## General Methods.

${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra were recorded on Varian $400(400 \mathrm{MHz})$ spectrometers. Chemical shifts are reported in ppm from TMS with the solvent resonance as the internal standard (deuterochloroform: 7.24 ppm ). Data are reported as follows: chemical shift, multiplicity ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{dd}=$ doublet doublet, $\mathrm{t}=$ triplet, $\mathrm{td}=$ triple doublet, $\mathrm{dt}=$ double triplet, $\mathrm{q}=$ quartet, sext = sextet, sept = septet, $p=$ pseudo, $b=$ broad, $m=$ multiplet), coupling constants $(\mathrm{Hz}) .{ }^{13} \mathrm{C}-$ NMR spectra were recorded on a Varian $400(100 \mathrm{MHz})$ spectrometers with complete proton decoupling. Chemical shifts are reported in ppm from TMS with the solvent as the internal standard (deuterochloroform: 77.0 ppm ).
GC-MS spectra were taken by El ionization at 70 eV on a Hewlett-Packard 5971 with GC injection. They are reported as: $m / z$ (rel. intense). LC-electrospray ionization mass spectra were obtained with Agilent Technologies MSD1100 single-quadrupole mass spectrometer.
Chromatographic purification was done with 240-400 mesh silica gel. Other anhydrous solvents were supplied by Sigma Aldrich in Sureseal® bottles and used without any further purification. Commercially available chemicals were purchased from Sigma Aldrich, Stream and TCI and used without any further purification. Melting points were determined with Bibby Stuart Scientific Melting Point Apparatus SMP 3 and are not corrected.
$\mathrm{CO}_{2} \geq 99.5 \%$ purity, purchased from SIAD, was used in the Ni-catalyzed tandem C-C $\sigma$-bond carboxylation reaction.
Anhydrous DMF, THF and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ were purchased from Merck and used as received. Zn dust refers to a particle size $<10 \mu \mathrm{~m}$ and was purchased from Merck, having $\geq 98 \%$ purity. All other commercially available starting materials and (non-anhydrous) solvents were purchased from Merck, TCl chemicals, Fluorochem or Alfa Aesar and were used as such without further purification.
Starting materials S1-4 are known compounds and were prepared following literature procedures. ${ }^{[1]}$
XPS spectra were acquired by hemispherical analyser (Phoibos 100, Specs, Germany). Nonmonochromatic Mg Ka excitation was set to 125 W (XR50, Specs, Germany). Survey and highresolution spectra were acquired in Fixed Analyser Transmission mode (FAT) on a large area of c.a. $7 \times 3 \mathrm{~mm}^{2}$, overall energy resolution of 0.9 eV measured on freshly sputtered Silver ( Ag 3d). Spectrometer was calibrated to $\mathrm{Au} 4 \mathrm{f}_{7 / 2}$ peak at 84.0 eV . Static charging effects was corrected by calibrating all spectra to C 1 s 285.0 eV . Fits were performed by using CasaXPS software after Shirley background subtraction. C 1s was fitted by using asymmetric line-shape for aromatic $\mathrm{C}-\mathrm{sp}^{2}$ and symmetric line-shapes (pseudo-voigt) for the $\mathrm{C}-\mathrm{O}$ defects. ${ }^{[2]}$ The binding energies of $C$ 1s synthetic components were: $C=C s^{2}$ at $284.4 \mathrm{eV}, \mathrm{C}=\mathrm{C}^{*} \mathrm{sp}^{2}$ at $283.6 \mathrm{eV}, \mathrm{C}-\mathrm{C}$ $\mathrm{sp}^{3} 285.0 \mathrm{eV}, \mathrm{C}-\mathrm{OH}$ at $286.2 \mathrm{eV}, \mathrm{C}-\mathrm{O}-\mathrm{C}$ at $286.8 \mathrm{eV}, \mathrm{C}=\mathrm{O}$ at 288.2 eV and $\mathrm{O}-\mathrm{C}=\mathrm{O}$ at 289.1 eV.
Solid-state NMR (ssNMR) experiments were recorded on a Bruker Avance III HD spectrometer operating at $850 \mathrm{MHz}{ }^{1} \mathrm{H}$ Larmor frequency ( 20 T ), corresponding to $213 \mathrm{MHz}{ }^{13} \mathrm{C}$ Larmor frequency. The spectrometer was equipped with a 3.2 mm BVT MAS probe head in triple resonance mode. The magic angle spinning (MAS) frequency of the sample was set to $20 \pm$ $1 \cdot 10^{-3} \mathrm{kHz}$ through a Bruker MAS3 Unit. The tablets used for XPS were directly packed in the rotor ${ }^{[3]}$ to ensure a high filling factor of the rotor. In the 1 D direct excitation ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra, the excitation pulse duration was set to $4.15 \mu \mathrm{~s}$, corresponding to a $90^{\circ}$ flip angle, the spectral
window was 468 ppm , and the interscan delays were set to 10 s , which is sufficient to make the experiments quantitative for the present samples. For the $2 \mathrm{D}\left\{{ }^{1} \mathrm{H}\right\}-{ }^{-13} \mathrm{C}$ HETCOR experiments, cross-polarization was achieved by matching the $\mathrm{k}=1$ Hartmann-Hahn condition. ${ }^{[4]}$ The $90^{\circ}$ pulse duration on ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ were set to $4.15 \mu \mathrm{~s}$ and $2.5 \mu \mathrm{~s}$, respectively. The spectral windows for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ were 20 and 350 ppm , respectively. During the ${ }^{1} \mathrm{H}$ magnetization evolution under the chemical shift in the indirect dimension, the FSLG decoupling sequence ${ }^{[5]}$ at 100 kHz was used to suppress ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ dipolar couplings. In these experiments, the interscan delay was set to 1.5 s . The $\left\{{ }^{1} \mathrm{H}\right\}{ }^{13} \mathrm{C}$ HETCOR spectra were processed for denoising as recently proposed by some of us, ${ }^{[6]}$ and processed applying an exponential modulation with 200 Hz line broadening in the direct dimension and a sine-squared window function on the indirect dimension. ${ }^{[5]}$

## Preparation and Characterization of Starting Materials 1

In a heat-gun dried round-bottom flask, equipped with magnetic stirrer, reflux condenser and dropping funnel, dry THF ( 2.0 mL ), Mg (turnings, $1.5 \mathrm{mmol}, 36 \mathrm{mg}$ ) and iodine (one crystal) were added under $\mathrm{N}_{2}$. The dropping funnel was charged with dry THF ( 3.0 mL ) and the desired aryl bromide ( 1.13 mmol ). The mixture in the flask was heated to $50^{\circ} \mathrm{C}$ and the solution of aryl bromide was added dropwise to the flask under vigorous stirring (the disappearance of the brown color of iodine indicated that the Grignard reagent started forming). After the addition was completed the resulting mixture was heated to reflux for 1 h then cooled to $0^{\circ} \mathrm{C}$. A solution of the desired cyclobutanone ( $\mathbf{S 1}$ for compounds 1a-h, $\mathbf{S 3}$ for $\mathbf{1 i}, \mathbf{S 2}$ for $\mathbf{1} \mathbf{j}$, and $\mathbf{S 4}$ for $\mathbf{1 k} \mathbf{- 0}, 0.75 \mathrm{mmol}$ in 2.0 mL of dry THF) was added dropwise through the dropping funnel and the resulting suspension was warmed to room temperature and stirred until TLC indicated full consumption of the starting material (ca. 2 h). A saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}_{(\text {(aq.) }}$ was then added cautiously ( 5 mL ) followed by $\mathrm{Et}_{2} \mathrm{O}$ $(10 \mathrm{~mL})$ and the biphasic mixture was transferred to a separatory funnel where the phases were separated. The aqueous phase was extracted with $\mathrm{Et}_{2} \mathrm{O}(2 \times 5 \mathrm{~mL})$, the combined organic phases were washed with brine ( 10 mL ), dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, concentrated in vacuo and finally purified by Flash Chromatography $\left(\mathrm{SiO}_{2}\right)$ to give the respective cyclobutanols 1 as white solids (mixture of diastereoisomers).

## Characterization of compounds 1

1a (1:1 diastereomeric mixture). White solid. FC eluent: cHex:EtOAc: 10:1. ## Optimized general procedure for the GO-promoted preparation of indenes 2

A screw-cap-vial was charged with reagent grade EtOAc ( 1.0 ml ), the desired cyclobutanol 1 ( 0.1 mmol ) and GO (100 wt\% with respect to 1 ). The reaction mixture was warmed at $90{ }^{\circ} \mathrm{C}$ and stirred at the same temperature overnight. Removal of the GO by filtration (Celite pad) and subsequent purification via flash chromatography led to the isolation of compounds 2 (generally as a mixture of isomers).

## Optimized general procedure for the GO-promoted preparation of dienes 3

A screw-cap-vial was charged with reagent grade EtOAc ( 3.5 ml ), the desired cyclobutanol 1 ( 0.1 mmol ) and GO ( $20 \mathrm{wt} \%$ with respect to 1 ). The reaction mixture was warmed at $90^{\circ} \mathrm{C}$ and stirred at the same temperature overnight. Removal of the GO by filtration (Celite pad) and subsequent purification via flash chromatography led to the isolation of compounds $\mathbf{3}$ (generally as a mixture of isomers).
