Chronic exposure to aluminium (Al) can contribute to the progression of several neurological and neurodegenerative diseases. Al is a metal that promotes oxidative damage leading to neuronal death in different brain regions with behavior, cognition, and memory deficits. Chrysin is a flavonoid found mainly in honey, passion fruit, and propolis with antioxidant, anti-inflammatory, and cytoprotective properties. In this study, we used an integrated approach of *in vitro* and *in vivo* studies to evaluate the antioxidant and neuroprotective effects of chrysin against the neurotoxicity elicited by aluminium chloride (AlCl₃). In *in vitro* studies, chrysin (5 μM) showed the ability to counteract the early oxidative stress elicited by tert-butyl hydroperoxide, an oxidant that mimics the lipid peroxidation and Fenton reaction in presence of AlCl₃ as well as the late necrotic death triggered by AlCl₃ in neuronal SH-SY5Y cells. *In vivo* studies in a mouse model of neurotoxicity induced by chronic exposure to AlCl₃ (100 mg/kg/day) for ninety days then corroborated the antioxidant and neuroprotective effect of chrysin (10, 30, and 100 mg/kg/day) using the oral route. In particular, chrysin reduced the cognitive impairment induced by AlCl₃ as well as normalized the acetylcholinesterase and butyrylcholinesterase activities in the hippocampus. In parallel, chrysin counteracted the oxidative damage, in terms of lipid peroxidation, protein carbonylation, catalase, and superoxide dismutase impairment, in the brain cortex and hippocampus. Lastly, necrotic cells frequency in the same brain regions was also decreased by chrysin. These results highlight the ability of chrysin to prevent the neurotoxic effects associated with chronic exposure to Al and suggest its potential use as a food supplement for brain health.

Keywords: Aluminium; neurotoxicity, oxidative stress; antioxidant; chrysin.

1. Introduction

Aluminum (Al) is the third most abundant element in the earth's crust and occurs naturally in the environment, foodstuffs, and drinking water. According to the European Food Safety Authority (EFSA), the human tolerable weekly intake is 1 mg Al/kg body weight (BW) in a 60-kg adult. However, in some individuals this intake is exceeded as a result of estimated daily alimentary aluminum exposure of 1.6–13 mg (0.2–1.5 mg/kg BW/week) (Klotz et al., 2017).

The toxic effects of this metal occur through its accumulation over time and several sources contribute to Al exposure in humans, such as industrial areas (0.04 to 1.4 mg/m³/day), natural water (different cities around the world have reported concentrations as high as 0.4–2.7 mg/L), foods (3–11 mg/kg/day), drugs such as antacid (104–208 mg of Al per tablet) and aspirin (10–20 mg of Al per tablet), and cosmetics (10.98–694.5 mg/kg in lipsticks) (Krewski et al., 2007; Exley, 2013; Borowska & Brzóska, 2015).

Among the different forms of Al, the ionic form of Al³⁺ can exert various cytotoxic effects through its ability to induce the formation of reactive oxygen species, oxidative damage, and neuronal death (Willhite et al., 2014). Al³⁺ can also cross the blood-brain barrier and accumulate in various human brain regions, suggesting the contribution of Al to the progression of neurological and neurodegenerative diseases, including Alzheimer's disease (AD), dialysis dementia syndrome, autism spectrum disorder, multiple sclerosis, and epilepsy (Lukiw et al., 2018; Exley and Mold, 2019). In this regard, the chronic accumulation of Al in the brain induces deregulation of gene expression in neurons, gliosis, neuronal death, and functional decline resulting in deficits in cognition, memory, and behavior (Lukiw et al., 2018).

Although Al is a low redox metal, considerable evidence supports its pro-oxidant activity at the brain level (Maya et al., 2016; Garza-Lombó et al., 2018). Al can bind to brain phospholipids, which contain polyunsaturated fatty acids vulnerable to the oxidizing action of

1 reactive oxygen species (ROS), including hydrogen peroxide (H₂O₂), superoxide (O₂⁻), and
2 hydroxyl (OH[·]) radical (Yuan et al., 2012). In particular, Al can strengthen the iron (Fe²⁺)-
3 initiated lipid peroxidation in the Fenton reaction, which causes Fe³⁺ formation and ROS
4 production. Further, O₂⁻ is neutralized by Al³⁺ to form an Al-O₂⁻ complex, which increases
5 the oxidative capacity of O₂⁻ (Ruipérez et al., 2012). In this context, the neurobehavioral
6 deficits, such as defects in memory and motor functions, elicited by chronic exposure to Al
7 also reflect the ability of this metal to promote oxidative stress and neurodegeneration in brain
8 regions rich in polyunsaturated fatty acids, including the cortex and hippocampus (Drobovshev
9 et al., 2018; Farhat et al., 2019). Recent studies also show a cross talk between oxidative stress
10 and neuroinflammation in neurodegeneration elicited by Al chronic exposure (Maya et al.,
11 2016). The neuroinflammatory response triggered by oxidative stress can contribute to
12 cognitive impairments through neuropathological and neurochemical changes in the cortex and
13 hippocampus (Fernandes et al., 2020).

31 The use of natural antioxidants as potential therapeutics is a challenging area of
32 neuroscience research (Tal et al., 2016). Among natural antioxidants, the chrysin is a flavonoid
33 (5,7-dihydroxyflavone) found mainly in mushrooms (*Lactarius deliciosus* - 0.17 mg/kg, *Suillus*
34 *bellinii* - 0.34 mg/kg), passion fruit (*Passiflora ocreata* - 40 mg/mL, *Passiflora edulis*, and
35 *Passiflora caerulea* L. - 0.012 - 0.25 mg/mL), propolis (28 mg/mL), and in honey (e.g. honey
36 of honeydew - 0.10 mg/kg, and forest honeys- 5.3 mg/kg) (Hadjmohammadi et al., 2010;
37 Kalogeropoulos et al., 2013; Nabavi et al., 2015; El-Askary et al., 2017; Mani and Natesan,
38 2018). In addition, marketed tablets/capsules may include 300-800 mg of chrysin (Nabavi et
39 al., 2015; Manzolli et al., 2015; Mohos et al., 2018; Mohos et al., 2020).

1 Sairazi et al., 2017). These evidences suggest the ability of natural antioxidants present in
2 honey and propolis, such as chrysin, to cross the blood-brain barrier (BBB) and affect the
3 oxidative stress on the central nervous system (CNS) level. In this regard, an *in silico* approach
4 to predict the pharmacokinetics of chrysin by the SwissADME web tool reveal its good overall
5 drug-likeness profile including high gastrointestinal absorption and BBB permeant (Daiana
6 and Zoete, 2016; Daiana et al., 2016).
7

8
9 Chrysin showed antioxidant and neuroprotective effects against cognitive decline in a
10 rat model of diabetes and neurodegeneration induced by 6-hydroxydopamine in a mouse model
11 of Parkinson's disease (Li et al., 2014; Manzolli et al., 2015; Nabavi et al., 2015). However, the
12 neuroprotective effects of chrysin against the neurotoxicity evoked by Al remain unknown.
13

14 In this study, we used an *in vitro* experimental approach to evaluate: 1) the antioxidant
15 effects of chrysin against the oxidative stress induced by various oxidants and Fenton reaction
16 promoted by aluminium chloride (AlCl₃) in neuronal SH-SY5Y cells, as well as the ability of
17 chrysin to counteract both the oxidative stress and inflammation evoked by lipopolysaccharides
18 (LPS) in microglial THP-1 cells; 2) the neuroprotective effects of chrysin against the
19 neurotoxicity in terms of cytostatic effects and necrosis elicited by AlCl₃ in neuronal SH-SY5Y
20 cells; 3) we, then, assessed the antioxidant and neuroprotective activity of chrysin in a mouse
21 model of neurotoxicity induced by chronic exposure to AlCl₃. Chrysin was administered to
22 mice using the oral route to explore its potential use as a food supplement for brain health.
23

24 **2. Materials and Methods**

25 **2.1 Chemicals**

26 AlCl₃, iron sulfate (FeSO₄), chrysin (97% purity - Fig. 1), hydrogen peroxide (H₂O₂),
27 tert-butyl hydroperoxide (t-BuOOH), acetylthiocholine (ATCh), 2,2'-azinobis-(3-
28 ethylbenzothiazoline-6-sulfonic acid) (ABTS•+), butyrylthiocholine (BTCh), 2-7-

1 dichlorodihydrofluorescein diacetate (H2DCF-DA), 5,5'-dithiobis-(2-nitrobenzoic acid)
2 (DTNB), malondialdehyde (MDA), epinephrine bitartrate, 2,4-dinitrophenylhydrazine
3 (DNPH), sodium dodecyl sulfate (SDS), eosin, hematoxylin, and serum albumin (BSA) were
4 obtained from Sigma Chemical (St. Louis, MO, USA). All other chemicals were obtained in
5 an analytical grade or from standard commercial suppliers.

1 concentrations of chrysin (1.25 – 40 μM) for 24 h at 37°C in 5% CO₂. The cell viability, in
2 terms of mitochondrial metabolic function, was evaluated by the reduction of 3-(4,5-dimethyl-
3 2-thiazolyl)-2,5-diphenyl2H-tetrazolium bromide (MTT) to its insoluble formazan. The
4 treatment was replaced with MTT in HBSS [0.5 mg/mL] for 1 h at 37°C in 5% CO₂. After
5 washing with HBSS, formazan crystals were dissolved in isopropanol. The amount of formazan
6 was measured (570 nm, reference filter 690 nm) using a multilabel plate reader (VICTOR™
7 X3, PerkinElmer, Waltham, MA, USA). The quantity of formazan was directly proportional to
8 the number of living cells. Data are expressed as percentages of neuronal viability with control
9 taken as 100% viability.

24 **2.2.5 Anti-inflammatory activity in microglial THP-1 cells**

25 The anti-inflammatory activity of chrysin in microglial THP-1 activated by LPS was
26 performed as previously described by Di Martino et al., 2020. Briefly, THP-1 cells were seeded
27 in 60 mm dishes at 2.5×10^6 cells/dish, incubated for 24 h with PMA (10 $\mu\text{g}/\text{mL}$) and
28 subsequently, treated for 24 h with chrysin (5 μM) and LPS (1 $\mu\text{g}/\text{mL}$). Afterward, the cell
29 suspension was pelleted, and RNA was extracted by the PureLink RNA Mini Kit (Life
30 Technologies, Carlsbad, CA, USA) according to the manufacturer's guidelines. A total of 1 μg
31 of RNA were used to synthesize cDNA using the SuperScript VILO MasterMix (Invitrogen,
32 Carlsbad, CA, USA). Quantitative RT-PCR was carried out using SYBR Select Master Mix
33 (Invitrogen), and relative normalized expression was calculated by comparing the cycle
34 threshold (Ct) of the target gene (Inducible nitric oxide synthase, iNOS; Interleukin 1 beta; IL-
35 1 β ; Tumour Necrosis Factor-alpha; TNF- α) to that of the reference genes β -Actin and
36 glyceraldehyde-3-phosphate dehydrogenase protein (GAPDH, Life Technologies). All
37 reactions had three technical replicates, and each condition had three biological replicates.

Relative quantification was calculated according to the $\Delta\Delta C_t$ method ($2^{-\Delta\Delta C_t}$) with untreated cells as control. Primer sequences used in this study are listed in Table 1.

2.2.6 Neuroprotective activity in neuronal SH-SY5Y cells

The neuroprotective activity of chrysin was evaluated in neuronal SH-SY5Y cells in terms of cytostatic effect and necrosis using trypan blue and propidium iodide (PI), respectively, as previously described by Pruccoli et al., 2020. Cells were seeded in 60 mm dishes at 1×10^6 cells/dish, incubated for 24 h, and subsequently treated for 24 h with chrysin (5 μ M) and AlCl₃ (50 μ M). At the end of incubation, cells were collected and the cytostatic effect, in terms of the number of total cells, was detected by using trypan blue (1:10). In parallel, cells were loaded with PI (25 μ g/mL) for 5 min at room temperature. The necrosis was detected by using an inverted fluorescence microscope (Eclipse Ti-E, Nikon Instruments Spa, Florence, Italy). The total cells were counted in a bright field, then only the red necrotic cells were counted using TRITC filters (EX 535/50, BS 575, EM 590LP). Data are expressed as a percentage of necrotic cells versus total cells.

2.3 In vivo tests

2.3.1 Animals

Experiments were conducted using male Swiss mice (25 – 30 g) about two months old. Animals were maintained at a stable temperature of 22 ± 2 °C and a controlled 12 hours light/dark cycle, with free access to food and water. All manipulations were carried out between 08:00 and 16:00. All the protocols and experimentations were approved by the Brazilian College of Animal Experimentation (COBEA) and were approved by the local Ethics in Research Committee (protocol number: 056/2016) of the Federal University of Goiás (UFG).

2.3.2 Experimental design

The animals were randomized into five groups (n = 14 – 16): control; aluminum chloride 100 mg/kg (AlCl₃) dissolved in water; chrysin 10 mg/kg (Chrysin 10); chrysin 30 mg/kg (Chrysin 30) and chrysin 100 mg/kg (Chrysin 100). The control group received water, while all other groups received AlCl₃ 100 mg/kg/day for 90 days (Treatment 1). On the 46th day, the control and AlCl₃ groups received normal saline (adjusted pH 7.4) while all the other groups received chrysin until the 90th day (Treatment 2). All treatments were administered daily by gavage at a volume of 10 µL/1 g.

The chrysin doses were chosen based on a previous work of He et al., 2012 and Sarkaki et al., 2019. The Al dose and treatment periods were chosen based on previous work of our group (Oliveira et al., 2018; Thomaz et al., 2018).

At the end of the behavioral tests, the number of animals per group was subdivided for the biochemical assays (n = 8) and the histopathological and morphometric analysis (n = 5).

2.4 Behavioral tests

2.4.1 Open field test (OFT)

Exploratory activity was measured in the OFT (Montgomery, 1956) at protocol day 90, previously to the memory task. The floor of the open field was divided into nine squares. Each animal was placed individually in the center of the arena, and the number of segments crossed (four-paw criterion) was recorded in a 5 min session.

2.4.2 Chimney test (CT)

Locomotor activity was measured in the CT (Boissier, 1960) also at protocol day 90. This test consisted of evaluating the ability of animals to climb back up through an acrylic tube. The animals were introduced in the tube horizontally, and when they reach the opposite

1 extremity, the tube was put in the vertical position, and the activity of the animals to climb for
2 30 sec was observed.
3
4
5
6

7 **2.4.3 Step-down avoidance test (SDPAT)**

8
9 The SDPAT has been used to study nonspatial long-term memory (Kameyama et al.,
10 11 1986). The apparatus consisted of a single box where the floor was made of a metal grid
12 13 connected to a shock scrambler. A safe platform was also placed in the box. The training
14 15 session (acquisition) day 91, consisted in putting the mice gently on the platform and upon
16 17 stepping with four paws onto the grid floor, an electric shock of 0.5 mA/s was delivered. The
18 19 latency of the step-down motion into the grid was recorded in the training session. Some
20 21 seconds later (~5), the mouse was removed from the SDPAT apparatus and returned to its home
22 23 cage. The retention trial was performed 24 h after training on day 92. For this, mice were placed
24 25 on the platform, but no shock was given when they went down. The criterion for learning was
26 27 taken as an increase in the transfer latency time on the retention trial as compared to the
28 29 acquisition trial. Therefore, short transfer latencies indicate poor retention. The box was
30 31 illuminated throughout the experimental period.
32
33
34
35
36
37
38
39
40

41 **2.5 Ex vivo tests**

42 **2.5.1 Tissue collection and preparation**

43
44 Twenty-four hours after the last behavioral test, the animals were anesthetized
45 46 intraperitoneally with ketamine and xylazine hydrochloride. They were subsequently sacrificed
47 48 by decapitation and the brain cortex and hippocampus were removed and dissected. Cerebral
49 50 tissue samples were homogenized in 0.1 mol/L potassium phosphate buffer (KPB), pH = 7.4
51 52 in a 1:10 (w/v) ratio. The homogenate was then centrifuged at 8000 x g for 10 min to yield the
53 54 low-speed supernatant (S1) fractions that were used in the assays.

58
59
60
61
62
63
64
65

2.6 Biochemical assays

2.6.1 Cholinesterase (ChEs) activity

Enzyme activities were carried out according to the method of Ellman et al., 1961. The S1 fractions were incubated with 0.3 mmol/L DTNB, and the enzymatic reaction was initiated by the addition of 0.45 mmol/L of ATCh and BTCh as the substrate for AChE and BChE, respectively. Enzyme activities were spectrophotometrically measured at 412 nm for 3 min. Results are expressed in $\mu\text{mol ACTh}/\text{min}/\text{mg}$ protein and $\mu\text{mol BCTh}/\text{min}/\text{mg}$ protein for AChE and BChE, respectively.

2.6.2 Lipid peroxidation (LPO) levels

For LPO measurement the method of thiobarbituric acid reactive substances (TBARS) was used. The TBARS estimation was spectrophotometrically performed following the method described by Ohkawa et al., 1979, with some modifications. The S1 fractions were incubated with thiobarbituric acid, acetic acid (pH 3.4), and SDS at 95 °C for 60 min. The reaction product was determined at 532 nm. For the interpretation of the results, a MDA curve was performed and the data are expressed as equivalents of MDA in nmol/mg protein.

2.6.3 Carbonylated protein (CP) levels

Protein carbonyl derivatives were measured following the method described by Levine et al., 1990, with some modifications. The S1 fractions were incubated with DNPH prepared in 2 mol/L HCl. The mixture was kept in the dark for 1 h and vortexed each 15 min. Denaturation buffer, ethanol, and hexane were then added to each tube and the final mixture was vortexed for 40 sec and centrifuged at 3000 x g for 10 min. The supernatant obtained was discarded. The pellet was washed with ethanol-ethyl acetate (1:1 v/v) and re-suspended in a

1 denaturation buffer. The sample was vortexed for 5 min and was used to measure absorbance
2 at 370 nm. Results are expressed as nmol of carbonyl content/mg protein.
3
4
5
6

7 **2.6.4 Superoxide dismutase (SOD) activity**

8
9 The brain cortex and hippocampus SOD activities were spectrophotometrically
10 determined according to the method of Misra and Fridovich, 1972. The principle of this method
11 is the ability of the superoxide dismutase enzyme to inhibit the autoxidation of epinephrine.
12 The S1 fractions were incubated with 60 mmol/L of epinephrine bitartrate (pH 10) and the
13 sample color intensity was measured at 480 nm. The enzymatic activity was expressed in units
14 (U) of SOD/mg of protein.
15
16
17
18
19
20
21
22
23
24
25

26 **2.6.5 Catalase (CAT) activity**

27
28 The brain cortex and hippocampus CAT activities were spectrophotometrically
29 determined by the H₂O₂ decomposition at 240 nm according to the method described by Aebi,
30 1984, with some modifications. The S1 fractions were incubated with 86 mmol/L H₂O₂ and
31 sodium phosphate buffer (pH 7.0). The enzymatic activity was expressed in U of CAT/mg of
32 protein. One U of enzyme thus decomposed one μ mol of H₂O₂/min at pH 7.0 at 25 °C.

4 Sections were stained by thionine acetate and analyzed in a Zeiss Axioscope A1 light
5
6 microscope (Zeiss, Germany). Morphometric analysis was performed to quantify the
7
8 neurodegeneration in terms of the percentage (%) of eosinophilic neurons (necrosis-like cells)
9
10 in the brain cortex and hippocampus (CA1 area). For this, 30 photomicrographic fields were
11
12 obtained (6 fields/animal, $n = 5$ animals/group). The percentage (%) of necrotic neurons was
13
14 obtained to the total number of neurons per photomicrographic field. All analyses were
15
16 conducted using Image Pro-Plus program version 6.1 (Media Cybernetics Inc., Silver Spring,
17
18 MD, USA).

46 **3. Results**

47 **3.1 In vitro studies**

48 **3.1.1 Neurotoxicity**

49
50
51 The cytotoxicity of chrysin was evaluated in neuronal SH-SY5Y cells to define the
52
53 range of concentrations not associated with toxicity. After 24 h of treatment with various
54
55 concentrations of chrysin (1.25 – 40 μM), the neuronal viability was measured using MTT
56
57
58
59
60
61
62
63
64
65

1 assay. As reported in Fig. 2A, the treatment with concentrations up to 5 μM did not affect
2 neuronal viability. Therefore, we selected the range of 1.25 – 5 μM for the following
3 experiments.
4
5
6

7 8 9 **3.1.2 Antioxidant activity in neuronal SH-SY5Y and microglial THP-1 cells**

10
11
12 The antioxidant activity of chrysin was first evaluated in neuronal SH-SY5Y cells
13 against the ROS formation induced by H_2O_2 . After 30 min of treatment with chrysin (1.25 – 5
14 μM) and H_2O_2 (100 μM), the ROS formation was detected using the fluorescent probe H_2DCF -
15 DA. As reported in Fig. 2B, chrysin significantly reduced the ROS formation in neuronal SH-
16 SY5Y cells with all the concentrations used ($p = 0.0001$). The antioxidant activity was dose-
17 correlated with EC_{50} (concentration in which the 50% of ROS formation is reduced) 4 μM and
18 maximum activity at 5 μM (51% of ROS formation inhibition). The antioxidant activity of
19 chrysin was then evaluated in both neuronal SH-SY5Y and microglial THP-1 cells against the
20 ROS formation induced by *t*-BuOOH, which is known to generate ROS from lipid peroxidation
21 (Christine et al., 2018). After 30 min of treatment with chrysin (1.25 – 5 μM) and *t*-BuOOH
22 (100 μM), the ROS formation was detected using the fluorescent probe H_2DCF -DA. As
23 reported in Fig. 3A, chrysin significantly decreased the ROS formation in neuronal SH-SY5Y
24 cells with all the concentrations used ($p = 0.0011$). The antioxidant activity was dose-correlated
25 with EC_{50} 2 μM and maximum activity at 5 μM (73% of ROS formation inhibition). To better
26 evaluate the ability of chrysin to exert its antioxidant activity at the neuronal membrane level,
27 we measured the TAA of cytosolic and membrane-enriched fractions of neuronal SH-SY5Y
28 cells treated with 5 μM of chrysin for 2 h. The membrane fractions, but not the cytosolic
29 fractions, obtained from SH-SY5Y cells treated with chrysin showed a significant increase in
30 TAA in comparison to untreated cells (untreated cells = $44.57 \pm 0.3526 \mu\text{molTE/mg prot}$ vs
31 cells treated with chrysin = $68.90 \pm 1.238 \mu\text{molTE/mg prot}$; $p = 0.0001$).

1 The antioxidant activity of chrysin was also evaluated in microglial THP-1 cells in the
2 same experimental conditions. As reported in Fig. 3B, Only the concentration of 5 μ M
3 significantly decreased the ROS formation induced by *t*-BuOOH in microglial THP-1 cells
4 (36% of ROS inhibition) ($p = 0.0011$). Driven by these results, the concentration of 5 μ M was
5 selected for the following experiments.
6
7
8
9
10

11 **3.1.3 Antioxidant and inflammatory activity in microglial THP-1 cells**

12
13
14
15
16 After 24 h of treatment with chrysin (5 μ M) and LPS (1 μ g/ml), the ROS formation was
17 detected using the fluorescent probe H₂DCF-DA. As reported in Fig. 4A, chrysin significantly
18 reduced the ROS formation evoked by 24 h of treatment with LPS ($p = 0.0020$). In parallel, the
19 expressions of pro-inflammatory cytokines iNOS, IL-1 β , and TNF α were evaluated in
20 microglial THP-1 cells after 24 h of treatment with chrysin and LPS by RT-PCR. As reported
21 in Fig. 4B-D, chrysin significantly decreased iNOS, IL-1 β , and TNF α expression at the
22 transcriptional level, suggesting its strong anti-inflammatory activity ($p = 0.0001$).

33 **3.1.4 Antioxidant activity against Fenton reaction/AlCl₃ in neuronal SH-SY5Y cells**

34
35
36
37 The antioxidant activity of chrysin was also evaluated against the pro-oxidant activity
38 of AlCl₃ on Fenton reaction in neuronal SH-SY5Y cells using the fluorescent probe H₂DCF-
39 DA. As shown in Fig. 5, the adding of AlCl₃ (50 μ M) to FeSO₄/H₂O₂ (50 μ M/200 μ M) reaction
40 for 15 min further increased the ROS formation in SH-SY5Y cells. In these experimental
41 conditions, chrysin (5 μ M) significantly abolished the pro-oxidant activity evoked by AlCl₃ (p
42 = 0.0001). In parallel, chrysin and AlCl₃ alone did not modify the basal level of ROS supporting
43 the ability of chrysin to counteract specific ROS generated by catalytic effects of AlCl₃ on
44 Fenton reaction.

To determine the neuroprotective effects of chrysin in neuronal SH-SY5Y cells, the cytotoxicity induced by AlCl₃ in terms of cytostatic effect and necrosis was measured using trypan blue and PI, respectively. As reported in Fig. 6A, chrysin (5 μM) significantly counteracted the cytostatic effect induced by 24 h of treatment with AlCl₃ in terms of the number of total cells (p = 0.0041). In the same experimental conditions, chrysin significantly reduced the necrosis induced by AlCl₃ (Fig. 6B-C) (p = 0.0007).

3.2 *In vivo* studies

3.2.1 Behavioral test

3.2.1.1 OFT and CT

Mice performances in the OFT and CT are presented in Table 2. No effects on spontaneous locomotor (p = 0.9662) or exploratory (p = 0.9518) activities were observed due to any of the treatments.

3.2.1.2 SDPAT

Mice performance in the SDPAT is presented in Fig. 7. No difference among groups was observed in the transfer latency time in the acquisition phase. Statistical analysis yielded a significant difference among the groups (p = 0.001) in the retention phase. Post-hoc comparisons revealed that the AlCl₃ group presented a lower transfer latency time (~87%) than the control group. Chrysin treatment at all tested doses (10, 30 and 100 mg/kg) prevented this impairment (p = 0.031, p = 0.037 and p = 0.032, respectively). All doses tested were not different when comparing the three chrysin doses (10, 30, and 100 mg/kg) between them (p > 0.05).

3.2.2 Biochemical assays

3.2.2.1 ChEs activity

1 The brain cortex and hippocampus AChE activities are presented in Fig. 8A. Statistical
2 analysis of the brain cortex AChE activity showed no significant difference among the groups
3
4 (p = 0.8028). Statistical analysis of the hippocampus AChE activity showed a significant
5 difference among the groups (p = 0.001). Post-hoc comparisons revealed that AlCl₃ increased
6 (~38%) the brain cortex AChE activity when compared to the Control group. All doses of
7 chrysin showed a similar significant ability to normalize the AChE activity.
8
9

10
11
12 The brain cortex and hippocampus BChE activities are presented in Fig. 8B. Statistical
13 analysis of the brain cortex BChE activity showed no significant difference among the groups
14 (p = 0.1166). Statistical analysis of the hippocampus BChE activity showed a significant
15 difference among the groups (p = 0.001). Post-hoc comparisons revealed that AlCl₃ increased
16 (~31%) the brain cortex AChE activity when compared to the control group. All doses of
17 chrysin showed a similar significant ability to normalize the BChE activity.

7 **3.2.3 Histopathology and morphometric analysis**

8
9 Histopathological analysis showed that AlCl₃ exposure induced tissue damage to the
10 cerebral cortex and the hippocampus, causing an increased incidence of degenerating neurons.
11
12 All groups exposed to AlCl₃ showed some neurons with nuclear disintegration and atrophic
13 cytoplasm. These neurons stained intensely in pink using the hematoxylin method (data not
14 shown), or in dark purple using the thionine acetate method, a pattern that is compatible with
15 eosinophilic neuronal death. As reported in Fig. 10A, morphologically, all chrysin treatments
16 decreased the occurrence of degenerative neurons with necrosis phenotype. The frequency (%)
17 of the necrotic cell in the brain cortex and CA1 hippocampus are presented in Fig. 10B.
18
19 Quantitative analysis of the brain cortex indicated that treatment with chrysin caused a
20 significant reduction in the frequency of necrotic neurons, especially in the chrysin 100 group.
21
22 Similar results were observed in the CA1 hippocampus, where all groups treated with chrysin
23 had a lower frequency of necrotic neurons when compared to the AlCl₃ group, being the most
24 significant reduction found in the chrysin 100 group.

44 **4. Discussion**

45
46 In this study, we showed the ability of chrysin to counteract the early oxidative stress
47 evoked by different oxidant treatments, including H₂O₂, *t*-BuOOH, and Fenton reaction in
48 presence of AlCl₃ as well as the late neurotoxicity triggered by AlCl₃ in neuronal SH-SY5Y
49 cells. Regarding the antioxidant activity of chrysin, several studies show that the presence of
50 two hydroxyl groups in the chrysin molecule is an important factor determining its antioxidant
51 potency against the oxidation at a cellular level (Huang et al., 2012). Dynamic distribution of
52

65

1 chrysin at a cellular level can contribute to antioxidant effects recorded in neuronal SH-SY5Y
2 cells. A recent *in vitro* study reported a quick uptake or metabolic degradation of chrysin by
3 human hepatocytes after 2 h of incubation in a culture system (Huang et al., 2012).
4 Interestingly, we demonstrated in similar experimental conditions the scavenger activity of
5 chrysin against the ABTS⁺ radical at membrane levels in neuronal SH-SY5Y cells, suggesting
6 the dynamic distribution of chrysin in the membrane. It was reported the membrane localization
7 and distribution of various flavonoids, including chrysin, can improve the antioxidant activity
8 in proximity to the double bonds of the cell membrane lipids (Günther et al., 2015). These
9 pieces of evidence may underlie the ability of chrysin to reduce the ROS formation elicited by
10 *t*-BuOOH in both neuronal SH-SY5Y and microglial THP-1 cells. Since *t*-BuOOH is an
11 oxidant compound that mimics the LPO in neuronal tissues, these results also suggest the
12 ability of chrysin to counteract the LPO at the neuronal and microglial membrane levels.

29 The antioxidant activity of chrysin at the membrane level could also modulate the redox
30 signaling in microglial cells. It is noted that NADPH oxidases present in the microglial
31 membrane are a source of ROS, such as H₂O₂ and O₂^{·-}, involved in pro-inflammatory
32 microglial activation (Haslund-Vinding et al., 2017). In this regard, we demonstrated that
33 chrysin reduced both the ROS formation and activation of pro-inflammatory gene expression,
34 such as iNOS, IL-1 β , and TNF α , stimulated by LPS in microglial THP-1 cells, suggesting its
35 potential ability to modulate the redox signaling at the membrane level. These findings
36 corroborate with the ability of chrysin to counteract the oxidative stress-driven
37 neuroinflammation in various experimental models of focal cerebral ischemia/reperfusion
38 injury, Parkinson's disease and isoniazid-induced neurotoxicity (Yao et al., 2014; Goes et al.,
39 2018; Çelik et al., 2020). However, we cannot exclude that chrysin exerts anti-inflammatory
40 effects through other molecular mechanisms such as the inhibition of nuclear factor-kappa B,
41 which is a signaling molecule involved in neuroinflammation (Ha et al., 2010; Li et al., 2019).

In this regard, further studies are needed to elucidate the anti-inflammatory mechanisms of chrysin.

Lastly, we demonstrated for the first time the antioxidant activity of chrysin against the pro-oxidant ability of Al in neuronal SH-SY5Y cells. The oxidative damage of Al observed in various *in vitro* and *in vivo* studies is a feature not expected for a metal without a redox capability (Singla and Dhawan, 2013). Several studies suggest that the increase of $O_2^{\cdot-}$ - lifetime mediated by Al - $O_2^{\cdot-}$ - complex coupled to Fenton reaction gives oxidative stress in biological environments (Singla and Dhawan, 2013). In this context, a recent study demonstrated that chrysin has a good scavenging ability for $O_2^{\cdot-}$. This is due to the nucleophilic reaction taking place between the unsaturated carbonyl group of chrysin and $O_2^{\cdot-}$ - as well as the single-electron transfer between the phenolic hydroxyl group and $O_2^{\cdot-}$ (Zheng et al., 2005). We can therefore assume that chrysin breaks the pro-oxidant activity of Al through its ability to neutralize the $O_2^{\cdot-}$ - downstream of the oxidative process triggered by Al.

The cell membrane is an important biological target of Al^{3+} , and the damage caused to membrane components may impair important functions. In particular, Al^{3+} ions altered the lipid profile and fluidity of the neuronal membrane, leading to a loss of membrane integrity (Singla and Dhawan, 2013). According to these evidence, we recorded the membrane integrity loss in terms of necrosis in neuronal SH-SY5Y cells treated with $AlCl_3$ for 24 h. Remarkably, chrysin also counteracted the necrosis induced by $AlCl_3$ in neuronal SH-SY5Y cells suggesting its ability to preserve the neuronal membrane integrity.

Taken together, *in vitro* results suggest that antioxidant and neuroprotective effects of chrysin against the toxicity of $AlCl_3$ share the same neuronal membrane target. The chrysin may act as a membrane shield against early oxidative events that contribute to progressive neurodegeneration and neuronal death triggered by $AlCl_3$ exposure.

Considering the limitations of the *in vitro* models to predict the *in vivo* response, the ability of chrysin to counteract the oxidative stress and neuronal death induced by Al was further evaluated in a mouse model of neurotoxicity induced by chronic exposure of ninety days to AlCl₃. Taken together, the *in vivo* results indicate that daily oral chrysin administration during forty-five consecutive days prevented non-spatial learning and memory impairment elicited by AlCl₃. In addition, the chrysin supplementation also normalized the increased activities of AChE and BChE, decreased the oxidative damage, in terms of LPO and protein carbonylation, as well as cell necrosis in the brain cortex and hippocampus.

It is well-known that in neurodegenerative disorders the CNS sensory and motor regions damage can be present (Albers et al., 2015). This kind of impairment can induce false results when behavioral memory tests are assessed. We, therefore, evaluated the motor activity of animals. The OFT and CT performance showed that AlCl₃ treatment did not affect their motor activity and interference in behavioral tests as well as the SDPAT acquisition phase. However, AlCl₃ affected the non-spatial long-term memory as recorded by the latency time decrease in the step down during the retention phase. This cognitive impairment in long-term memory was then recovered by chrysin treatment. In this context, AlCl₃ increased the AChE activity in the hippocampus, but not in the brain cortex, interfering with the processes of memory consolidation as observed in SDPAT. These findings suggest that the impairment of AChE activity in hippocampus structure elicited by AlCl₃ is enough to establish a cognitive deficit. A similar ChE activity pattern in the brain cortex and hippocampus after the different treatments were also recorded for BChE.

Several pre-clinical studies recorded flavonoid-inhibitor effects on ChEs activity indicating their potential use for the treatment of motor neuron and dementia disorders, such as myasthenia gravis, Lewy body dementia, and Alzheimer's disease (Khan et al., 2018). Among the plant-derived flavonoids, chrysin showed the ability to inhibit electric eels' AChE

1 activity as well as human AChE and BChE in *in vitro* systems (Balkis et al., 2015; Taslimi et
2 al., 2017).
3

4 It is established that Al promotes ROS and LPO in different tissues, including the brain
5 (Samarghandian et al., 2019). As expected, the AlCl₃ chronic administration to mice induced a
6 significant LPO, in terms of TBARS levels, in the brain cortex and hippocampus. Remarkably,
7 the chrysin treatment decreased the LPO elicited by AlCl₃ in both brain regions confirming its
8 ability to protect the tissue membrane from oxidative damage. These *in vivo* results corroborate
9 with the *in vitro* antioxidant profile of chrysin recorded in neuronal SH-SY5Y cells.

12
13
14
15
16
17
18

19 Along with the LPO elevation, the ROS formation also causes protein oxidation with
20 the formation of various carbonyl species. In this regard, AlCl₃ chronic exposure increased the
21 CP levels in the brain cortex and hippocampus, indicating that the pro-oxidant action of Al
22 targets both the polyunsaturated fatty acids and proteins. Remarkably, the chrysin treatment
23 decreased the CP levels suggesting the ability of this flavonoid to prevent the triggering of the
24 protein carbonylation process. It is noted that the protein carbonylation is non-enzymatic
25 leading to irreversible modifications in proteins (Ferdorova et al., 2014).

36 The role and effectiveness of the first-line defense antioxidants that include SOD, CAT,
37 and glutathione peroxidase (GPX) are important and indispensable in the entire defense
38 strategy of antioxidants, including flavonoids (Ighodaro and Akinloye, 2017). Under oxidative
39 stress conditions, SOD acts as a first-line defense against superoxide as it converts the O₂^{·-}
40 radical to H₂O₂ and molecular oxygen. Then CAT and the GPX, using reduced glutathione,
41 converts the H₂O₂ into H₂O (Maya et al., 2016). Considering that, Al can strengthen the
42 oxidative capacity of O₂^{·-}, directly or indirectly through catalysis of the Fenton reaction, we,
43 therefore, assessed the activity of SOD and CAT, two enzymes involved in the first extremely
44 efficient reactions of O₂^{·-} detoxification.

1 The conflicting effects promoted by Al on CAT and SOD activities in different rodent
2 brain regions has been described in the literature (Atienzar et al., 1998; Yuan et al., 2012;
3 Jelenković et al., 2014; Benyettou et al., 2017; Sadauskiene et al., 2020), highlighting critical
4 experimental conditions, such as Al concentration, treatment time, species and age of animals.
5
6 Our *in vivo* studies showed that the AlCl₃ treatment for 90 days inhibited CAT and SOD
7 activities in the hippocampus and increased the SOD activity in the cortex. The contradictory
8 increase of SOD can be interpreted as an adaptive neuronal response of the frontal cortex
9 involving a strong oxidative stress increase elicited by Al (Navarro et al., 2009). The different
10 composition of lipids between brain cortex and hippocampus and cortex could explain a greater
11 O₂^{·-} formation induced by Al and antioxidant response in terms of SOD levels in the
12 hippocampus. However, the chrysin treatment was able to reverse these enzymes activities
13 alterations, corroborating with the ability of chrysin to counteract early oxidant events at a brain
14 level.

31 Chronic oxidative damage induced by Al also leads to neuronal death, predominant in
32 necrosis (Feng et al., 2014; Yamawaki et al., 2019). The neuronal death in the brain cortex and
33 hippocampus can affect the learning and memory processes (Matthews, 2015; Yamawaki et
34 al., 2019). Our histological results in mice recorded that the treatment with AlCl₃ induces
35 significant neurodegeneration in the brain cortex and hippocampus. In particular, the
36 histological analysis showed focal and neurodegenerative changes along with the increased
37 number of degenerative neurons with necrosis phenotype. In this regard, the necrotic neuron
38 frequency in the brain cortex was higher than hippocampus suggesting that the cortex is the
39 most sensitive brain area to neuronal damage elicited by AlCl₃. Interestingly, a recent study
40 recorded that the Al content of different human brain tissues, including cortex, in AD, autism
41 spectrum disorder, and multiple sclerosis was significantly elevated suggesting a critical role
42 of this metal in the etiology of these neurodegenerative diseases (Exley and Mold, 2019). The

1 neurodegeneration in terms of necrosis was attenuated by chrysin in both the brain cortex and
2 hippocampus.
3

4
5 Taken together, *in vivo* results show that oral administration of chrysin can prevent and
6
7 counteract oxidative damage and neurodegeneration in the brain cortex and hippocampus
8
9 prompted by chronic exposure to AlCl₃. In particular, all the doses (10, 30, and 100 mg/kg) of
10
11 chrysin used showed significant antioxidant and neuroprotective effects in both brain regions.
12
13 However, the dose of 10 mg/kg chrysin already exhibited the maximum antioxidant and
14
15 neuroprotective activity at a brain level. This evidence suggests that the BBB crossing
16
17 processes could become saturated limiting the increase of the chrysin levels in the brain. After
18
19 oral administration, the chrysin is highly biotransformed in the liver, during which conjugated
20
21 metabolites chrysin-7-sulfate and chrysin-7-glucuronide are formed in mice (Mohos et al.,
22
23 2020). Despite these conjugates appear at higher concentrations in the circulation than chrysin,
24
25 they probably do not contribute to the cerebral effects because they cannot cross the BBB as
26
27 predicted by *in silico* studies (Daiana and Zoete, 2016; Daiana et al., 2016). These evidence,
28
29 therefore, support that chrysin is predominant in brain action. It is probably that rising the dose
30
31 of chrysin also increases its metabolites that limit the availability of chrysin in the circulation
32
33 to cross the BBB, explaining the same neuroprotective effects recorded between 10 and 100
34
35 mg/kg.

46 **5. Conclusion**

47
48 This study demonstrates the ability of chrysin by oral administration to protect critical
49
50 brain regions for cognitive function from oxidative damage and neurodegeneration induced by
51
52 chronic AlCl₃ exposure. Regarding the mechanisms of neuroprotective action, chrysin showed
53
54 the ability to act as a membrane shield against early oxidative events mediated by O₂^{·-} and
55
56 other ROS that contribute to neuronal death triggered by AlCl₃ exposure.

These findings support the potential use of chrysin as a food supplement for the prevention of neurological and neurodegenerative diseases or the maintenance of a healthy brain.

Conflict of interest

The authors disclose no actual or potential conflicts of interest, including financial, personal, or relationships with other people or organizations. All authors have contributed to the work and agreed with the presented findings.

Figure captions

Figure 1. Chemical structure of chrysin (IUPAC: 5,7-Dihydroxy-2-phenyl-4H-chromen-4-one, CAS registry number: 480-40-0).

Figure 2. Cytotoxicity and antioxidant activity of chrysin against H₂O₂-induced ROS formation in neuronal SH-SY5Y cells. **(A)** Cells were incubated for 24 h with various concentrations of chrysin (1.25 – 40 μM). At the end of incubation, the neuronal viability was measured using MTT assay. **(B)** Cells were incubated for 30 min with the fluorescent probe H₂DCF-DA. At the end of incubation, cells were treated with various concentrations of chrysin (1,25 – 5 μM) and H₂O₂ (100 μM). Data are represented as mean ± SEM of three independent experiments. Statistical analysis was performed using one-way ANOVA followed by Dunnett's test. ^ap = 0.0031, ^bp = 0.0001, and ^cp = 0.0001 when compared to cells treated with H₂O₂.

Figure 3. Antioxidant activity of chrysin against *t*-BuOOH-induced ROS formation in neuronal SH-SY5Y **(A)** and microglial THP-1 cells **(B)**. Cells were incubated for 30 min with the fluorescent probe H₂DCF-DA. At the end of incubation, cells were treated for 30 min with various concentrations of chrysin (1,25 – 5 μM) and *t*-BuOOH (100 μM). Data are represented as mean ± SEM of three independent experiments. Statistical analysis was performed using one-way ANOVA followed by Dunnett's test. **(A)** ^ap = 0.0335, ^bp = 0.0449, and ^cp = 0.0118 when compared to cells treated with *t*-BuOOH; **(B)** ^ap = 0.0035 when compared to cells treated with *t*-BuOOH.

Figure 4. Effects of chrysin against the oxidative stress and inflammation induced by LPS in microglial THP-1 cells. **(A)** Cells were incubated for 24 h with chrysin (5 μ M) and LPS (1 μ g/mL). At the end of incubation, ROS formation was measured using the fluorescent probe H₂DCF-DA. Data are represented as mean \pm SEM of three independent experiments. Statistical analysis was performed using Student's t-test. ^ap = 0.0020 when compared to cells treated with LPS. **(B-D)** Cells were incubated for 24 h with chrysin (5 μ M) and LPS (1 μ g/mL). At the end of incubation, iNOS **(B)**, IL-1 β **(C)** and TNF α **(D)** expression was measured by quantitative RT-PCR. Data are represented as mean \pm SEM of three independent experiments. Statistical analysis was performed using one-way ANOVA followed by Bonferroni's test. **(B)** ^ap = 0.0001 when compared to untreated cells and ^bp = 0.0154 when compared to cells treated with LPS; **(C)** ^ap = 0.0001 when compared to untreated cells and ^bp = 0.0122 when compared to cells treated with LPS; **(D)** ^ap = 0.0001 when compared to untreated cells and ^bp = 0.0038 when compared to cells treated with LPS.

Figure 5. Antioxidant activity of chrysin against the pro-oxidant effect of AlCl₃ on Fenton reaction in neuronal SH-SY5Y cells. Cells were incubated for 30 min with the fluorescent probe H₂DCF-DA. At the end of incubation, cells were first treated for 15 min with FeSO₄/H₂O₂/AlCl₃ (50 μ M, 200 μ M, and 50 μ M, respectively) and then treated for 15 min with chrysin (5 μ M). Data are represented as mean \pm SEM of three independent experiments. Statistical analysis was performed using one-way ANOVA followed by Bonferroni's test. ^ap = 0.0031 when compared to untreated cells, ^bp = 0.0022 when compared to cells treated with FeSO₄/H₂O₂ and ^cp = 0.0012 when compared to cells treated with FeSO₄/H₂O₂/AlCl₃.

μM). At the end of incubation, the cytotoxicity of AlCl_3 in terms of cytostatic effect (**A**) and necrosis (**B**) was assessed using trypan blue and propidium iodide, respectively. (**C**) Representative bright field (BF) and PI fluorescence images. Scale bars: 100 μM . Data are represented as mean \pm SEM of three independent experiments. Statistical analysis was performed using one-way ANOVA followed by Bonferroni's test. (**A**) ^a $p = 0.0033$ when compared to untreated cells and ^b $p = 0.0432$ when compared to cells treated with AlCl_3 ; (**B**) ^a $p = 0.0010$ when compared to untreated cells and ^b $p = 0.0071$ when compared to cells treated with AlCl_3 .

Figure 7. Effect of chrysin on AlCl_3 induced memory impairment in the step-down passive avoidance task. Data are represented as mean \pm SEM. for $n = 14$ to 16 animals per group. Statistical analysis was performed using one-way ANOVA followed by Tukey's test. ^a $p < 0.05$ when compared to the control group; ^b $p = 0.0310$ when compared to the AlCl_3 group. ^c $p = 0.0370$ when compared to the AlCl_3 group; ^d $p = 0.0320$ when compared to the AlCl_3 group.

Figure 8. Effect of chrysin on brain cortex and hippocampus AChE (**A**) and BChE (**B**) activities of mice treated with AlCl_3 . Data are represented as mean \pm SEM. for $n = 8$ animals per group. Statistical analysis was performed using one-way ANOVA followed by Tukey's test. (**A**) ^e $p = 0.0013$ when compared to the control group; ^f $p = 0.0118$, ^g $p = 0.0187$, and ^h $p = 0.0215$ when compared to the AlCl_3 group for hippocampus AChE activity; (**B**) ^e $p < 0.0002$ when compared to the control group; ^f $p = 0.111$, ^g $p = 0.0115$, and ^h $p = 0.0194$ when compared to the AlCl_3 group for hippocampus BChE activity.

Figure 9. Effect of chrysin on brain cortex and hippocampus LPO levels (**A**), CP levels (**B**), SOD activities (**C**) and CAT activities (**D**) of mice treated with AlCl_3 . Data are represented as

1 mean \pm SEM. for n = 8 animals per group. Statistical analysis was performed using one-way
2 ANOVA followed by Tukey's test. (A) ^a p = 0.0001 when compared to the control group, ^b p =
3 0.001, ^c p = 0.032, and ^d p = 0.010 when compared to the AlCl₃ group, for brain cortex MDA
4 levels; ^e p = 0.0005 when compared to the control group; ^f p = 0.0002, ^g p = 0.0001, and ^h p =
5 0.0001 when compared to the AlCl₃ group, for hippocampus MDA levels. (B) ^a p = 0.0001
6 when compared to the control group for brain cortex CP levels; ^e p = 0.0153 when compared
7 to the control group; ^f p = 0.001, ^g p = 0.027, and ^h p = 0.021 when compared to the AlCl₃
8 group, for hippocampus CP levels. (C) ^a p = 0.0001 when compared to the control group; ^b p =
9 0.0014, ^c p = 0.0385, and ^d p = 0.0395 when compared to the AlCl₃ group, for brain cortex
10 SOD activity; ^e p = 0.0015 when compared to the control group; ^f p = 0.0084, ^g p = 0.0001, and
11 ^h p = 0.0001 when compared to the AlCl₃ group, for hippocampus SOD activity. (D) ^e p =
12 0.0012 when compared to the control group; ^f p = 0.0064, ^g p = 0.0001, and ^h p = 0.0002 when
13 compared to the AlCl₃ group, for hippocampus CAT activity.

34 **Figure 10.** Histological sections of the frontal cerebral cortex (left column) and CA1 region of
35 the hippocampus (right column) (A). Thionine acetate staining method. Arrows indicate
36 degenerating neurons with necrosis appearance. These neurons stain intensely in dark purple
37 and show nuclear degeneration and atrophic cytoplasm. All chrysin treatments promoted a
38 marked reduction in degenerative neurons in both cerebral cortex and hippocampus. Frequency
39 of degenerative neurons in the brain cortex and hippocampus (B). Data are represented as mean
40 \pm SEM. for n = 5 animals per group. Statistical analysis was performed using one-way ANOVA
41 followed by Tukey's test. ^a p = 0.0001 when compared to the control group; ^b p = 0.0001, ^c p =
42 0.0001, and ^d p = 0.0001 when compared to the AlCl₃ group, for brain cortex necrotic cells
43 frequency. ^e p = 0.0041 when compared to the control group; ^f p = 0.0334, ^g p = 0.0387, and ^h
44 p = 0.0003 when compared to the AlCl₃ group, for hippocampus necrotic cells frequency.

Tables

Tables 1

Primer sequences for quantitative RT-PCR.

Primer	5' to 3' Sequence	
	Forward	Reverse
iNOS	TGAACTACGTCCTGTCCCCT	CTCTTCTCTTGGGTCTCCGC
IL-1 β	TGATGGCTTATTACAGTGGCAATG	GTAGTGGTGGTTCGGAGATTCG
TNF- α	ATCTTCTCGAACCCCGAGTG	GGGTTTGCTACAACATGGGC
B-actin	GCGAGAAGATGACCCAGATC	GGATAGCACAGCCTGGATAG
GAPDH	GGTCGGAGTCAACGGATTTG	GGAAGATGGTGGTGGGATTTC

Table 2

Spontaneous locomotor and exploratory activity in the open field and chimney test of mice

	Open Field (num)	Chimney (s)
	Crossings	Climbing
Control	102.0 \pm 5.30	13.92 \pm 2.08
AlCl ₃	110.8 \pm 11.51	15.70 \pm 3.05
Chrysin 10	109.6 \pm 19.21	16.16 \pm 1.69
Chrysin 30	115.4 \pm 23.35	16.44 \pm 2.08
Chrysin 100	107.8 \pm 12.97	15.14 \pm 2.25

Data are represented as mean \pm SEM for n = 14 -16 animals per group.
