild-to-moderate AD patients by TauRx Pharmaceuticals Ltd. ${ }^{35}$ In spite of these results and good outcomes from in vivo studies on animal models, leuco-methylthioniniumbis(hydromethanesulfonate), a derivative of MB , failed to slow down AD progression in the phase III clinical trial. ${ }^{34,36-38}$ However, this negative conclusion might be the result of a weak study design and statistical methodology, in addition to the lack of a proper placebo group. ${ }^{39}$

Collectively, it could be envisaged that MTDLs designed by combining tacrine and PHT scaffolds could bring interesting insights into AD treatment. The first attempt to link unsubstituted tacrine and PHT cores was made in 2014 by Hui et al. (Figure 1). ${ }^{40}$ However, only three compounds (with PHT-alkylamide structures) were synthesized and assayed on rat brain homogenate for their AChE inhibitory activity. They were further evaluated on okadaic-acid-induced phospho- $\tau$
accumulation in $\mathrm{N} 2 \alpha$ cells. The lead compound (1-(10H-phenothiazin-10-yl)-2-(\{6-[(1,2,3,4-tetrahydroacridin-9-yl)amino]hexyl $\}$ amino) ethan-1-one) was advanced for its ability to bind $\mathrm{A} \beta_{1-40}$ fibrils as determined by a surface plasmon resonance sensing assay. Overall, in addition to being a 89 nM potent inhibitor of rat AChE from rat brain homogenate, it proved to be effective in preventing $\tau$ phosphorylation and showed to be able to bind $\mathrm{A} \beta$ fibrils. ${ }^{40}$

In contrast and within this study, we significantly broadened the library of tested compounds while preserving the phenothiazine-alkylamine fragment. We expanded the chemical space by exploring methylene linkers of different lengths (ranging from 2 to 5 methylenes) connecting the two pharmacophores (a-d letters denote the length of the linker ranging from 2 to 5 carbons and designate the final structures). This length of the tether has been shown to impact AChE/ BChE recognition. More specifically, the shortest linker should yield BChE selectivity, while 3- and 4-methylene linkers should result in nonselective inhibitors; finally, the five-methylene linker might impose AChE preference. ${ }^{6,41-43}$ Furthermore, tacrine-PHT derivatives reported herein are based on three different tacrine fragments ( $\mathbf{A}, \mathbf{B}$, and $\mathbf{C}$ for tacrine, 7methoxytacrine (7-MEOTA), and 6-chlorotacrine, respectively), with different activities and toxicity profiles. In addition, variously substituted PHT cores were explored (1, 2, and 3 for PHT, 2-chlorophenothiazine, and 3-trifluoromethylphenothiazine, respectively), enabling the formation of 36 tacrine-PHTs (1-3(a-d)A-C; Figure 1). Herein, we describe their synthesis and in vitro evaluation, as well as the assessment of the preliminary in vivo profile. Initially, cholinesterase activity was assayed to draw structure-activity relationships (SARs). The effect of PHT moieties on biological activity was then evaluated by measuring antioxidant capacity, inhibition of $\tau_{(306-336)}$ peptide aggregation and inhibition of self-induced $\mathrm{A} \beta_{1-42}$ aggregation. Cytotoxicity and in vivo safety, together with in vitro BBB penetration of selected hybrids, were investigated.

## ■ RESULTS AND DISCUSSION

Chemistry. The synthetic route for tacrine-PHTs $\mathbf{1 - 3 ( a -}$ d) A-C started with the formation of the acetals $6,7,10$, and 12 (Scheme 1). These reactions were carried out as previously described (see Supporting Information, Schemes S1 and S2). ${ }^{31,44}$ Aldehyde 9 was prepared according to Jackson et al. ${ }^{45}$ and converted to acetal 10 by triethyl orthoformate treatment. Once the acetal intermediates were synthesized, the

Scheme 1. Preparation of Selected Acetals 6, 7, 10, and 12 ${ }^{a}$

[^1]subsequent reductive amination of $\mathbf{1 3 - 1 5}$ yielded the amide derivatives of PHT (16-27; Scheme 2). ${ }^{46}$ The subsequent hydrolysis of amides 16-27 enabled amine formation (28-39; Scheme 2) under three different procedures. In particular, the trifluoroacetamide protecting group of 16-21 was removed under mild conditions $\left(\mathrm{K}_{2} \mathrm{CO}_{3}\right)$ leading to the primary amines $\mathbf{2 8} \mathbf{- 3 3}$. Compounds $\mathbf{2 2 - 2 4}$ bearing an acetamide group were hydrolyzed using KOH under microwave (MW) irradiation allowing formation of 34-36. To obtain primary amines 3739, deprotection of phthalimides 25-27 was carried out using hydrazine hydrate. Finally, primary amines 28-39 were utilized as key starting material for the formation of the final products $\mathbf{1 - 3}(\mathbf{a}-\mathbf{d}) \mathrm{A}-\mathrm{C}$ by reaction with 9 -chloro-1,2,3,4tetrahydroacridine derivatives A-C in phenol under MW irradiation (Scheme 3). ${ }^{47}$

Cholinesterases Inhibitory Activity. The inhibition of both human AChE (hAChE) and human BChE (hBChE) by $\mathbf{1 - 3 ( a - d ) A}-\mathbf{C}$ was evaluated by a modified Ellman method. ${ }^{48}$ Results (Table 1) confirmed that all the compounds were potent cholinesterase inhibitors. Compounds displayed anticholinesterase activity spanning from the micromolar to nanomolar scales (nanomolar activity was displayed by derivatives 1dA, 1dC, and 2dC for hAChE; 1aA, 1aC, 2aA, $\mathbf{2 a C}, 3 \mathrm{aA}, 1 \mathrm{cA}-\mathrm{C}, 1 \mathrm{dA}, 2 \mathrm{dA}$, and 3dA for $h \mathrm{BChE}$ ) and showed a clear influence by substituents and linkers. In detail, strong inhibitory activity toward hAChE was obtained for compounds bearing a five-methylene tether (1-3dA or 13dC), with the exception of 7-MEOTA-based heterodimers $\mathbf{1 d B}, \mathbf{2 d B}$, and 3 dB . In contrast, compounds bearing the shortest two-carbon linker ( $1-3 \mathrm{aA}-\mathrm{C}$ ) were the most potent toward hBChE . Similar results have been already reported for other heterodimers/homodimers such as bis-tacrines or tacrine-based MTDLs with different linkers. ${ }^{6,41,42,49}$ It might be inferred that the chain length is important to properly accommodate the PHT nucleus which, being bulky and rigid, may generate some steric clashes. When the chain length is composed by four or five carbon atoms, the PHT moiety presumably better approaches the peripheral anionic site at the mouth of hAChE. This enhances the selectivity and affinity toward this enzyme. Conversely, because the gorge of $h \mathrm{BChE}$ is shorter and nearly double in size compared to that of $h A C h E,{ }^{50}$ the interaction of tacrine-PHTs featuring a shorter alkylene chain is favored. Hence, for hybrids with shorter linkers, selectivity is shifted toward $h \mathrm{BChE} .{ }^{50,51}$ Generally, most active derivatives toward $h \mathrm{BChE}$ and $h \mathrm{AChE}$ bear a twomethylene ( $\mathbf{1}-3 \mathrm{aA}-\mathrm{C}$ ) and five-methylene ( $\mathbf{1}-3 \mathrm{dA}-\mathrm{C}$ ) chain, respectively. In agreement with the higher inhibitory potency of 6 -chlorotacrine vs tacrine on hAChE , the derivatives bearing such a fragment $(\mathbf{1} \mathbf{- 3}(\mathbf{a}-\mathbf{d}) \mathrm{C})$ were more potent $\left(\mathrm{IC}_{50}=8-\right.$ $1500 \mathrm{nM})$ than tacrine analogues $\left(\mathbf{1} \mathbf{- 3}(\mathbf{a}-\mathbf{d}) \mathrm{A}_{;} \mathrm{IC}_{50}=0.08-\right.$ $13.1 \mu \mathrm{M}$ ). Similarly, those bearing a 7-MEOTA fragment ( $1-$ $3(\mathbf{a}-\mathrm{d}) \mathrm{B}$ ) were the least potent against $h \mathrm{AChE}$ enzyme ( $\mathrm{IC}_{50}$ $>0.6 \mu \mathrm{M})$. No clear SAR could be drawn for PHT moiety when dealing with hAChE inhibition. Only 2 -trifluoromethyl ( $\mathbf{3}(\mathbf{a}-\mathrm{d}) \mathbf{A}-\mathbf{C})$ derivatives appeared to be slightly less efficient than the 2 -chloro- $(\mathbf{2}(\mathbf{a}-\mathbf{d}) \mathrm{A}-\mathbf{C})$ or unsubstituted PHTs $(\mathbf{1}(\mathrm{a}-\mathrm{d}) \mathrm{A}-\mathrm{C})$. The $h \mathrm{BChE}$ activity is improved in subsets with 2 -trifluoromethyl ( $\mathbf{3}(\mathbf{a}-\mathrm{d}) \mathrm{A}-\mathrm{C}$ ) and diminishes in 2chloro derivatives $(\mathbf{2}(\mathbf{a}-\mathbf{d}) \mathbf{A}-\mathbf{C})$ followed by unsubstituted PHTs ( $\mathbf{1}(\mathbf{a}-\mathbf{d}) \mathbf{A}-\mathbf{C}) . \mathbf{1 d C}$ was highlighted as the best inhibitor of $h \mathrm{AChE}\left(\mathrm{IC}_{50}=8 \mathrm{nM}\right)$ with a selectivity index toward $h \mathrm{AChE}$ of 24 . In addition, $\mathbf{1 a A}$ was selected as the best

$h \mathrm{BChE}$ inhibitor $\left(\mathrm{IC}_{50}=19 \mathrm{nM}\right)$ with a selectivity index toward $h \mathrm{BChE}$ around 100 .

Both cholinesterases are distributed within the brain areas (hippocampus, temporal neocortex, and amygdala) ${ }^{52,53}$ connected with memory functions, speech creation, and recall of memories. However, while AChE is mostly localized in the synaptic cleft between neurons, BChE is mainly found in the glial cells. Alterations in AChE and BChE expression occur in $\mathrm{AD} .{ }^{54} \mathrm{AChE}$ plays a predominant role in the brain of healthy subjects, in which it acts as the main actor in the hydrolysis of the neurotransmitter acetylcholine (ACh); however, AChE activity decreases with the progression of $\mathrm{AD} . \mathrm{BChE}$ is able to hydrolyze ACh and can compensate for AChE when its levels are lowered. It has also been reported that BChE might slow down the formation of neurotoxic $\mathrm{A} \beta$ fibrils in vitro. ${ }^{55}$ However, the connection between BChE and $\mathrm{A} \beta$ fibrils/ amyloid plaques remains quite controversial. On one hand,
researchers showed that some variants of BChE are able to attenuate amyloid fibril formation in vitro; ${ }^{56,57}$ on the other hand, recent in vivo experiments demonstrated that BChE may play a role in AD plaque maturation. ${ }^{58}$ For the abovementioned reasons, the hypothesis that BChE-selective or $\mathrm{BChE}-$ nonselective inhibitors are more efficient in preventing amyloid aggregation cannot be unequivocally postulated.

A kinetic study was performed to determine the inhibition mechanism of compounds $\mathbf{1 d A}$ and $\mathbf{1 d C}$, selected on the basis of the most pronounced cholinesterase inhibition properties. Inhibition kinetics were elucidated from velocity curves which were measured at several concentrations of tested compounds and substrate. The type of enzyme inhibition and kinetic parameters ( $K_{\mathrm{i}}$ and $K_{\mathrm{i}}^{\prime}$ ) were determined using nonlinear regression analysis. Results for each type of model of inhibition (competitive, noncompetitive, uncompetitive, and mixed) were compared by the sum-of-squares F-test. Statistical analysis

${ }^{a}$ The results are expressed as the mean of at least three experiments. ${ }^{b}$ Selectivity for $h \mathrm{AChE}$ is determined as the ratio of $h \mathrm{BChE} \mathrm{IC} 50 / h \mathrm{AChE} \mathrm{IC}{ }_{50}$; ${ }^{c}$ Data taken from ref 49. ${ }^{d}$ Data taken from ref 42.
showed a mixed-type mode of inhibition with hAChE for 1dC and a mixed-type inhibition for $h \mathrm{BChE}$ for 1dA ( $p<0.05$ ), which is consistent with the Lineweaver-Burk plot, used for visualization of obtained data (Figure 2). This finding confirms that all tested derivatives are reversible cholinesterase inhibitors.
For the derivative 1dC, the intersection of lines is placed above the $x$-axis, indicating a mixed-mode of hAChE
inhibition, meaning a reversible binding mode to both the free enzyme and enzyme-substrate complex, with higher affinity to the free enzyme $\left(K_{\mathrm{i}}<K_{\mathrm{i}}^{\prime}\right) . K_{\mathrm{m}}$ was increased, and $V_{\max }$ was reduced at a higher concentration of the inhibitor. $\mathbf{1 d C}$ has an affinity to the free $h \mathrm{AChE}$ and enzyme-substrate complex.

In the case of $h \mathrm{BChE}$, the intersection of lines is above the $x$ axis for 1dA, which shows a mixed-type inhibition, meaning a

Figure 2. Steady-state inhibition of $h \mathrm{AChE}$ and $h \mathrm{BChE}$ substrate hydrolysis by compounds $\mathbf{1 d C}$ and $1 \mathbf{d A}$ at different concentrations. Lineweaver-Burk plots of initial velocity at increasing substrate concentrations ( $h \mathrm{AChE}=0.16-1.25 \mathrm{mM} ; h \mathrm{BChE}=2.5-20.0 \mathrm{mM}$ ) are presented. Lines were derived from a linear regression of the data points.
reversible binding mode to both the free enzyme and enzymesubstrate complex, with higher affinity to the free enzyme ( $K_{i}<$ $\left.K_{\mathrm{i}}^{\prime}\right) . K_{\mathrm{m}}$ was slightly increased, and $V_{\max }$ was reduced at a higher concentration of both inhibitors.
The $K_{\mathrm{i}}$ value of $6.7 \pm 2.0 \mathrm{nM}$ and $K_{\mathrm{i}}^{\prime}$ value of $15.5 \pm 2.7 \mathrm{nM}$ were determined for $\mathbf{1 d C}$ for $h \mathrm{AChE}$. For 1dA, the $K_{\mathrm{i}}$ value of $6.2 \pm 1.6 \mathrm{nM}$ and $K_{\mathrm{i}}^{\prime}$ value $19.4 \pm 2.6 \mathrm{nM}$ were found for $h \mathrm{BChE}$.

HepG2 Cytotoxicity, Antioxidant Activity, and In Vitro Estimation of the BBB Penetration. According to $h \mathrm{AChE} / h \mathrm{BChE}$ inhibitory activities, 12 compounds were selected for further analysis. Attention was also paid to preserve structural diversity among the three tacrine subsets as well as the PHTs while accounting for the tether length. Cell viability was assessed on a liver hepatocellular carcinoma (HepG2) cell line using the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetraziolium bromide) reduction assay. ${ }^{59}$ Measurement of compounds' cytotoxicity was carried out after 24 h incubation. All selected tacrine-PHTs exerted a rather higher cytotoxicity $\left(\mathrm{IC}_{50}\right.$ values from 5.6 to $\left.13.5 \mu \mathrm{M}\right)$ compared to that of the reference tacrine and PHT (Table 2). This might be associated with increased molecular weight and lipophilicity. A similar trend has already been discussed recently, and it does not reflect or give any clear prospect for the in vivo toxicological profile. ${ }^{49,60-62}$ Importantly, the most active hybrids exerted their activities in a low nanomolar range which is 3 orders of magnitude lower than calculated $\mathrm{IC}_{50}$ cytotoxicity values.
For a preliminary assessment of the antioxidant properties of the hybrids, we employed the operationally simple and widely used DPPH method. ${ }^{63}$ No DPPH scavenging activity was found in this family; only PHT itself exerted weak antioxidant activity (Table S1). Loss of activity may be attributed to the $N$ alkylation of the PHT core, as this assay is based on the principle that the DPPH radical, by accepting a hydrogen atom from the scavenger molecule, is reduced to the DPPH-H form with a resulting decrease in absorbance. Thus, a secondary amine is necessary to preserve PHT antioxidant properties in this assay. This is in line with previously reported data pointing out that $N$-unsubstituted PHT derivatives were more efficient than those with amide groups. ${ }^{30}$
Furthermore, four selected hybrids (1bC, 1dC, 2dA, and 2dC) were evaluated in vitro for their potential ability to cross the blood-brain barrier (BBB) using the cell monolayer based on a Madin-Darby Canine Kidney (MDCK) cell line as a model of BBB. On the basis of the achieved results, all tested compounds were predicted to enter the CNS (Table 2).

Table 2. Cytotoxicity of Tested Compounds in HepG2 Cells after 24 h and the MDCK Determination for Potential BBB Penetration

$a_{\text {n.t. }}=$ not tested. ${ }^{b}$ The results are expressed as the mean of a minimum of three experiments; BBB penetration measurements predict that the test compounds have the potential to passively pass the BBB. Papp values correspond to those of standard drugs with high CNS permeability. ${ }^{c}$ Data taken from ref 64 .

Inhibition of $\tau_{(306-336)}$ Peptide Aggregation. In the human brain, the $\tau$ protein exists in different isoforms which share a common third repeat domain (R3, residues 306-336). Mutagenesis studies have highlighted that the R3 domain plays a role in inducing $\tau$ aggregation, ${ }^{65}$ and it is able to induce aggregation of the microtubule-binding region of $\tau$ in cells. ${ }^{66}$ Based on these considerations, $\tau$ peptide 306-336 $\left(\tau_{(306-336)}\right)$ is a suitable self-assembly model of the microtubule-binding domain in $\tau$ protein. ${ }^{67}$ The in vitro aggregation of this $\tau$ fragment can be used to enable the preliminary prioritization of potential $\tau$ inhibitors.

Hybrids containing the 6 -chloro-tacrine moiety were selected to be assayed, because the most potent hAChE inhibitor (1dC) belongs to this subseries. Analogues with a shorter linker chain were included in the study to assess the effect of the linker chain length on $\tau_{(306-336)}$ peptide aggregation. Finally, the analogue of derivative $\mathbf{2 d C}$ bearing a chloro-substituent at the PHT moiety was also assayed being the second most potent $h \mathrm{AChE}$ inhibitor among the tacrinePHT hybrids under investigation.

Inhibition experiments were performed by incubating $\tau_{(306-336)}$ peptide at $50 \mu \mathrm{M}$ in the presence of selected hybrids (1:1 ratio). Formation of $\tau$ fibrils was monitored by using thioflavin T (ThT) as fluorescence probe. ${ }^{14}$ Fluorescence intensity was scanned every 10 min for 16 h . Estimation of the inhibitory potency (\%) was carried out by comparing fluorescence values at the plateau in the presence and in the absence of the inhibitor.

All selected hybrids significantly inhibited $\tau_{(306-336)}$ aggregation with differences falling in a narrow range (from
50.5 to $62.1 \%)$ at $50 \mu \mathrm{M}$, while neither tacrine nor PHT were able to significantly interfere with $\tau_{(306-336)}$ aggregation (Figure $3)$. Based on the results, our conclusion is that the chain length

Figure 3. Averaged fluorescence profile of $\tau_{(306-336)}$ peptide aggregation in the absence (black line) and in the presence of 1 cC (gray line); $\tau_{(306-336)}$ and $\mathbf{1 c C}$ were both at $50 \mu \mathrm{M}$, at 1:1 ratio. Fibril formation was monitored using ThT as fluorescent dye. $\lambda$ exc $=446$ $\mathrm{nm}, \lambda \mathrm{m}=490 \mathrm{~nm}$. Results are based on three independent experiments.
influences the inhibitory potency, with optimal values being two or three methylene units. Introduction of a chlorine atom at the PHT moiety does not significantly affect the antiaggregating properties (compare activity of derivatives $\mathbf{1 d C}$ and 2dC) (Table 3).

Table 3. Antiaggregating Properties of Selected TacrinePHT Hybrids toward $\boldsymbol{\tau}_{(306-336)}$ Self-Aggregation

|  | inhibition of $\tau(306-336)$ |
| :--- | :---: |
| compound | peptide self-aggregation $(\%) \pm$ <br> SEM $^{a}$ |
| $\mathbf{1 a C}$ | $55.6 \pm 1.8$ |
| $\mathbf{1 b C}$ | $62.1 \pm 5.4$ |
| $\mathbf{1 c C}$ | $61.1 \pm 0.3$ |
| $\mathbf{1 d C}$ | $50.5 \pm 1.7$ |
| $\mathbf{2 d C}$ | $51.9 \pm 0.6$ |
| tacrine | $\sim 5$ |
| phenothiazine | $<5$ |

${ }^{a}$ The results are the mean of at least two independent measurements each performed in triplicate. $\tau_{(306-336)}$ and tested compounds were both at $50 \mu \mathrm{M}$, at 1:1 ratio.

Of note, all selected derivatives were able not only to reduce the amount of fibril formed (lower the fluorescence value at the plateau) but also to significantly delay (by about $1.5-2 \mathrm{~h}$ ) the exponential phase of the aggregation profile (see Figure 3, aggregation profiles in the absence and the presence of $\mathbf{1 c C}$, the most potent inhibitor among those assayed, as representative example) which can likely be attributed to a stabilization of the starting $\beta$-sheet conformer of the $\tau$ fragment.

Inhibition of Self-Induced $\mathrm{A} \boldsymbol{\beta}_{1-42}$ Aggregation. Because the formation of $\mathrm{A} \beta$ oligomers and their accumulation into amyloid plaques is still considered as a triggering point in AD , there is a demand for the development of effective anti- $\mathrm{A} \beta$ drugs. ${ }^{68}$ It is known that $\beta$-sheet-rich aromatic residues of $\mathrm{A} \beta$ play a pivotal role in the self-aggregation process; thus, aromatic-containing compounds should be able to intermolecularly recognize these regions and prevent aggregation via $\pi$ -
stacking interactions. ${ }^{69-71}$ This phenomenon has already been confirmed in some MB and PHT derivatives. ${ }^{34}$ Thus, compounds $\mathbf{1}(\mathbf{a}-\mathbf{d}) \mathbf{C}$ and $\mathbf{2 d C}$ were selected and were evaluated for their ability to inhibit self-induced $\mathrm{A} \beta_{1-42}$ aggregation (at an inhibitor/ $\mathrm{A} \beta$ ratio of $1 / 1,50 \mu \mathrm{M}$ concentration, similar to $\tau_{(306-336)}$ peptide aggregation assay). Tacrine and PHT were selected as parent compounds, and MB and doxycycline were used as positive references. The aggregation of amyloidogenic isoform $\mathrm{A} \beta_{1-42}$ was inspected by a ThT-based fluorescence assay, which allows for the monitoring of amyloid fibril formation. ${ }^{72}$

According to the obtained results, the length of the linker proved to be crucial for anti-A $\beta$ properties in a comparable manner to previous findings. ${ }^{73,74}$ This accounts for five methylene tethered heterodimers ( $\mathbf{1 d C}$ and $\mathbf{2 d C}$ ) showing excellent inhibitory potency ( $\%$ inhibition $>70 \%$ ). Conversely and interestingly, short-chained derivatives $(\mathbf{1}(\mathbf{a}-\mathbf{c}) \mathbf{C})$ were not active (Table 4). Anti-A $\beta$ property in $\mathbf{1 d C}$ and $\mathbf{2 d C}$ might

Table 4. Inhibition of $\mathrm{A} \boldsymbol{\beta}_{1-42}$ Aggregation Produced by the Tested Compounds at $50 \mu \mathrm{M}$ Concentration ( $1 / 1$ Ratio with Amyloid)

${ }^{a}$ Inhibition of $\mathrm{A} \beta_{1-42}$ aggregation was measured in the presence of compounds in the ratio $A \beta_{1-42} /$ compound $1: 1$ at $50 \mu \mathrm{M}$. ${ }^{b}$ The results are the mean of three independent measurements each performed in duplicate. ${ }^{c}$ n.a. stands for not active; i.e., no significant inhibition was observed at compound concentration of $50 \mu \mathrm{M}$.
be attributed to (i) improved ligand flexibility and (ii) a longer spacer between two pharmacophores (five methylenes) that can allow for the contacting of two parallel $\beta$-strands of $\mathrm{A} \beta_{1-42} ;{ }^{75}$ however, further research is needed to prove this hypothesis. Both highlighted compounds (1dC and 2dC) showed superior activity to tacrine and PHT, further justifying the tacrine-PHT combination. On the other hand, neither 1dC nor 2 dC reached the efficacy of MB , which was able to completely inhibit $\mathrm{A} \beta$ aggregation at $50 \mu \mathrm{M}$, a datum that is consistent to other studies. ${ }^{76}$

Neurotoxicity in Primary Rat CGNs. The data collected so far made 1dC and 2dC an interesting starting point on multiple fronts by acting as cholinesterase $/ \tau$-aggregation $/ \mathrm{A} \beta$ aggregation inhibitors that cross the BBB. To further evaluate the potential of these PHT-tacrine hybrids, neurotoxicity against primary cultures of cerebellar granule neurons (CGNs) was tested. Following an experimental protocol we recently applied for analogous PHT derivatives, ${ }^{31}$ compounds were tested at $5 \mu \mathrm{M}$ concentration, and viability was assessed by using two different readouts, i.e., MTT and condensed (apoptotic) nuclei counting using Hoechst fluorescent dye. Intriguingly, whereas both compounds reduced viability over $50 \%$ in the MTT ( $5 \mu \mathrm{M}$; Figure 4), only a $33 \%$ reduction for $\mathbf{1 d C}$ and a $15 \%$ reduction for 2 dC of cell death were observed

Figure 4. Neurotoxicity of $\mathbf{1 d C}$ and $\mathbf{2 d C}$ on primary rat CGNs after 24 h treatment. Results are expressed as percentage of controls and are the mean $\pm \mathrm{SE}$ of three experiments, in quadruplicate. $* * p<0.01$ compared to control conditions $(0 \mu \mathrm{M})$ using one-way ANOVA and Bonferroni's posthoc test.
microphotographically after Hoechst staining (Figure 5). Importantly, the neurotoxicity profile revealed by fluorescent

Figure 5. Live cell counting following Hoechst staining to test the toxicity of $\mathbf{1 d C}$ and $\mathbf{2 d C}$ compounds toward differentiated CGNs after 24 h treatment. Results are expressed as percentage of live cell counting following Hoechst staining. Results are the mean $\pm$ SE of five images. $* * p<0.01 * * * p<0.001$ compared to control CGNs, Student's $t$ test.
staining of the condensed or fragmented nuclei assay mirrors that of chlorpromazine, a widely used CNS-directed drug. ${ }^{31}$ The data obtained suggest that the MTT assay may produce false negative results when used to examine the viability of cells treated with PHT-based hybrids on this cell line.

Safety Evaluation and Verification of Brain Distribution In Vivo. Considering the relatively low neurotoxicity profile together with strong anticholinesterase activity, good $\tau$ antiaggregating properties, and predicted capability to cross the BBB, we continued with 1dC in vivo testing. The reason to perform such an evaluation with 1dC would be to provide a more clear outlook, specifically because (i) the mechanism
underlying the hepatotoxicity of tacrine has not yet been fully elucidated and because (ii) the toxicity mechanism of tacrine might not be translated to the synthesized hybrids, which impose a novel chemotype. Preliminary safety and brain distribution studies were performed on Balb/c mice. Notably, no clinical sign of toxicity was observed in control mice as well as in 1dC-treated mice. Necropsy revealed no macroscopic pathology of internal organs of the chest and abdominal cavity. Blood biochemistry (Table 5) as well as histopathological examination of intestine and mesentery, liver, and kidneys did not show any abnormalities. Positively, while tacrine has been reported to induce elevation in serum alanine aminotransferase (ALT) activity, which is indicative of hepatic injury in $30-50 \%$ of the patients, ${ }^{62}$ this biomarker was not altered upon $\mathbf{1 d C}$ administration. Thus, the administered dose of $14 \mathrm{mg} / \mathrm{kg}$ (i.p.) can be considered safe for further in vivo experiments.

The maximal concentration of hybrid 1dC in plasma was achieved 30 min after i.p. administration; in subsequent time intervals, a gradual decrease was observed. The maximal brain concentration was also reached after $30 \mathrm{~min}(6.6 \mathrm{nM})$ and was relatively stable for all time intervals (Table 6) up to 120 min .

Table 6. In Vivo BBB Permeability Estimation of 1 dC in Mice ${ }^{a}$

|  | blood |  | brain |  | ratio |
| :---: | :---: | :---: | :---: | :---: | :---: |
| time (min) | nM |  | nM |  | $\%$ |
| 30 | $417 \pm 46$ |  | $6.6 \pm 1.7$ |  | 1.6 |
| 60 | $274 \pm 56$ |  | $3.7 \pm 0.4$ |  | 1.3 |
| 120 | $205 \pm 21$ |  | $4.9 \pm 0.6$ |  | 2.4 |

${ }^{a}$ Results are expressed as mean $\pm$ SEM, $n=4$.

In light of these data and those related to the inhibitory activity against $h \mathrm{AChE}\left(\mathrm{IC}_{50} 8.0 \pm 0.4 \mathrm{nM}\right)$ and the selectivity index (Table 1), hybrid 1dC should be able to inhibit AChE at the central level. The relatively low elimination from the brain tissue suggests a potential for accumulation after repeated administration as in the case of tacrine. ${ }^{77}$

## CONCLUSIONS

In summary, 36 novel hybrids were prepared by a facile threestep synthesis. Screening for cholinesterase inhibitory activity revealed that all the compounds were efficient inhibitors of cholinesterase enzymes with activities ranging from the micromolar to one-digit nanomolar scales. Activity and selectivity depended on the type of tacrine fragment (either unsubstituted, chloro-derivative, or methoxy-derivative) and the length of the linker used to connect the two pharmacophore units, highlighting the two-methylene linker for $h \mathrm{BChE}$-selective compounds and the five-methylene linker for hAChE-selective compounds. No clear SAR for substituents at the PHT fragment could be drawn, thus considering that these do not play a key role in the modulation of the inhibitory potency toward either cholinesterase. Of note, 7-MEOTA and 2 -trifluoromethyl-PHT derivatives always

Table 5. Selected Biochemical Parameters Assessed in Blood Plasma 24 h after Administration of Hybrid 1dC ${ }^{a}$

|  | glucose $(\mathrm{mg} / \mathrm{dL})$ | urea $(\mathrm{mg} / \mathrm{dL})$ | creatinine $(\mu \mathrm{g} / \mathrm{dL})$ | ALT (U/L) | AST (U/L) | ALP (U/L) | amylase (U/L) |

[^2]resulted in a poor-to-moderate inhibitory activity. The hybrids bearing an unsubstituted PHT and tacrine or 6-chlorotacrine moieties showed the highest $\mathrm{AChE} / \mathrm{BChE}$ activity. Specifically, 1dC was the most effective and selective hAChE inhibitor with $\mathrm{IC}_{50}=8 \mathrm{nM}$, while 1 aA was the most potent and selective $h \mathrm{BChE}$ inhibitor with $\mathrm{IC}_{50}=15 \mathrm{nM}$. Of note, inhibitory activity toward AChE by $\mathbf{1 d C}$ is comparable to that of the drug donepezil. Importantly, 6-chlorotacrine hybrids $\mathbf{1}(\mathbf{a}-\mathbf{d}) \mathbf{C}$ and 2dC not only inhibited $\tau_{(306-336)}$ peptide aggregation but also significantly delayed the exponential phase of aggregation. Furthermore, the remarkable ability to inhibit self-induced $\mathrm{A} \beta_{1-42}$ aggregation was found for compounds 1 dC and 2 dC . Notwithstanding the new hybrid's affected cell viability when tested on HepG2 cells and cerebellar granule neurons (MTT readout), no pathophysiological abnormality was observed after i.p. administration of 1 dC to mice at $14 \mathrm{mg} / \mathrm{kg}$. Hence, in vivo experiments showed that $\mathbf{1 d C}$ was relatively safe, and it was able to permeate the BBB and inhibit the brain AChE. Further in vivo experiments to fully understand the therapeutic potential of $\mathbf{1 d C}$ as a multitarget-directed ligand for AD are warranted.

## - METHODS

Chemistry. General Synthetic Methods. The column chromatography was performed using silica gel 100 and Sigma-Aldrich silica gel grade $9385,60 \AA, 230-400$ mesh at atmospheric pressure. The analytical thin-layer chromatography (TLC) was carried out using 0.20 mm silica gel 60 F254 plates (Merck, Germany), which were visualized by exposure to ultraviolet light ( 254 nm ) and phosphomolybdic acid (PMA) and bromocresol green (BCG) stains. The NMR spectra were recorded on a Varian S500 spectrometer ( 500 and 126 MHz ) and on a Varian VXR $400\left(400 \mathrm{MHz}\right.$ for ${ }^{1} \mathrm{H}$ and 100 MHz for ${ }^{13} \mathrm{C}$ ). Chemical shifts are reported in $\delta$ parts per million (ppm) referenced to an internal $\mathrm{SiMe}_{4}$ standard for ${ }^{1} \mathrm{H}$ NMR and $\mathrm{CDCl}_{3}-d\left(\mathrm{CHCl}_{3}-d l ; 7.26\right.$ (D); 77.16 (C) ppm), $\mathrm{CD}_{3} \mathrm{OD}\left(\mathrm{CH}_{3} \mathrm{OH}-\right.$ dl; 3.35, 4.78 (D), 49.3 (C) ppm), or hexadeuteriodimethyl sulfoxide (DMSO-d6; 2.50 (D), 39.7 (C) ppm). Chemicals were purchased from Sigma-Aldrich Co. LLC and were used without additional purification. CEM Explorer SP 12 S Class was used for microwave irradiation. The final compounds were analyzed by LC-MS consisting of UHLPC Dionex Ultimate 3000 RS coupled with a Q Exactive Plus orbitrap mass spectrometer (Thermo Fisher Scientific, Bremen, Germany) to obtain high resolution mass spectra. Gradient LC analysis confirmed $>95 \%$ purity.
5-(1,3-Dioxo-2,3-dihydro-1H-isoindol-2-yl)pentanal (9). (A) 5-Amino-1-pentanol (8; 33.93 mmol ) and phthalic anhydride ( 33.93 mmol ) were added into the oven-dried round-bottom flask. The mixture was stirred at $145{ }^{\circ} \mathrm{C}$ under Ar atmosphere for 30 min . The resulting residue, with no need of further purification, was dried on vacuum pump affording 5 -(1,3-dioxo-2,3-dihydro- 1 H -isoindol-2-yl)pentanol as a light yellow oil with quantitative yield. ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}-d\right): \delta 7.86-7.81(\mathrm{~m}, 2 \mathrm{H}), 7.73-7.69(\mathrm{~m}, 2 \mathrm{H}), 3.70(\mathrm{t}, J$ $=7.2 \mathrm{~Hz}, 2 \mathrm{H}), 3.64(\mathrm{t}, J=6.5 \mathrm{~Hz}, 2 \mathrm{H}), 1.78-1.67(\mathrm{~m}, 2 \mathrm{H}), 1.67-$ $1.57(\mathrm{~m}, 2 \mathrm{H}), 1.48-1.38(\mathrm{~m}, 2 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta$ $168.45,133.85,132.08,123.14,62.57,37.81,32.14,28.31,22.99$. (B) $(\mathrm{COCl})_{2}(40.72 \mathrm{mmol})$ was added to anhydrous DCM $(60 \mathrm{~mL})$ containing DMSO ( 74.65 mmol ) at $-45{ }^{\circ} \mathrm{C}$ under Ar atmosphere. After the mixture was stirred for $5 \mathrm{~min}, 5$-(1,3-dioxo-2,3-dihydro- 1 H -isoindol-2-yl)pentanol ( 33.93 mmol ) dissolved in anhydrous DCM was added dropwise. After the mixture was stirred for another 15 min , diisopropylethylamine (DIPEA; 101.79 mmol ) was added portionwise. The reaction was cooled to $-30^{\circ} \mathrm{C}$ and stirred for an additional 30 min . Finally, the solvent was removed, and the residue was diluted with EA allowing for the formation of a white precipitate which was removed by filtration. The filtrate was washed once with 150 mL of $6 \% \mathrm{NaHCO}_{3}$ and three times with 150 mL of $\mathrm{H}_{2} \mathrm{O}$. The organic layer was dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated affording 9 as a
light red oil. Yield $=77 \%$ after two steps. ${ }^{1} \mathrm{H}$ NMR ( 500 MHz , $\left.\mathrm{CDCl}_{3}-d\right): \delta 9.73(\mathrm{~s}, 1 \mathrm{H}), 7.84-7.77(\mathrm{~m}, 2 \mathrm{H}), 7.73-7.66(\mathrm{~m}, 2 \mathrm{H})$, $3.68(\mathrm{t}, J=6.8 \mathrm{~Hz}, 2 \mathrm{H}), 2.51-2.45(\mathrm{~m}, 2 \mathrm{H}), 1.76-1.60(\mathrm{~m}, 4 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta$ 201.80, 168.32, 133.93, 132.01, 123.18, 43.15, 37.39, 27.93, 19.19.

2-(5,5-Diethoxypentyl)-2,3-dihydro-1H-isoindole-1,3-dione (10). Compound 9 ( 5.01 mmol ) and $p$-toluenesulfonic acid monohydrate ( 0.05 mmol ) were dissolved in absolute EtOH under Ar atmosphere. The solution was further bubbled with Ar. Then, triethyl orthoformate ( 5.01 mmol ) was slowly added, and the mixture was stirred and bubbled with Ar for 3 h at RT. EtOH was evaporated, and the residue was diluted with $\mathrm{DCM}(70 \mathrm{~mL})$ and saturated with $\mathrm{NaHCO}_{3}(100 \mathrm{~mL})$. The mixture was extracted three times with DCM ( $3 \times 70 \mathrm{~mL}$ ), and the organic layers were collected, dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and filtered off. The filtrate was concentrated under reduced pressure and purified by column chromatography (PE/ $\mathrm{EA}=5: 1$ ) affording 10 as a colorless oil. Yield $=74 \%$. ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}-d\right): \delta 7.86-7.81(\mathrm{~m}, 2 \mathrm{H}), 7.73-7.68(\mathrm{~m}, 2 \mathrm{H}), 4.47(\mathrm{t}, J$ $=5.7 \mathrm{~Hz}, 1 \mathrm{H}), 3.69(\mathrm{t}, J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 3.66-3.59(\mathrm{~m}, 2 \mathrm{H}), 3.52-$ $3.44(\mathrm{~m}, 2 \mathrm{H}), 1.76-1.62(\mathrm{~m}, 4 \mathrm{H}), 1.46-1.38(\mathrm{~m}, 2 \mathrm{H}), 1.23-1.14$ (m, 6H). ${ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta$ 168.35, 133.80, 132.14, 123.11, 102.66, 61.03, 37.88, 33.14, 28.38, 22.06, 15.29.

Preparation of Phenothiazine Intermediates 16-27. In the dried round-bottom flask, 6, 7, 10, or $12(2.4 \mathrm{mmol})$ and 13,14 , or 15 (2 mmol ) were dissolved in dry DCM ( 20 mL ) under nitrogen atmosphere. Trifluoroacetic acid (TFA; 26 mmol ) and triethylsilane (TES; 5 mmol ) was then added dropwise, and the reaction mixture was stirred for 2 h at room temperature. Then, the reaction mixture was cooled to $0^{\circ} \mathrm{C}$ and slowly neutralized with addition of saturated $\mathrm{NaHCO}_{3}$ (until $\mathrm{pH}=7-8$ ). The mixture was extracted with DCM 3 $\times 20 \mathrm{~mL}$. The organic layers were collected, dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and filtered. The filtrate was concentrated under reduced pressure and purified by column chromatography affording 16-27.

N-[2-(10H-Phenothiazin-10-yl)ethyl]-2,2,2-trifluoroacetamide (16). The resulting residue was purified by column chromatography ( $\mathrm{PE} / \mathrm{EA}=9: 1$ ) affording 16 as a dark yellow viscous oil. General Procedure for the Hydrolysis of Trifluoroacetamides 16-21 to Primary Amines 28-33. Compounds 16-21 (1.5 mmol) and $\mathrm{K}_{2} \mathrm{CO}_{3}(12 \mathrm{mmol})$ were dissolved in the mixture of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ $2: 1(12+6 \mathrm{~mL})$. The mixture was stirred overnight at room temperature. The solvents were evaporated, and the precipitate was diluted with $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ and extracted with DCM $(3 \times 20 \mathrm{~mL})$. The organic layers were collected, dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and
filtered. The filtrate was concentrated under reduced pressure to afford 28-33 without any need for further purification.

2-(10H-Phenothiazin-10-yl)ethan-1-amine (28). This compound is a dark yellow viscous oil with yield $=88 \%$. ${ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}-d\right): \delta 7.22-7.08(\mathrm{~m}, 4 \mathrm{H}), 7.03-6.83(\mathrm{~m}, 4 \mathrm{H}), 3.99(\mathrm{t}, J=5.9$ $\mathrm{Hz}, 2 \mathrm{H}), 3.06(\mathrm{t}, J=5.9 \mathrm{~Hz}, 2 \mathrm{H}), 1.45(\mathrm{bs}, 2 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( 100 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 145.22,127.59,127.23,125.88,122.69,115.77$, 50.52, 38.85 .

2-(2-Chloro-10H-phenothiazin-10-yl)ethan-1-amine (29). This compound is a dark purple viscous oil with quantitative yield $\% .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}-d$ ): $\delta 7.23-7.10(\mathrm{~m}, 2 \mathrm{H}), 7.10-7.03(\mathrm{~m}$, $1 \mathrm{H}), 7.01-6.80(\mathrm{~m}, 4 \mathrm{H}), 3.96(\mathrm{t}, J=5.9 \mathrm{~Hz}, 2 \mathrm{H}), 3.06(\mathrm{t}, J=5.9 \mathrm{~Hz}$, 2 H ), 1.29 (bs, 2H).

2-[2-(Trifluoromethyl)-10H-phenothiazin-10-yl]ethan-1-amine (30). 3-[2-(Trifluoromethyl)-10H-phenothiazin-10-yl]propan-1-amine (36). The resulting residue was purified by column chromatography $\left(\mathrm{DCM} / \mathrm{MeOH} / \mathrm{NH}_{3}(33 \%\right.$ aq sol $\left.)=14: 1: 01\right)$ affording 36 as a yellow viscous oil. Yield $=85 \% .{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}-d\right): \delta$ $7.20-7.01(\mathrm{~m}, 4 \mathrm{H}), 6.99-6.84(\mathrm{~m}, 3 \mathrm{H}), 3.97(\mathrm{t}, J=6.6 \mathrm{~Hz}, 2 \mathrm{H})$, $3.31(\mathrm{t}, J=6.6 \mathrm{~Hz}, 2 \mathrm{H}), 2.10(\mathrm{p}, J=6.6 \mathrm{~Hz}, 2 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR $(100$ $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 145.67,144.34,129.77,127.61,127.43,127.32$,
123.92, 122.99, 118.94, 115.98, 112.05, 112.01, 48.00, 44.86, 29.11, 27.63.

General Procedure for the Hydrolysis of Phthalimides 25-27 to Primary Amines 37-39. Compounds 25-27 ( 2.0 mmol ) were dried in a round-bottom flask and dissolved in absolute EtOH under Ar atmosphere. Hydrazine hydrate ( $50-60 \%$ solution in $\mathrm{H}_{2} \mathrm{O} ; 1.0 \mathrm{~mL}$ ) was slowly added, and the mixture was heated to reflux $\left(90^{\circ} \mathrm{C}\right)$ and kept stirred under Ar overnight ( 16 h ). The next day, the white precipitate was filtered and washed with EtOH . The filtrate was concentrated under reduced pressure and purified by column chromatography affording products $37-39$.

5-(10H-Phenothiazin-10-yl)pentan-1-amine (37). The resulting residue was purified by column chromatography ( $\mathrm{DCM} / \mathrm{MeOH} / \mathrm{NH}_{3}$ $(25 \% \mathrm{aq} \mathrm{sol})=9: 1: 0.1)$ affording 37 as a light yellow viscous oil. Yield $=82 \% .{ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}-d\right): \delta 7.18-7.11(\mathrm{~m}, 4 \mathrm{H}), 6.94-$ $6.89(\mathrm{~m}, 2 \mathrm{H}), 6.89-6.83(\mathrm{~m}, 2 \mathrm{H}), 3.91-3.81(\mathrm{~m}, 2 \mathrm{H}), 2.73-2.63$ $(\mathrm{m}, 2 \mathrm{H}), 2.07(\mathrm{bs}, 2 \mathrm{H}), 1.87-1.76(\mathrm{~m}, 2 \mathrm{H}), 1.51-1.41(\mathrm{~m}, 4 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 145.23,127.41,127.13,125.04,122.34$, 115.40, 47.08, 41.73, 32.67, 26.61, 24.08.

5-(2-Chloro-10H-phenothiazin-10-yl)pentan-1-amine (38). The resulting residue was purified by column chromatography (DCM/ $\mathrm{MeOH} / \mathrm{NH}_{3}(25 \%$ aq sol $)=$ 9:1:0.1) affording 38 as a light yellow viscous oil. Yield $=74 \% .{ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}-d\right): \delta 7.19-7.11$ $(\mathrm{m}, 2 \mathrm{H}), 7.04-7.00(\mathrm{~m}, 1 \mathrm{H}), 6.96-6.91(\mathrm{~m}, 1 \mathrm{H}), 6.91-6.87(\mathrm{~m}$, $1 \mathrm{H}), 6.87-6.83(\mathrm{~m}, 1 \mathrm{H}), 6.84-6.79(\mathrm{~m}, 1 \mathrm{H}), 3.83(\mathrm{t}, J=7.0 \mathrm{~Hz}$, $2 \mathrm{H}), 2.69(\mathrm{t}, J=6.5 \mathrm{~Hz}, 2 \mathrm{H}), 2.11(\mathrm{bs}, 2 \mathrm{H}), 1.85-1.76(\mathrm{~m}, 2 \mathrm{H})$, $1.54-1.41(\mathrm{~m}, 4 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 146.54,144.50$, $133.15,127.88,127.50,127.35,124.82,123.57,122.84,122.18$, 115.74, 47.22, 41.69, 32.51, 26.49, 24.03.

5-[2-(Trifluoromethyl)-10H-phenothiazin-10-yl]pentan-1-amine (39). The resulting residue was purified by column chromatography $\left(\mathrm{DCM} / \mathrm{MeOH} / \mathrm{NH}_{3}(25 \%\right.$ aq. sol. $\left.)=9: 1: 0.1\right)$ affording 39 as a light yellow viscous oil. General Procedure for the Coupling of N-Alkylated Phenothiazine with 9-Chloro-1,2,3,4-tetrahydroacridine Derivatives. Compounds 28-39 ( 0.20 mmol ) and 9-chloro-1,2,3,4-tetrahydroacridines $\mathbf{A}-\mathbf{C}(0.22 \mathrm{mmol})$ were melted and dissolved in phenol $(0.3 \mathrm{~mL})$ by heating gun at $90^{\circ} \mathrm{C}$ in the microwave-sealed tube. The mixture was then subjected to microwave irradiation $(150 \mathrm{~W})$ at $180^{\circ} \mathrm{C}$ for 90 min . The reaction mixture was diluted with 20 mL of DCM and a $20 \%$ solution of $\mathrm{KOH}(20 \mathrm{~mL})$, following extraction with additional DCM $(3 \times 20 \mathrm{~mL})$. The organic layers were collected, dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and filtered. The filtrate was concentrated under reduced pressure and purified by column chromatography affording products $1-3(\mathrm{a}-\mathrm{d}) \mathrm{A}-\mathrm{C}$.

N-[2-(10H-Phenothiazin-10-yl)ethyl]-1,2,3,4-tetrahydroacridin9 -amine (1aA). The resulting residue was purified by column chromatography (PE/DCM/Tol/EtOH/ $\mathrm{NH}_{3}$ (33\% aq sol) $=$ 15:6:3:1:0.1) affording 1 aA as a yellow viscous oil. LC-MS purity > $97 \%$.

Biology. Primary Rat CGNs. CGNs were prepared from 7-day-old Wistar rats as described ${ }^{31}$ and plated at the density of $1.2 \times 10^{5}$ cells/ well on 96 -well plates previously coated with $10 \mu \mathrm{~g} / \mathrm{mL}$ poly L-lysine (Sigma-Aldrich, Milano, Italy). The medium used for the culture was BME with $10 \%$ heat-inactivated Fetal bovine serum (FBS, Aurogene, Rome, Italy), 2 mM glutamine (Aurogene, Rome, Italy), $100 \mu \mathrm{M}$ gentamicin sulfate (Sigma-Aldrich, Milano, Italy), and 25 mM Potassium chloride (KCl, Sigma-Aldrich, Milano, Italy). After 16 h, $10 \mu \mathrm{M}$ cytosine arabino-furanoside (Sigma-Aldrich, Milano, Italy) was added to avoid glial proliferation. After 7 days in vitro, the cells were exposed to compounds $1 \mathbf{d C}$ and $\mathbf{2 d C}$ at different concentrations ( 0 , $0.5,1,2$, and $5 \mu \mathrm{M})$ in serum-free BME medium. Cell viability was evaluated by MTT assay after 24 h of treatment. Statistical data analysis was performed through GraphPad Prism 4 by using one-way ANOVA followed by Bonferroni's posthoc comparison test.

Live Cell Counting after Hoechst Staining. Differentiated CGNs were exposed to $\mathbf{1 d C}$ and $\mathbf{2 d C}$ compounds at $5 \mu \mathrm{M}$ for 24 h in serumfree medium. Cells were fixed for 20 min with $4 \%$ PFA in phosphate buffer, washed in PBS, and incubated with $0.1 \mu \mathrm{~g} / \mathrm{mL}$ of Hoechst 33258 (Sigma-Aldrich, Milano, Italy) for 5 min at room temperature. Five randomly fields were acquired from each sample by using a fluorescence microscope ( $20 \times$ objective; Nikon Eclipse TE 2000-S microscope, equipped with an AxioCam MRm digital camera). Live cells were counted by using the manual cell counter plugin of Fiji Image J2 software.
$\tau_{(306-336)}$ Pretreatment. $\tau_{(306-336)}(1 \mathrm{mg})$ (Bachem AG, Weil am Rhein, Germany) was initially dissolved in 1,1,1,3,3,3,-hexafluoro-2propanol (HFIP), gently vortexed, sonicated, and kept overnight at room temperature. Subsequently, the sample was aliquoted, dried, and stored at $-20^{\circ} \mathrm{C}$.
$\tau_{(306-336)}$ Peptide Aggregation and Its Inhibition by ThT Fluorimetric Assay. Stock solutions of $\tau_{(306-336)}$ peptide ( $500 \mu \mathrm{M}$ ) were prepared in ultrapure water and immediately used. Stock solution of $\mathrm{ThT}(500 \mu \mathrm{M})$ was prepared in 56.3 mM phosphate buffer ( $\mathrm{PB}, \mathrm{pH}=7.4$ ), while stock solutions of inhibitors $(20 \mathrm{mM})$ and of the reference compounds tacrine and phenothiazine ( 10 mM ) were prepared in DMSO/methanol 10/90. $\tau_{(306-336)}$ aggregation was monitored at $30^{\circ} \mathrm{C}$ in a black, clear-bottom 96 -well plate (Greiner) by EnSpire multiplate reader (PerkinElmer, Waltham, Massachusetts, USA) using ThT fluorimetric assay ${ }^{14}$ with some variations. The excitation and emission wavelengths were set at 446 and 490 nm , respectively. Assay samples were prepared by diluting $\tau_{(306-336)}$ stock solution to $50 \mu \mathrm{M}$ in the assay mixture which consisted in $20 \mu \mathrm{M}$ ThT, 48.1 mM PB (final concentrations) in a final $100 \mu \mathrm{~L}$ volume (final DMSO and MeOH content: $0.05 \%$ and $0.45 \%$, respectively). Inhibition experiments were performed by incubating $\tau_{(306-336)}$ peptide at the given conditions in the presence of tested inhibitors at $50 \mu \mathrm{M}$. Fluorescence data were recorded every 10 min overnight with 1 min of shaking at 800 rpm prior to each reading. Each inhibitor was assayed in triplicate in at least two independent experiments. Estimation of the inhibitory potency (\%) was carried out by comparing fluorescence values at the plateau (average fluorescence intensity value in the $12-16 \mathrm{~h}$ range). Inhibition $\%$ values are expressed as the mean $\pm$ SEM. Quenching of ThT fluorescence was evaluated by preparing blank solutions containing inhibitor/reference compound and preformed fibrils of $\tau_{(306-336)}$ peptide.
$A \beta_{1-42}$ Inhibition Assay. Stock solutions of tested inhibitors were prepared in DMSO and diluted in 10 mM PBS containing 150 mM
$\mathrm{NaCl}(\mathrm{pH}=8)$ to the final concentration in the well $(50 \mu \mathrm{M})$. Thioflavin T (ThT, final concentration $20 \mu \mathrm{M}$ ) was added to the well after it was dissolved in methanol and subsequently diluted in 50 mM glycine $-\mathrm{NaOH}(\mathrm{pH}=8.6)$ to 0.4 mM . Finally, $\mathrm{A} \beta_{1-42}$ (HFIP-treated, BACHEM) was added to reach the $50 \mu \mathrm{M}$ final concentration per well. Initially, 1 mg of $\mathrm{A} \beta_{1-42}$ was dissolved in DMSO to obtain the stock solution and stored at $-20^{\circ} \mathrm{C}$. Before the assay, $\mathrm{A} \beta_{1-42}$ stock solution was briefly sonicated and vortexed and added to the 96 -well plate as the last component. The final volume of the assay mixture was $100 \mu \mathrm{~L}$. $\beta_{1-42}$ self-aggregation was performed at room temperature without any stirring in a black, clear-bottom 96 -well plate (Greiner) by a multiplate reader (Synergy HT, Biotek, Winooski, Vermont, United States) using ThT fluorimetric assay. The excitation and emission wavelengths were set at $440 / 30$ and $485 / 20 \mathrm{~nm}$, respectively. Inhibition experiments were monitored by incubating $\mathrm{A} \beta_{1-42}$ at the given conditions in the presence or absence of the tested compound. Doxycycline and methylene blue ( $50 \mu \mathrm{M}$ ) were used as reference inhibitors; parent compounds tacrine e PHT were also evaluated. Fluorescence emission was recorded every 10 min during 72 h incubation time without any stirring. Each inhibitor was assayed in duplicate in two independent experiments. The presented values were averaged and are expressed as the mean $\pm$ SEM (the standard error of the mean). The ratio according to eq 1 was calculated after subtraction of fluorescence of unbound ThT

$$
\begin{equation*}
R=\frac{F_{\mathrm{plateau}}-F_{\mathrm{lag}}}{F_{\mathrm{lag}}} \tag{1}
\end{equation*}
$$

where $F_{\text {lag }}$ and $F_{\text {plateau }}$ are fluorescence intensities of A $\beta_{1-42}$ in lag and plateau phases of the aggregation kinetic at five time points every 30 $\min$, respectively. After that, the percent inhibition of $\mathrm{A} \beta_{1-42}$ aggregation was calculated as follows (eq 2):

$$
\begin{equation*}
\% \text { inhibition }=100-\left(\frac{R_{I}}{R_{0}}\right) \times 100 \tag{2}
\end{equation*}
$$

where $R_{\mathrm{I}}$ and $R_{0}$ are ratios according to eq 1 with or without studied compounds, respectively.

## Author Contributions

L.G. and E.U. handled chemical synthesis and manuscript writing. E.M. handled chemical synthesis. M.B. handled anti- $\tau$
properties and manuscript writing. J.J. handled anti- $\tau$ properties. M.H. and V.H. handled anticholinesterase activity and DPPH. L.P. handled HRMS, LC-MS, and in vivo analysis. L.M. handled HepG2 cytotoxicity. J.P. and J.Z.K. handled in vivo studies. T.K. and O.S. handled the in vitro BBB permeation assay. S.P. and B.M. handled the neurotoxicity assay. J.K. and M.L.B. handled the manuscript writing and experiment supervision.

## Notes

The authors declare no competing financial interest.

## ■ ACKNOWLEDGMENTS

The study was supported by a grant from the Ministry of Defence "Long Term Development Plan" Medical Aspects of Weapons of Mass Destruction of the Faculty of Military Health Sciences, University of Defence; by the Ministry of Education, Youth and Sports of Czech Republic (project ERDF no. CZ.02.1.01/0.0/0.0/18_069/0010054); and by the Grant from the Czech Science Foundation (20-29633J). Marvin was used for drawing, displaying, and characterizing chemical structures, substructures, and reactions (Marvin 17.21.0, ChemAxon, https://www.chemaxon.com). The abroad internship for LG was supported by the Faculty of Military Health Sciences, University of Defence (Czech Republic, Long-term development plan). M.L.B. and M.B. would also like to acknowledge the University of Bologna and the Italian Ministry for Education, Universities and Research (MIUR), for the financial support.
