Shannon Entropy

The concept of entropy was introduced in the early 19th century by Rudolf Julius Emanuel Clausius. It represents a characteristic quantity of the state of a physical system capable of expressing the ability of the system itself to be able to proceed to spontaneous transformations and, consequently, the loss of ability to do work when such transformations occur. In simplified terms, the value of entropy increases when the system undergoes spontaneous variations and therefore loses part of its ability to undergo such variations and perform work. In 1872 Ludwig Boltzmann generalized this concept through the study of statistical mechanics by defining entropy as the degree of disorder of a system. In 1948 Claude Elwood Shannon equated the degree of inaccuracy of a message with disorder. For Shannon, in fact, the entropy of information was the degree of complexity of a message that represents the minimum average number of symbols necessary for the encoding of the message itself. The maximum value for Shannon entropy is two, whereas the minimum is zero. In our analysis we decided to use Shannon entropy (Entropy R package retrieved from <https://cran.r-project.org/web/packages/entropy>) in order to remove those TEs with no significant information ($H \leq 1$). Thirty-thousands up to ~600M were selected after applying the aforementioned cut-off.

Supplementary Table 1

evolutionary recent TEs									
						L1HS / L1P*	HERVK / LTR5Hs	AluY*	SVA
	mapped_transcripts	no.	length	std	unique_TE				
LINE	138,199	385	262.1	94,372		12,775			
LTR	63,563	396	277.3	44,694			1,331		
SINE	196,654	332.3	1.4	180,058				18,068	
SVA	3,513	430	244	1,651					1,651
DNA	22,582	343.1	220	17,662					
Total =	424,511	377.28	200.96	338,437			33,825		
evolutionary recent TEs									
						L1HS / L1P*	HERVK / LTR5Hs	AluY*	SVA
	mapped_transcripts	no.	length	std	unique_TE				
LINE	176,478	362	241.7	118,403		28,377			
LTR	73,888	374	260.6	49,810			2,741		
SINE	212,522	313.2	49.9	186,225				19,336	
SVA	4,047	420	245	1,811					1,811
DNA	22,759	321.4	202.3	16,910					
Total =	489,694	358.12	199.9	373,159			52,265		

Supplementary Table 1 presents the details of the TE-mapping transcripts (their absolute number, length average and std, and how many unique TEs are mapped within each Class. Evolutionary recent TEs include L1HS and L1PA2/3/4, HERVK/LTR5Hs, AluY and SVA and account for 9.9% of all TEs in Converter_{pre} vs Converter_{post} and 14% of all TEs in Converter_{pre} vs NC.

Supplementary Figure 1

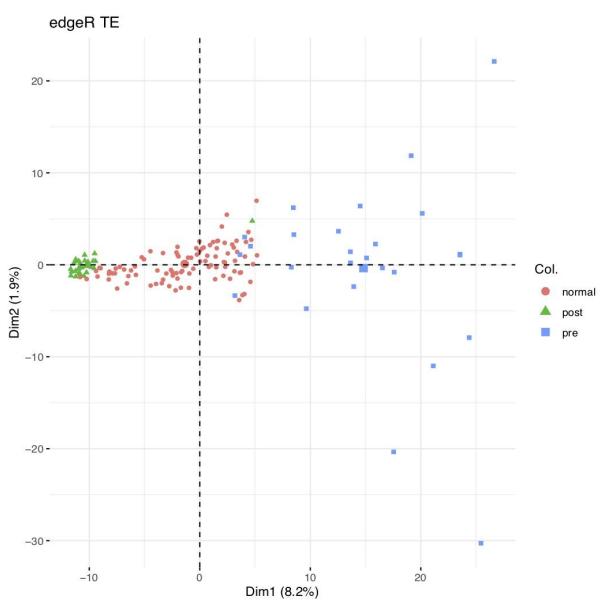

Supplementary Figure 1A shows the absence of any clustering in the heatmap that compare “young” with “old” normal controls. Supplementary Figure 1B shows the results of a PCA analysis for these 2 groups considering the 1,790 DE TEs presenting an equal dispersion of subjects across PC1 and PC2. Supplementary Figure 1C shows a not significant result for age and both PC1 and PC2 in a linear model.
