**Summary**

Runs of homozygosity (ROH) are long stretches of DNA homozygous at each polymorphic position. The proportion of genome covered by ROH and their length are indicators of the level and origin of inbreeding. Frequent common ROH within the same population define ROH islands and indicate hotspot of selection. In this work, we investigated ROH in a total of 1131 pigs, from 20 European local pig breeds and in three cosmopolitan breeds, genotyped with the GGP Porcine HD Genomic Profiler. PLINK software was used to identify ROH. Size classes and genomic inbreeding parameters were evaluated. ROH Islands were defined by evaluating different thresholds of homozygous SNP frequency. A functional overview of breed-specific ROH islands was obtained via over-representation analyses of Gene Ontology biological processes. Mora Romagnola and Turopolje breeds had the largest proportion of genome covered with ROH (~1003 and ~955 Mb, respectively) whereas Nero Siciliano and Sarda breeds had the lowest proportion (~207 and 247 Mb, respectively). The highest proportion of long ROH (>16 Mb) was in Apulo-Calabrese, Mora Romagnola e Casertana. The largest number of ROH islands was identified in the Italian Landrace (n. 32), Cinta Senese (n. 26) and Lithuanian White Old Type (n. 22) breeds. Several ROH islands were in regions encompassing genes known to affect morphological traits. Comparative ROH structure analysis among breeds indicted similar genetic structure of local breeds across Europe. This study contributed to understand the genetic history of the investigated pig breeds and provided information to manage these pig genetic resources.

**Keywords:** Autozygosity; Population genomics; Selection signature; SNP; *Sus scrofa*

## 66 Introduction

67 Conservation programs of animal genetic resources, mainly constituted by numerous  
68 autochthonous breeds in all species, are usually challenged by their very small effective population  
69 size which, in turn, tends to increase inbreeding and to reduce genetic variability (Charlesworth &  
70 Willis 2009). Inbreeding depression is considered the result of the increased level of autozygosity.  
71 Pedigree information is traditionally used to calculate the inbreeding coefficient ( $F_{PED}$ ), defined as  
72 the probability that in a diploid individual, the maternal and the paternal derived alleles at a randomly  
73 selected locus are identical by descent (Wright 1922). This definition is equivalent to consider  $F_{PED}$   
74 as the proportion of autozygosity of an individual's genome. Then, the level of inbreeding of a  
75 population is expressed by averaging all  $F_{PED}$  individual values. Reliability of  $F_{PED}$  calculated in  
76 autochthonous breeds is in general lower than what is possible to obtain for animals in commercial  
77 selection nuclei. This is mainly due to incomplete registration and incorrect recording of all mating  
78 events derived by the extensive production systems in which local breeds are usually raised (Gomez-  
79 Raya *et al.* 2008; Kios *et al.* 2012). In addition, it is clear that a few assumptions used to calculate  
80 this pedigree-based coefficient are not correct and are used as approximations in the methods of  
81 calculations: i) all founder animals of the base population are expected to be unrelated, but this  
82 condition cannot be evaluated and it is usually not respected; ii) recombinant events occurring during  
83 meiosis mix equally the individual's paternal and maternal haploid genome copies, but this condition  
84 mimics only average events and not what actually happens in each specific meiosis; and iii) there is  
85 no selection biases on any parts of the genome, but this assumption is not respected considering that  
86 directional artificial selection or natural selection play important roles in shaping the genome of many  
87 domestic animal breeds.

88 Genome wide analyses, usually based on single nucleotide polymorphism (SNP) arrays, can be  
89 used to estimate the level of autozygosity of an animal genome by directly interrogating the genotype  
90 status at thousands of polymorphic sites (e.g. Kristensen *et al.* 2010). The proportion of the genome  
91 covered by runs of homozygosity (ROH) of a certain minimal length has been considered one of the

1  
2  
3 92 most precise estimation of the level of autozygosity, providing a measure of genomic inbreeding  
4  
5 93 ( $F_{ROH}$ ; Peripolli *et al.* 2017). Runs of homozygosity are defined as continuous chromosome stretches  
6  
7 94 in which all loci have a homozygous genotype (Gibson *et al.* 2006). Some ROH characteristics in a  
8  
9  
10 95 population (the average length of ROH, the average proportion of the genome covered by ROH and  
11  
12 96 the patterns of ROH distribution across the chromosomes) are considered indicators of the origin and  
13  
14 97 genetic history of a population (Ceballos *et al.* 2018). The high frequency of ROH in some  
15  
16  
17 98 chromosome regions identifies selection signatures derived from a reduced haplotype variability  
18  
19 99 around loci under natural or artificial selection (i.e. ROH island or ROH hotspots). By applying  
20  
21  
22 100 different strategies and methods, ROH islands have been used to detect signatures of selection in  
23  
24 101 several livestock species (Purfield *et al.* 2017; Bertolini *et al.* 2018; Grilz-Seger *et al.* 2018;  
25  
26 102 Mastrangelo *et al.* 2018; Peripolli *et al.* 2018), including the pig (Zhang *et al.* 2018; Gorssen *et al.*  
27  
28 103 2020; Schiavo *et al.* 2020b).

30  
31 104 A lot of different pig breeds have been developed through the combined action of artificial  
32  
33 105 directional selection and natural pressures that contributed to shape a large reservoir of genetic  
34  
35 106 diversity within the *Sus scrofa* species (Porter 1993). A large fraction of these genetic resources is  
36  
37  
38 107 however constituted by autochthonous breeds of small population size, usually well adapted to their  
39  
40 108 local agro-climatic and environmental conditions but less productive, compared to cosmopolitan  
41  
42 109 breeds or lines. Conservation programmes for these breeds, some of which considered unexplored  
43  
44  
45 110 genetic resources, have different levels of managing actions that range from advanced Herd Book  
46  
47 111 structures with specific breeding and selection plans to preliminary voluntary farmer-based herd  
48  
49 112 books or primitive conservation programmes (Čandek-Potokar & Nieto 2019). We recently analysed  
50  
51  
52 113 major and candidate gene markers in 20 autochthonous European pig breeds from several different  
53  
54 114 countries and obtained preliminary population structure results (Muñoz *et al.* 2018) that were refined  
55  
56 115 using SNP array information (Muñoz *et al.* 2019) and whole genome resequencing data (Bovo *et al.*  
57  
58 116 2020a, 2020b). Genome wide data indicated that average persistence and strength of linkage  
59  
60 117 disequilibrium between markers and SNP based effective population size varied among breeds

depending by the genetic structures and history of these breeds that experienced different genetic events (e.g. admixture, bottlenecks and genetic drift). Selection signatures were also obtained using  $F_{ST}$  statistics by analyzing SNP chip genotyping and sequencing data (Muñoz *et al.* 2019; Bovo *et al.* 2020a). Genomic inbreeding analyses in these breeds could add other information to refine their conservation programmes and identify appropriate strategies to control inbreeding level and infer other population structures or features.

In this study we analysed the same 20 European autochthonous pig breeds from nine different countries (Croatia, France, Germany, Italy, Lithuania, Portugal, Serbia, Slovenia and Spain) and other three cosmopolitan-derived breeds to obtain genomic inbreeding information from whole genotyping datasets by using ROH and other genomic approaches. We then evaluated the distribution of ROH in the genome of these breeds and identified putative selection hotspot regions that might be originated by different selection histories and structures of these pig genetic resources.

## Materials and methods

### *Animals*

Pigs included in this study were from 20 autochthonous breeds distributed in nine European countries (Alentejana and Bísara from Portugal; Iberian and Majorcan Black from Spain; Basque and Gascon from France; Apulo-Calabrese, Casertana, Cinta Senese, Mora Romagnola, Nero Siciliano and Sarda from Italy; Krškopolje from Slovenia; Black Slavonian and Turopolje from Croatia; Moravka and Swallow-Bellied Mangalitsa from Serbia; Schwäbisch-Hällisches Schwein from Germany; Lithuanian indigenous wattle and Lithuanian White old type from Lithuania) and three commercial breeds (Italian large White, Italian Landrace and Italian Duroc). Analysed pigs were selected by avoiding highly related animals (no full- or half-sibs). All animals had standard breed characteristics and were registered to their respective Herd Books. Table S1 reports detailed descriptions of the investigated breeds and selected animals (Čandek-Potokar & Nieto 2019). Pictures

1  
2  
3 143 of animals of the autochthonous breeds are reported in Muñoz *et al.* (2018, 2019) and Bovo *et al.*  
4  
5 144 (2020a).  
6  
7  
8 145

9  
10 146 ***Genotyping of single nucleotide polymorphisms***  
11

12 147 All pigs (39-55 for each breed; Table S2) were genotyped with the GeneSeek ® GGP Porcine  
13  
14 148 HD Genomic Profiler v1 (Illumina Inc, USA), which includes 68,516 SNPs evenly distributed with  
15  
16  
17 149 a median of 25 kb gap spacing. The average genotyping call rate was 0.94. Single nucleotide  
18  
19 150 polymorphisms were mapped on the Sscrofa11.1 genome version, following the procedure already  
20  
21  
22 151 described (Fontanesi *et al.* 2012, 2014). Only autosomal SNPs located in unique positions were  
23  
24 152 considered. Genotyping data were then filtered using PLINK software version 1.9 (Chang *et al.*  
25  
26 153 2015). Call rate of 0.90 and Hardy Weinberg equilibrium *P* of 0.001 were set as thresholds to keep  
27  
28  
29 154 SNPs. Although filtering for minor allele frequency (MAF) is necessary as best practice in most SNP  
30  
31 155 chip analyses, this approach excludes the SNPs that are homozygous for the whole breed, therefore  
32  
33 156 it could bring to an underestimation of the coverage in ROH (Meyermans *et al.* 2020). For this reason,  
34  
35 157 we analysed ROH without applying any MAF pruning. For comparison with other studies that applied  
36  
37  
38 158 a MAF threshold and to evaluate the impact of MAF on the calculated ROH parameters, we also used  
39  
40 159 a MAF threshold of 0.01 (indicated as method based on MAF > 0.01) and results are included in the  
41  
42 160 Supplementary material. All analyses in the text are derived without MAF pruning (indicated as  
43  
44  
45 161 method based on MAF ≥ 0.00), if not stated otherwise. Animals were discarded if their call rate was  
46  
47 162 <0.90. Table S2 reports the number of SNPs and animals considered for further analyses after  
48  
49 163 filtering.  
50  
51  
52 164

53  
54 165 ***Multidimensional-plot analysis of pig breeds and effective population size***  
55

56 166 The first three dimensions for a multidimensional (MDS)-plot have been obtained with PLINK  
57  
58 167 software version 1.9 and plotted with the R package “Scatterplot3d” (Ligges & Mächler 2003) to  
59  
60  
168 graphically visualize the genetic distances between the 23 pig breeds. Effective population size at

recent and remote generations was computed using SNP data with the software *SNeP* (Barbato *et al.* 2015) with default parameters, except for the maximum distance in bp between SNPs to be analysed, that has been set to 10 Mb, and the binwidth for the calculation of linkage disequilibrium that was set to 100 kb.

### ***Identification of runs of homozygosity***

Runs of homozygosity (ROH) were identified using PLINK software version 1.9 (Chang *et al.* 2015). No pruning was performed based on linkage disequilibrium to avoid biases that could be derived by this practice (Marras *et al.* 2015; Meyermans *et al.* 2020) but a minimum length of 1 Mb was set to detect ROH. This threshold may exclude short and common ROH determined by markers in linkage disequilibrium, as previously demonstrated (e.g. Ferencakovic *et al.* 2013; Marras *et al.* 2015). The following parameters, already used by Schiavo *et al.* (2020a), were considered to call ROH: i) the minimum number of consecutive homozygous SNPs included in the ROH was 15; ii) the minimum length that constituted the ROH was 1 Mb; iii) the number of heterozygous SNPs that were allowed in the ROH was 0; iv) the minimum density of SNP in a genome window was 1 SNP every 100 kb; v) the maximum gap between consecutive SNPs was 1000 kb. ROH were placed into five size classes (Kirin *et al.* 2010; Ferencaković *et al.* 2013a; Schiavo *et al.* 2020a): 1–2, 2–4, 4–8, 8–16 and >16 Mb, identified as ROH1–2 Mb, ROH2–4 Mb, ROH4–8 Mb, ROH8–16 Mb and ROH>16 Mb, respectively. The total number of ROH (nROH) was then obtained for each individual and for each length class. The average length of ROH ( $L_{ROH}$ , in Mb) and the sum of all ROH segments by animals ( $S_{ROH}$ , in Mb) were calculated. These parameters were also calculated for each breed by averaging individual data.

### ***Genomic inbreeding measures***

$F_{ROH}$  was calculated for each pig as the proportion of the autosomal genome covered by ROH.  $F_{ROH}$  was calculated using all the detected ROH with length >1 Mb ( $F_{ROH1}$ ) and also considering

1  
2  
3 195 higher thresholds of length, namely >4 Mb, >8 Mb, >16 Mb to obtain, respectively,  $F_{ROH4}$ ,  $F_{ROH8}$  and  
4  
5 196  $F_{ROH16}$  inbreeding coefficients. Averaged  $F_{ROH}$  values were calculated for each breed. In addition,  
6  
7  
8 197 chromosome (SSC)  $F_{ROH}$  ( $F_{ROHSSC}$ ) values were also estimated for each breed:  $F_{ROHSSC} =$   
9  
10 198  $L_{ROHSSC}/L_{SSC}$  (Silió *et al.* 2013), in which  $L_{ROHSSC}$  is the total length of an individual's ROH in each  
11  
12 199 SSC and  $L_{SSC}$  is the length of each chromosome covered by the involved SNPs.

14  
15 200 Other genomic inbreeding coefficients were calculated: i) the variance-standardized  
16  
17 201 relationship minus 1 ( $F_{hat1}$ ); ii) the excess of homozygosity-based inbreeding estimate ( $F_{hat2}$ ); iii) the  
18  
19 202 estimate based on correlation between uniting gametes ( $F_{hat3}$ ); iv) the values of the diagonal elements  
20  
21 203 of the genomic relationship matrix, GRM ( $F_{GRM}$ ; Van Raden *et al.* 2011); v) the difference between  
22  
23  
24 204 observed and expected number of homozygous genotypes ( $F_{HOM}$ ).  $F_{hat1}$ ,  $F_{hat2}$ ,  $F_{hat3}$  and  $F_{GRM}$ . GRM  
25  
26 205 coefficients were calculated using PLINK1.9 with the ported functions of GCTA software v. 1.92  
27  
28 206 (Yang *et al.* 2011).  $F_{HOM}$  was computed with PLINK software version 1.9 (Chang *et al.* 2015).  
29  
30  
31 207 Pearson correlation coefficients ( $r$ ) between all evaluated inbreeding coefficients were calculated.

32  
33 208  
34  
35 209 ***Identification of runs of homozygosity islands and annotation of genome regions***

36  
37 210 First, the proportion of SNPs residing within a ROH was calculated for a given breed by  
38  
39  
40 211 counting the amount of times a SNP appeared in a ROH within the given breed divided by the total  
41  
42 212 number of genotyped pigs of that breed. Then, to call ROH islands a threshold of frequency should  
43  
44  
45 213 be defined. A few methods have been proposed for this purpose, each with pros and cons (e.g. Purfield  
46  
47 214 *et al.* 2017; Grilz-Seger *et al.* 2018, Gorssen *et al.* 2020). However, there is no general agreement on  
48  
49 215 their use in different contexts and populations. In this study, we used three methods to identify ROH  
50  
51 216 islands that differed on the threshold that was applied.

52  
53 217 One method already reported in other studies (Grilz-Seger *et al.* 2018, 2019a, 2019b) uses an  
54  
55  
56 218 empirical threshold defined as the percentage of animals (usually 50%), whitening a population, positive  
57  
58 219 for a ROH at each tested SNP (hereinafter called 50% of animals-based threshold). When the level  
59  
60 220 of inbreeding is high, the identification of islands due to signature of selection based on a fixed

percentage of animals having ROH at each position of the genome might increase the number of false positive ROH islands that indicate the presence of signature of selection. This method could increase the risk of type II errors when the level of inbreeding in the population is low. Another method, frequently applied for this aim (e.g. Szymatola *et al.* 2016; Purfield *et al.* 2017; Bertolini *et al.* 2018; Mastrangelo *et al.* 2018; Zhang *et al.* 2018), defines a percentile threshold (99th percentile) based on the top 1% of SNPs observed in a ROH in each breed (hereinafter called percentile-based threshold). Adjacent SNPs over this threshold are then merged into genomic regions corresponding to ROH hotspots. This method identifies always ROH islands as the threshold is defined on a percentile within the breed dataset and does not consider the structure of the population or its level of inbreeding.

Considering the problems that these two methods could have, we developed a third method where the identification of the threshold was chosen using a linear model in which the number of animals having SNPs in a ROH was a function of the average  $S_{ROH}$  level of the breed, which approximate the genomic inbreeding level of a population (hereinafter called  $S_{ROH}$  based-threshold). ROH islands were then considered in the text and annotated based on the results derived by this latter method. Results obtained with the other two methods were used for a comparative analysis. ROH co-occurrence between different breeds were investigated by comparing the average homozygosity level in each breed at each island region. For this evaluation, each ROH island identified in at least one breed was considered.

Similarity among breeds was investigated by computing a first matrix  $\mathbf{A}$  ( $n$  breeds  $\times$   $m$  ROH islands regions identified across all the analyzed breeds) whose generic entry  $a$  is the average breed-specific frequency value of a given ROH island computed as follows:  $a = \frac{\sum_i AF_i}{n}$ , where  $AF_i$  is the allele frequency of the  $i^{th}$  SNP belonging to the ROH island and including  $n$  SNPs. This matrix was used to compute a similarity matrix  $\mathbf{D}$  ( $n \times n$ ), whose generic entry  $d$  is the Euclidean distance between pairs of breeds with values scaled in the range 0 to 1. A final dissimilarity matrix (1-D) was obtained

1  
2  
3 245 and used to produce a heatmap in R (package *corrplot*; Wei and Simko, 2007) showing similarity  
4  
5 246 among breeds.

7  
8 247 Genes annotated in the Sscrofa11.1 pig genome version that mapped in the identified ROH  
9  
10 248 islands were retrieved using the Ensembl Biomart tool (<http://www.ensembl.org/biomart/martview/>)  
11  
12 249 and from NCBI Sscrofa11.1 GFF file. Functional enrichment analysis was carried out with *Enrichr*  
13  
14  
15 250 (Chen *et al.* 2013) via Fisher’s exact test. Analyses run over the Biological Process (BP) branch of  
16  
17 251 the Gene Ontology (GO) (Ashburner *et al.* 2000), by interrogating a total of 5103 functional terms  
18  
19 252 covering 14433 human genes. Breed-specific analyses were run by using as input set the list of genes  
20  
21  
22 253 included in ROH islands. We considered as statistically over-represented terms those having: i) at  
23  
24 254 least two input genes from two or more different ROH islands and ii) an adjusted *P* lower than 0.10.

28 256 **Results**

30  
31 257 ***Genomic relationships among breeds and effective population size***

32  
33 258 Genomic information on the analysed breeds based on SNP data was graphically presented in  
34  
35 259 a tri-dimensional MDS-plot (Figure S1). This plot showed that distinct groups of individuals were  
36  
37  
38 260 usually from the same breed. Several breeds were well separated from other groups. These distinct  
39  
40 261 groups included breeds from several countries: Gascon and Basque from France; Italian Large White,  
41  
42 262 Italian Duroc and Mora Romagnola from Italy; Iberian from Spain; Turopolje from Croatia. Most of  
43  
44  
45 263 the other breeds formed a continuous large cluster showing a general geographical distribution  
46  
47 264 gradient as already reported in principal component analyses that included the same autochthonous  
48  
49 265 breeds (Muñoz *et al.* 2019).

50  
51 266 Effective population size (*Ne*) estimated with software *SNeP* for the 23 breeds is reported in  
52  
53  
54 267 Table S3. For all 20 autochthonous breeds, results confirmed the general low *Ne* for most breeds as  
55  
56 268 already reported by Muñoz *et al.* (2019) who applied a similar estimation method. At 5 generations  
57  
58 269 ago, breeds with the lowest *Ne* values were Turopolje, Mora Romagnola, Apulo-Calabrese and  
59  
60  
270 Casertana (*Ne* = 15, 16, 22 and 22, respectively). These breeds had the lowest estimated *Ne* also in

the study of Muñoz *et al.* (2019) even if in different order. The autochthonous breeds with the largest  $N_e$  were Iberian, Nero Siciliano, Alentejana, Majorcan Black, Sarda and Bísara ( $N_e = 69, 68, 61, 58, 57$  and  $55$ , respectively). The commercial breeds had a higher  $N_e$  than all other remaining autochthonous breeds. In Italian Duroc, Italian Landrace and Italian Large White  $N_e$  at 5 generation ago was equal to  $53, 59$  and  $61$ , respectively.

### ***Runs of homozygosity in the investigated breeds***

Table 1 ( $MAF \geq 0.00$ ) and Table S4 ( $MAF > 0.01$ ) show the average size and average number of ROH (considering all  $ROH > 1$  Mb) per pig (average  $L_{ROH}$  and average  $n_{ROH}$ , respectively) and the average  $S_{ROH}$  values per animal in the 23 breeds. Minimum and maximum values for these three parameters are reported in Table S5. As expected, the parameters calculated without any MAF pruning were always higher than the parameters calculated using  $MAF > 0.01$ . The breeds that had the highest mean  $n_{ROH}$  were Basque, Italian Duroc and Turopolje (n. 107, n. 104 and n. 80, respectively) and the breeds with the lowest mean  $n_{ROH}$  were Nero Siciliano (n. 24) Sarda (n. 27) and Moravka (n. 30). The mean  $L_{ROH}$  in all autochthonous breeds was larger than that of all three commercial breeds. Three Italian local breeds (Mora Romagnola, Apulo-Calabrese, and Casertana) had the largest  $L_{ROH}$  (14.38, 14.21 and 12.63 Mb, respectively). Among the autochthonous breeds, the lowest  $L_{ROH}$  was observed in Alentejana (6.49 Mb), Iberian (6.50 Mb) and Majorcan Black (6.58 Mb). The maximum ROH length was observed in the largest chromosomes and reached 24.34 Mb in Mora Romagnola (SSC1), 23.36 Mb in Nero Siciliano (SSC1), 22.64 Mb in Moravka (SSC1) and 21.55 Mb in Apulo-Calabrese (SSC13). Mora Romagnola and Turopolje breeds had the largest mean  $S_{ROH}$  (a total of  $\sim 1003$  and  $\sim 955$  Mb, respectively) whereas Nero Siciliano and Sarda breeds had the lowest mean values for this parameter ( $\sim 207$  and  $\sim 247$  Mb, respectively). The maximum  $S_{ROH}$  value was observed in one Mora Romagnola and one Black Slavonian pig that had about half of their genome covered by ROH (Table S5).

1  
2  
3 296 Figure 1 shows the correlation plots between the  $S_{ROH}$  and the  $nROH$  values over the individual  
4  
5 297 pigs in the 23 breeds. Basque and Gascon showed very homogeneous plots, indicating that most pigs  
6  
7  
8 298 of these two breeds had very similar within individual ROH parameters ( $nROH$ ,  $L_{ROH}$  and  $S_{ROH}$ ). The  
9  
10 299 opposite was the heterogeneous distribution observed in the Apulo-Calabrese, Bísara, Casertana and  
11  
12 300 Turopolje breeds (Figure 1).

14  
15 301 Figure 2 reports the proportion of ROH of the five different length classes in each breed. Table  
16  
17 302 S6 lists the corresponding values. The highest proportion of long ROH ( $>16$  Mb) was in Apulo-  
18  
19 303 Calabrese, Mora Romagnola e Casertana (about 25%, 23% and 23%, respectively). Apulo-Calabrese,  
20  
21 304 Casertana, Mora Romagnola and Turopolje had the lowest proportion of short-medium ROH (ROH1-  
22  
23  
24 305 8). All three commercial breeds, Alentejana, Gascon, Iberian, Majorcan Black, Nero Siciliano,  
25  
26 306 Lithuanian indigenous wattle, Lithuanian White Old Type and Schwäbisch-Hällisches had more than  
27  
28 307 50% of short ROH (ROH1-2 and ROH2-4).

31 308  
32  
33 309 ***Genomic inbreeding parameters based on runs of homozygosity***

35 310 Table 2 reports the mean and standard deviation of genomic inbreeding parameters calculated  
36  
37 311 using ROH from different size classes in the 23 breeds. Mora Romagnola, Turopolje and Apulo  
38  
39 312 Calabrese and Casertana were the autochthonous breeds with the highest  $F_{ROH}$  values, considering all  
40  
41 313 ROH classes. For example, among these breeds  $F_{ROH1}$  ranged from 0.409 (Mora Romagnola) to 0.243  
42  
43 314 (Casertana). Among the commercial breeds, Italian Duroc had the highest  $F_{ROH}$  values. The lowest  
44  
45 315  $F_{ROH1}$  levels were observed in Nero Siciliano (0.085), Sarda (0.101) and Moravka (0.118).

48  
49 316 When considering only medium-long ROH to calculate other ROH based inbreeding  
50  
51 317 parameters (i.e.  $F_{ROH4}$ ,  $F_{ROH8}$  and  $F_{ROH16}$ ), the values decreased in all breeds, as expected. Among  
52  
53 318 those with high  $F_{ROH1}$ , this drop was more evident in the breeds that had a high percentage of short  
54  
55 319 ROH than in breeds that had many long ROH. For example, the Italian Duroc  $F_{ROH16}$  value was about  
56  
57 320 2.5 times lower than that of  $F_{ROH1}$  value whereas in Mora Romagnola, Turopolje, Apulo-Calabrese  
58  
59 321 and Casertana their  $F_{ROH16}$  values decreased only 1.4-1.6 times compared to their respective  $F_{ROH1}$

values. The distribution of the  $F_{ROH}$  values in the analysed breeds is shown in the boxplots of Figure 3.

The genome wide  $F_{ROH}$  information was also dissected by considering the average proportion of all ROH covering the different autosomes ( $F_{ROHSSC}$ ). Among all breeds, Mora Romagnola and Turopolje had the highest  $F_{ROHSSC}$  values for 10 (SSC1, SSC4, SSC8, SSC9, SSC10, SSC13, SSC14, SSC15, SSC16 and SSC17) and 5 (SSC2, SSC3, SSC5, SSC6 and SSC11) chromosomes, respectively. Apulo-Calabrese had the highest  $F_{ROHSSC}$  values for SSC7 and SSC18 whereas Basque had the highest  $F_{ROHSSC}$  value for SSC12 (Figure S2).

Mean  $F_{ROH1}$ ,  $F_{ROH4}$ ,  $F_{ROH8}$  and  $F_{ROH16}$  breed values were negatively correlated with the estimated breed  $N_e$  values at 5 generation ago, defined as reported above ( $r = -0.685$ ,  $-0.722$ ,  $-0.737$  and  $-0.716$ , respectively;  $P < 0.0001$ ).

### ***Other genomic inbreeding parameters and their correlations with $F_{ROH}$***

Other parameters that have been proposed as estimators of the level of genomic inbreeding were calculated in the 23 breeds (Table S8). The average  $F_{hat1}$  value was positive in only two breeds (Apulo-Calabrese and Sarda) and ranged from  $-0.320$  (Mora Romagnola) to  $0.010$  (Sarda), with large within breed variability (the largest standard deviation was in Turopolje) and among breeds variability. These considerations could be also applied for the  $F_{GRM}$  parameter which is equivalent to  $F_{hat1}$  (even if scaled in a different way). The average  $F_{hat2}$  and  $F_{hat3}$  parameters had both the extreme values for the same breeds (Lithuanian indigenous wattle with the lowest values and Apulo-Calabrese with the highest values) with similar within and among breed variability (Table S8). The average  $F_{HOM}$  values were negative in 11 out of 23 breeds and ranged from  $-0.070$  in Lithuanian Indigenous Wattle to  $0.124$  in Apulo-Calabrese. Turopolje had the largest standard deviation for this parameter ( $0.24$ ). Distribution plots of the  $F_{hat1}$ ,  $F_{hat2}$ ,  $F_{hat3}$  and  $F_{HOM}$  parameters in the analysed breeds are reported in Figure S3 and Figure S4.

Correlations between all  $F_{ROH}$  parameters and all other genomic inbreeding measures for each breed are reported in Table S9.  $F_{HOM}$  had always very high and consistent correlations with the ROH based measures over all breeds. For example, correlations with  $F_{ROH1}$  and  $F_{ROH4}$  ranged from 0.819 and 0.814 for the Nero Siciliano breed to 0.987 and 0.982 for the Bísara breed. Correlations between  $F_{hat2}$  and  $F_{ROH1}$  and  $F_{ROH4}$  had some lower values even if again very high and consistent across breeds (they ranged from 0.447 or 0.450 in Swallow-Bellied Mangalitsa to 0.909 and 0.906 in Casertana).  $F_{hat1}$  and  $F_{hat3}$  showed inconsistent correlations compared to those of the other measures, including also negative values (Table S9). All these other genomic inbreeding measures had low negative correlations with  $Ne$  (from -0.11 to -0.18).

**Run of homozygosity islands**

Table 3 summarizes the number of ROH islands and the fraction of the genome covered by ROH islands identified using the  $S_{ROH}$  based-threshold in the 23 pig breeds. Figure 4 includes the Manhattan plots of a few breeds with extreme numbers of ROH islands. Figure 5 reports the pairwise similarities between breeds when overlapping ROH islands across breeds were considered. Some common features across breeds were evident.

The largest number of ROH islands was identified in the Italian Landrace (n. 34), Cinta Senese (n. 26) and Lithuanian White Old Type (n. 22) breeds. The largest covered fraction of the genome was observed in the Italian Duroc (92.85 Mb), Turopolje (80.82 Mb, with the largest averaged size of ROH islands) and Italian Landrace (75.03 Mb). No ROH islands were observed in Apulo-Calabrese and in Sarda breeds.

Table S10 compares the results obtained using the  $S_{ROH}$  based-threshold method with the results obtained using the other two methods considered in this study (the 50% of animals-based threshold and the percentile-based threshold methods, see Materials and methods). The Manhattan plots for all breeds and including the thresholds derived by the three methods is reported in Figure S5. Breeds with the highest level of genomic inbreeding estimated using  $F_{ROH}$  measures, like Mora Romagnola,

Turopolje and Basque (Table 2), showed the highest number of ROH islands and the largest fraction of genome covered by ROH islands with the 50% of animals-based threshold method (n. 91 with 756 Mb in Mora Romagnola, n. 129 with 747 Mb in Turopolje and n. 93 in Basque with 312.9 Mb). Using the percentile-based threshold method, the number of ROH islands and the total length of the genome fractions covered by these regions were similar in all breeds and ranged from n. 7 (Mora Romagnola) to n. 20 (Italian Landrace ) and from 19.83 Mb (Casertana) to 44.51 Mb (Turopolje). These methods could capture different information from the analysed populations. It seems however, that these two latter methods are, to some extent, biased by the genetic structure of the analysed populations and by the methodologies that are applied.

The complete list of ROH islands identified in the investigated breeds, using the  $S_{ROH}$  based-threshold method, including the genes annotated in these regions, is reported in Table S11. Several breeds had ROH islands encompassing genes that are well known to affect exterior traits, that might contribute to differentiate these pig breeds. For example, Gascon and Turopolje had a ROH island on SSC6 which includes the *melanocortin 1 receptor (MC1R)* gene and Krškopolje and Turopolje had another ROH island on SSC8 which includes the *v-kit Hardy-Zuckerman 4 feline sarcoma viral oncogene homolog (KIT)* gene. These two genes are well known to affect coat colour and colour patterns (Fontanesi & Russo 2013). Two genes that are known to affect vertebral number (*nuclear receptor subfamily 6 group A member 1, NR6A1* on SSC1; and *vertnin, VRTN* on SSC7; Mikawa *et al.* 2007, 2011) were in two ROH islands observed in Italian Landrace and in Schwäbisch-Hällisches breeds, respectively. Moravka and Schwäbisch-Hällisches breeds had a ROH island on SSC5 including the *methionine sulfoxide reductase B3 (MSRB3)* gene whose variants have been associated with ear size in pigs (Chen *et al.* 2018; Bovo *et al.* 2020a). Cinta Senese and Italian Duroc had a ROH island including other genes that have been shown to affect body size (*caspase 10, CASP10*; and *non-SMC condensin I complex subunit G, NCAPG*; Rubin *et al.* 2012).

A functional overview of breed-specific ROH islands identified using the  $S_{ROH}$  based-threshold method was obtained via over-representation analyses of GO biological processes (Table S12). Few

1  
2  
3 399 terms characterizing ROH islands were detected in two breeds (Krškopolje and Swallow-Bellied  
4  
5 400 Mangalitsa) only. Terms were general and included pattern recognition receptor signaling pathway,  
6  
7  
8 401 toll-like receptor signaling pathway, zymogen activation, cellular response to radiation and negative  
9  
10 402 regulation of cell differentiation.  
11  
12 403

14  
15 404 **Discussion**

16  
17 405 The demographic history of a population can be inferred using information from the average  
18  
19 406 distribution, coverage, size and patterns of ROH that can be identified in the individuals belonging to  
20  
21  
22 407 the population using high density SNPs data (Ceballos *et al.* 2018). In this study we detected ROH in  
23  
24 408 the genome of pigs from 20 autochthonous and three commercial breeds and compared the obtained  
25  
26 409 ROH genome landscapes patterns. These breeds represent populations that derived from several  
27  
28  
29 410 countries and originated in different production systems that largely contributed to shape their genetic  
30  
31 411 structures.

32  
33 412 Combining different population genomic parameters calculated in this study it could be possible  
34  
35 413 to reconstruct, to some extent, the genetic events and history that contributed to define the current  
36  
37  
38 414 genetic pools of the investigated breeds. ROH based fingerprinting are left in the analysed breeds and  
39  
40 415 can be used to divide the 23 breeds in a few macro-groups that could have independently experienced  
41  
42 416 similar genetic trajectories.

43  
44  
45 417 The ROH complement of recently inbred populations is defined by a large number of ROH  
46  
47 418 with large size and a large fraction of the genome covered by ROH (high  $S_{ROH}$ ), owing to very recent  
48  
49 419 pedigree inbreeding loops, accompanied by a small  $N_e$ . The large  $S_{ROH}$  standard deviation indicates  
50  
51  
52 420 a low uniformity of the animals, that means that there might be different substructures or  
53  
54 421 heterogeneity in the population or that an original bottleneck or founder effect could have increased  
55  
56 422 the range of ROH size. Recent inbreeding features accompanied by a constituting bottleneck series  
57  
58  
59 423 of events can be clearly evidenced in a few Italian local breeds, i.e. Apulo-Calabrese, Casertana, Mora  
60  
424 Romagnola, and in Turopolje. The high level of inbreeding could have masked regions that harbor

selection of signatures as most of these breeds showed a low number of ROH islands (from zero to 7, considering the  $S_{ROH}$  based method; Table 3) apart Turopolje that seems to maintain a quite high level of ROH specific regions (n. 17; Table 3). These breeds need to be carefully managed to reduce or control the high level of inbreeding. Programmes in this direction are currently under way in the Italian breeds (ANAS, 2020).

Other breeds have a quite high  $S_{ROH}$  level but with short ROH indicating the occurrence of a past bottleneck and then a quite good isolation of the genetic pool. This is a case that can be observed in the two French breeds, Basque and Gascon, and in the Italian breed Cinta Senese. Differences in the three breeds are evident in the number of ROH islands that might indicate a low-medium level of specific signatures of selection in the French breeds (7 in the Basque that also had the largest number of nROH among the three - and 12 in the Gascon) and a high level of characterizing signatures in the Cinta Senese (26 ROH islands) probably due to different levels of selection pressures and adaptation of the three considered populations. A similar genetic history seems evident in the Italian Duroc breed (which however had a larger  $N_e$ ; Table S3), reflecting deeper parental relatedness and consistent with an original strong bottleneck that occurred at the beginning of the 1990' when the heavy pig selection programme was defined and differentiated the Italian Duroc breed from other Duroc lines (Bosi & Russo 2004).

Breeds that experienced recent admixtures had, in general, a low nROH and as a proportion, had a higher frequency of short-medium ROH than long ROH, with high  $N_e$ . This group included the two breeds that had nROH <30,  $S_{ROH}$  <300.00 Mb, and  $N_e$  >55, i.e. Nero Siciliano and Sarda for which the ROH derived landscape was in agreement with the large variability observed in candidate gene markers and SNP chip data (Muñoz *et al.* 2018, 2019). Other breeds (i.e. Alentejana, Black Slavonian, Krskopolje, Lithuanian indigenous wattle and Moravka) had similar ROH patterns with that described for these two Italian breeds even if not so extreme (nROH <40,  $S_{ROH}$  <350.00 Mb). They constitute a heterogeneous group of populations that might have experienced some moderate introgression over the period of their constitution or that these events occurred in the past and at

present they maintain a moderate level of variability. The low-medium number of ROH islands (from 3, Moravka, to 15 Krskopolje) indicates a low-medium level of differentiation in terms of specific ROH features. Another group of intermediate breeds (which some features partially overlapping with those of the previous group) with medium  $nROH$  and, in general, with a medium level of inbreeding ( $nROH > 40$  and  $S_{ROH} > 300$ ) includes Bísara, Lithuanian White Old Type, Majorcan Black, Schwäbisch-Hällisches and Swallow-Bellied Mangalitsa.

Three other breeds, i.e. Iberian, Italian Landrace and Italian Large White, had characteristic ROH derived feature of commercial breeds or large populations, as expected from their large population size (consistent with the large  $N_e$ ). The two Italian breeds had some indicators of more specific differentiations and signatures of selection with a higher number of  $nROH$ , lower  $N_e$  and larger fraction of the genome included in ROH islands than the Iberian breed. This fact could be also due to the high level of genetic diversity observed within the Iberian breed, sometime higher than in some European pig breeds (Fabuel *et al.* 2004). This is consistent with the structure of these three populations, with the two Italian breeds being derived by small selection nuclei specifically addressing a selection programme for heavy pigs. The presence of common features among breeds raised in different countries suggests that a few ROH islands might capture some adaptive features that are shared across populations and production systems.

The general picture depicted by the ROH profiles was able to summarize the main elements that characterize the population structure of the analysed breeds. For a few of them the potential burden derived by the ROH should be evaluated with attention. An increased homozygosity for (partially) recessive detrimental mutations maintained at low frequency in populations by mutation–selection balance has been suggested to be one of the main causes of inbreeding depression. Genomic inbreeding measures can help to manage all these pig populations.  $F_{ROH}$  based measures seems more appropriate than all other calculated parameters and are highly correlated with  $N_e$  indicating that they better reflect the population structure and then the effective inbreeding level of the animals, as we

1  
2  
3 476 already reported comparing these measures with pedigree based inbreeding estimations (Schiavo *et*  
4  
5 477 *al.* 2020a).

7  
8 478 The method that we considered to identify ROH islands considers the level of inbreeding of the  
9  
10 479 breeds to reduce the biases derived by the large fraction of the genome covered by ROH in highly  
11  
12 480 inbred populations and to increase the probability to capture signatures of selection able to explain  
13  
14 481 morphological or adaptative features that characterize the uniqueness of these genetic resources.  
15  
16  
17 482 Some of the ROH islands contained genes responsible for domestication signatures related to exterior  
18  
19 483 traits and morphological adaptation (i.e. coat colour genes: *MC1R* and *KIT*; Fontanesi & Russo 2013;  
20  
21  
22 484 vertebral number: *NR6A1* and *VRTN*, Mikawa *et al.* 2007, 2011; parts of the body and body size:  
23  
24 485 *CASP10*, *MSRB3* and *NCAPG*; Rubin *et al.* 2012; Chen *et al.* 2018) indicating that fixation or  
25  
26 486 increased frequency for some haplotypes containing breed specific alleles or features differentiating  
27  
28  
29 487 the domestic pool from wild boars could be captured by ROH.

30  
31 488 Runs of homozygosity can complement other methods that have been applied to extract  
32  
33 489 signatures of selection in these pig breeds (Muñoz *et al.* 2018, 2019; Bovo *et al.* 2020a, 2020b) and  
34  
35 490 can provide additional information useful to design conservation plans and mating strategies to  
36  
37  
38 491 maintain the diversity of these pig genetic resources.

## 42 493 **Acknowledgments**

**Data availability**

Genotyping data of the autochthonous breeds can be shared after the signature of an agreement on their use with the TREASURE Consortium. Genotyping data of the commercial breeds can be shared after the signature of an agreement on their use with the University of Bologna.

## Tables

**Table 1.** Runs of homozygosity (ROH) parameters calculated in the 23 pig breeds obtained without any pruning for minor allele frequency (MAF), i.e.  $MAF \geq 0.00$ . Parameters calculated using MAF  $> 0.01$  are reported in Table S4.

Breed	Acronym	nROH (SD) <sup>1</sup>	L <sub>ROH</sub> (SD) <sup>2</sup>	S <sub>ROH</sub> (SD) <sup>3</sup>
Alentejana	AL	50.90 (10.67)	6.49 (2.48)	339.97 (167.31)
Apulo-Calabrese	AC	56.74 (11.67)	14.21 (3.60)	813.75 (266.55)
Basque	BA	106.62 (9.36)	7.21 (1.13)	764.56 (105.38)
Bísara	BI	43.88 (12.93)	7.59 (2.67)	352.18 (211.11)
Black Slavonian	BS	36.61 (14.72)	8.75 (3.29)	336.98 (230.97)
Casertana	CA	45.34 (11.20)	12.63 (4.04)	595.06 (268.90)
CintaSenese	CS	55.62 (15.47)	7.75 (2.28)	424.32 (144.99)
Gascon	GA	75.08 (8.52)	6.97 (1.06)	522.14 (89.18)
Iberian	IB	51.38 (11.97)	6.50 (2.25)	341.52 (148.95)
Krškopljje	KR	34.96 (7.36)	8.62 (2.72)	306.47 (138.31)
Lithuanian indigenous wattle	LIW	42.69 (7.07)	7.69 (1.74)	330.44 (98.97)
Lithuanian White Old Type	LWOT	56.27 (10.16)	6.59 (1.82)	373.55 (133.34)
Majorcan Black	MB	48.50 (10.47)	6.58 (1.95)	327.89 (147.08)
Mora Romagnola	MR	70.35 (7.37)	14.38 (2.48)	1003.13 (139.75)
Moravka	MO	30.14 (12.34)	8.48 (4.36)	289.36 (220.73)
Nero Siciliano	NS	24.15 (10.00)	7.30 (4.91)	207.33 (208.19)
Sarda	SA	27.46 (10.26)	7.77 (4.70)	246.77 (221.24)
Schwäbisch-Hällisches	SHS	49.14 (6.63)	7.28 (2.13)	360.16 (123.64)
Swallow-Bellied Mangalitsa	SBMA	49.96 (8.11)	9.75 (2.04)	483.27 (115.50)
Turopolje	TU	79.76 (15.31)	11.91 (1.78)	955.04 (242.37)
Italian Duroc	IDU	104.00 (10.49)	6.33 (1.03)	655.35 (106.75)
Italian Landrace	ILA	65.56 (8.86)	5.27 (1.08)	347.80 (92.75)
Italian Large White	ILW	62.46 (12.90)	5.52 (1.00)	349.22 (107.11)

<sup>1</sup> nROH: the average total number of ROH and the standard deviation (SD) calculated for each breed.

<sup>2</sup> L<sub>ROH</sub>: the average length of ROH (in Mb) considering all length classes and the standard deviation (SD) calculated for each breed.

<sup>3</sup> S<sub>ROH</sub>: the average sum of all ROH segments (in Mb) by animals considering all length classes and the standard deviation (SD) calculated for each breed.

Italian Landrace	20/48 (42%)	32	75.03	2.34 (2.48)
Italian Large White	20/48 (42%)	12	46.51	3.88 (2.57)

<sup>1</sup> Frequency of the SNPs in a ROH that identifies the threshold to declare a ROH island. The frequency has been calculated dividing the number of animals needed to reach the define level by the number of animals retained after genotyping (see Table S2).

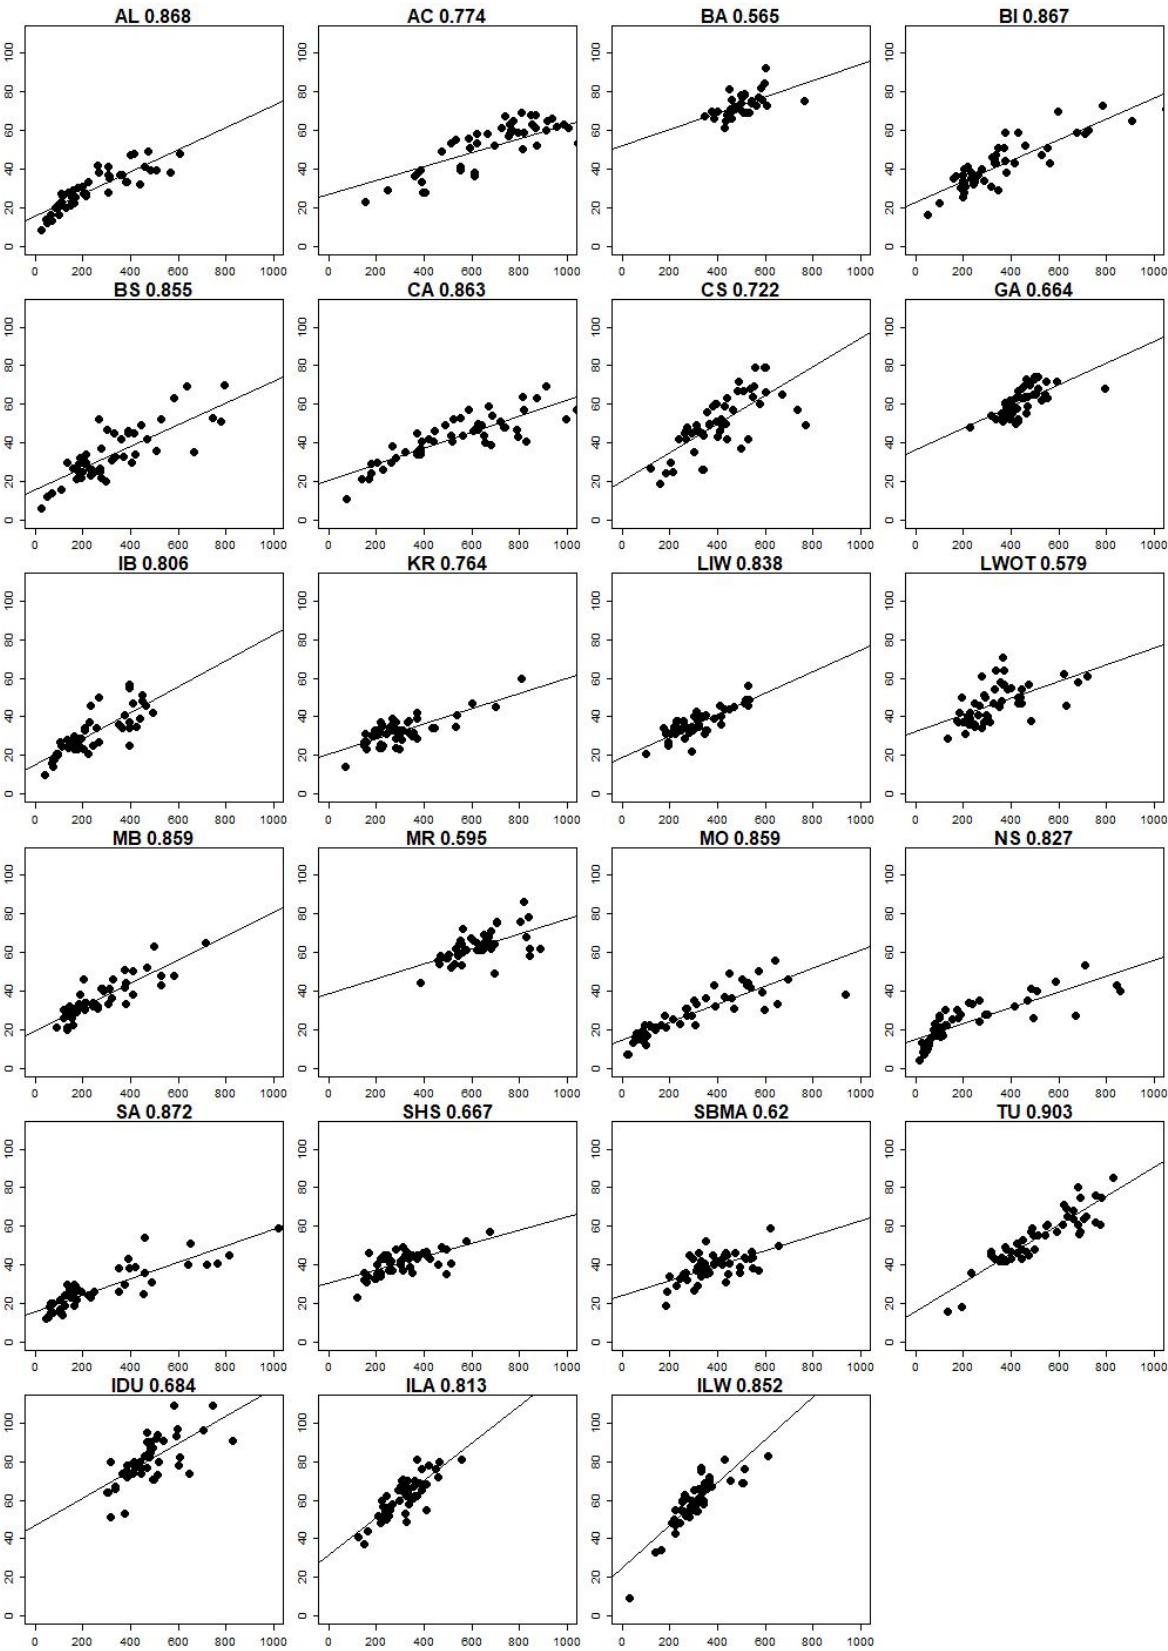

<sup>2</sup> Sum of the length of the chromosome regions in the genome covered by ROH islands in Mb.

<sup>3</sup> Average length of the ROH islands (standard deviation) in Mb.

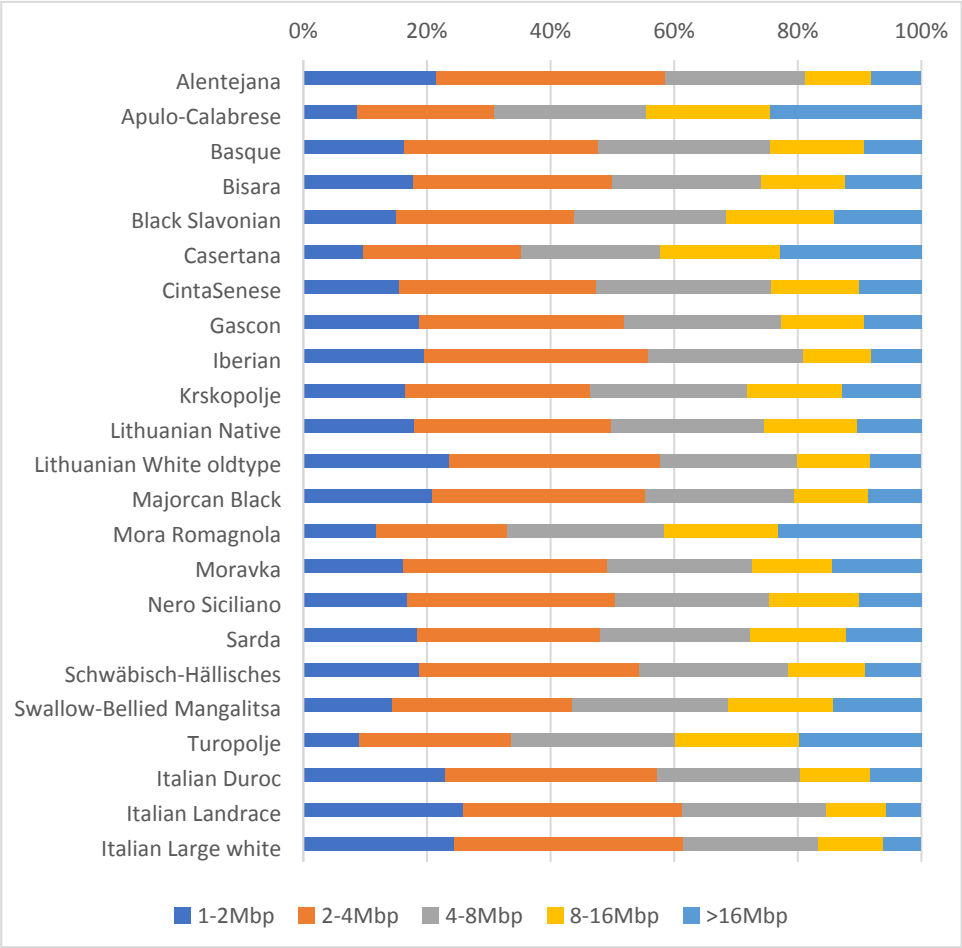

The three blocs indicate the two different thresholds that can be used to define an island. For each block, there is information about: the number of animals that is used as threshold to define ad Island, the number of islands Identified, the total length of genome that is covered by islands, the average length of islands.

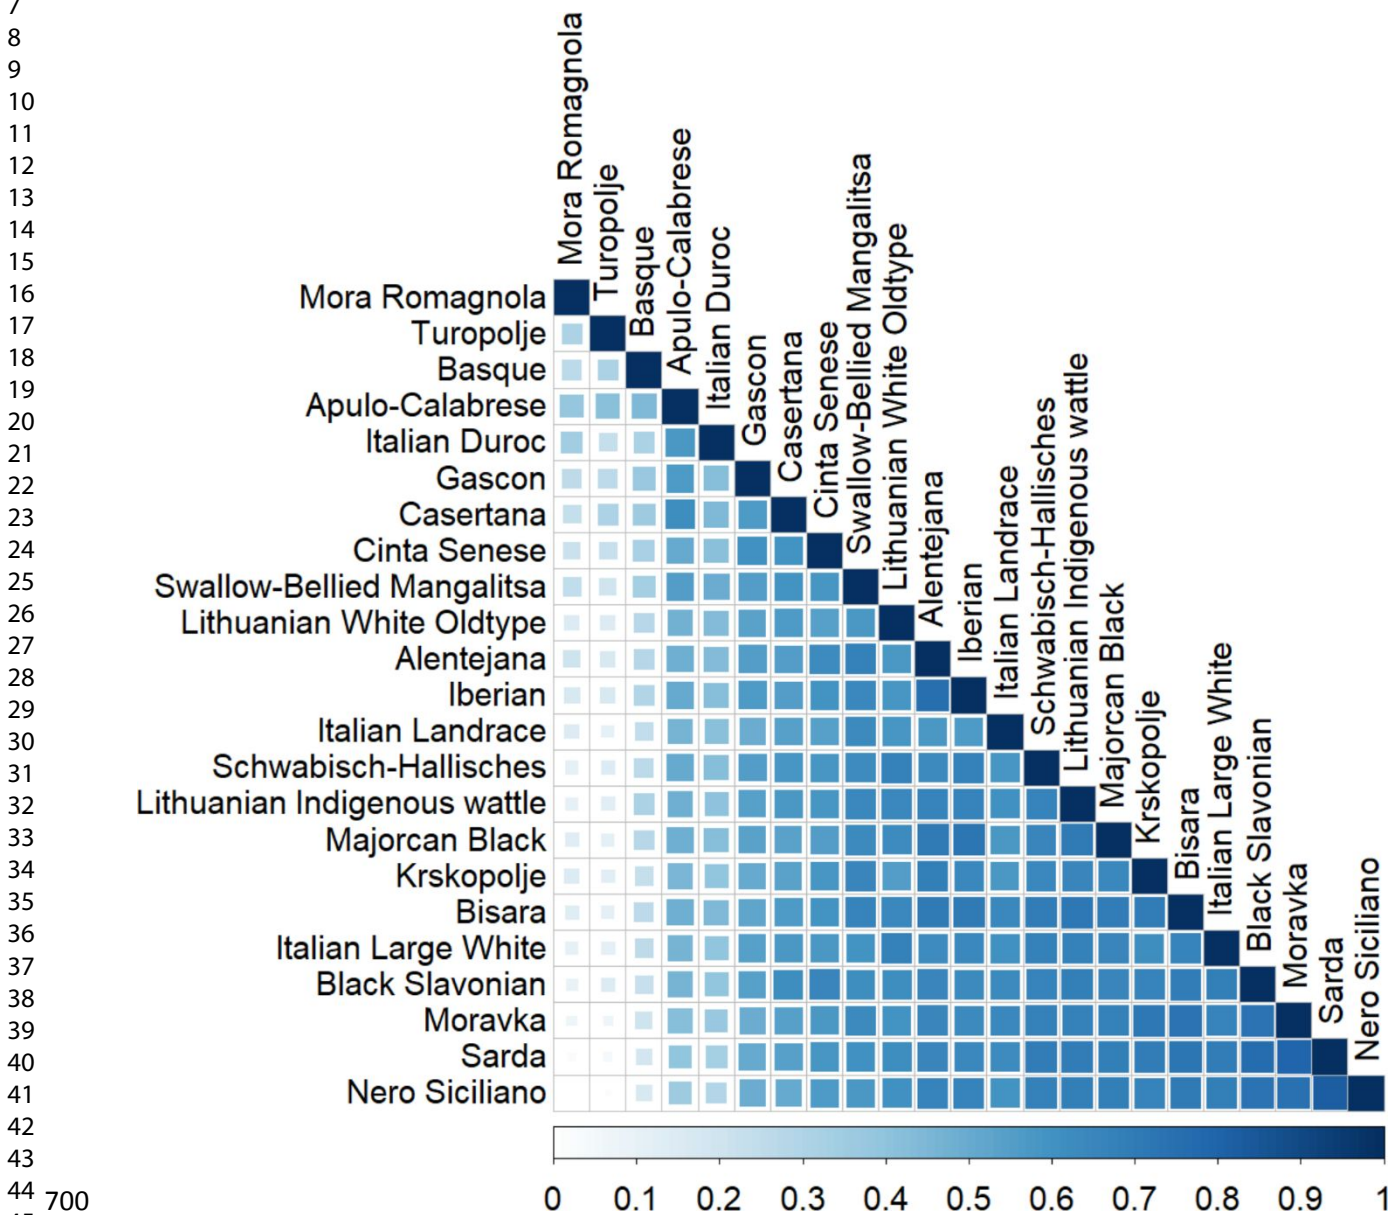

**Figure 4.** Manhattan plots showing ROH islands in a few analysed pig breeds with extreme patterns. The red line indicates the  $S_{ROH}$ -based threshold, the blue line indicates the frequency corresponding to the top 1% most frequent SNP in the population, the green line indicates the 50% of individuals within the population. The y axes indicate the number of animals carrying that SNP in a ROH.

## Supporting information legend

**Table S1:** Analysed breeds, their country and region of origin and other information useful to describe the breeds.

**Table S2:** Number of animals and analysed SNP before and after the filtering steps.

**Table S3.** Effective population size ( $N_e$ ) calculated for each breed.

**Table S4.** Runs of homozygosity (ROH) parameters using minor allele frequency (MAF)  $\geq 0.01$

**Table S5.** Minimum and maximum values for the number and size of ROH ( $n_{ROH}$  and  $L_{ROH}$ , respectively) and for the sum of all ROH segments by animals.

**Table S6.** Proportion of the five different runs of homozygosity (ROH) classes for each breed.

**Table S7.** Mean  $F_{ROH}$  values calculated using different ROH lengths and MAF  $> 0.01$ .

**Table S8.** Average values for several genomic inbreeding measures.

**Table S9.** Correlation between all genomic inbreeding parameters in all breeds.

**Table S10.** The number ROH islands and information on the genome covered.

**Table S11.** ROH Islands and annotations (Excel file).

**Table S12.** Results of the gene enrichment analysis on all ROH Islands.

**Table S13.** Results of the gene enrichment analysis on ROH Islands that overlapped previous work regions identifying selection signature.

**Figure S1.** Multidimensional scaling (MDS) plot of the 23 pig breeds.

**Figure S2.** Genomic inbreeding based on  $F_{ROH}$  across chromosomes ( $F_{ROHSS}$ ).

**Figure S3.** Boxplot of the Inbreeding Coefficients estimated with all the different methods.

**Figure S4.** Boxplot of the Inbreeding Coefficients estimated with all the different methods.

**Figure S5.** Manhattan plots showing ROH island patterns in all investigated pig breeds. The red line indicates the  $S_{ROH}$ -based threshold, the blue line indicates the frequency corresponding to the top 1% most frequent SNP in the population, the green line indicates the 50% of individuals within the population. The y axes indicate the number of animals carrying that SNP in a ROH.
