## Chemistry

(S)-, (R)-Fmoc-Asp-OBn, (S)-4, (R)-4. A mixture of either (S) or (R)-Fmoc-Asp(OtBu)-OH (1.0 mmol), tetra-butylammonium bromide ( 1.0 mmol ), and anhydrous $\mathrm{K}_{2} \mathrm{CO}_{3}(1.1 \mathrm{mmol})$ in acetonitrile ( 5 mL ) was stirred at RT for 20 min . A solution of benzyl bromide ( 1.1 mmol ) in acetonitrile ( 4 mL ) was then added dropwise under vigorous stirring. The mixture was stirred for 12 h at RT, then the precipitate was filtered off, and the filtrate was evaporated to dryness. The resulting crude material was dissolved in EtOAc, and the organic layer was washed three times with sat. $\mathrm{NaHCO}_{3}, \mathrm{H}_{2} \mathrm{O}$ and brine, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and finally the solvent was evaporated at reduced pressure to afford the product as a white solid, used without further isolation. (S)-Fmoc-Asp(OtBu)-OBn $(98 \%, 85 \%$ pure as determined by RP HPLC, General Methods). ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{30} \mathrm{H}_{31} \mathrm{NO}_{6} \mathrm{Na}\right]^{+} 524.2$, found $524.2[\mathrm{M}+\mathrm{Na}]^{+}$. ( $R$ )-Fmoc-Asp(OtBu)-OBn $(94 \%, 90 \%$ pure), ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{30} \mathrm{H}_{31} \mathrm{NO}_{6} \mathrm{Na}\right]^{+} 524.2$, found $524.2[\mathrm{M}+\mathrm{Na}]^{+}$.

Either $(S)$ - or $(R)-\mathrm{Asp}(\mathrm{OtBu})-\mathrm{OBn}$ were treated with $25 \% \mathrm{TFA}$ in $\mathrm{DCM}(4 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$ under stirring for 3 $h$. The solvent was distilled at reduced pressure, then ice-cold water was added to the residue and the suspension was allowed to stir overnight. The resulting precipitate was collected by filtration, dried under high vacuum and used without further purifications. ( $S$ )-4 ( $98 \%, 89 \%$ pure as determined by RP HPLC, General Methods), ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{26} \mathrm{H}_{24} \mathrm{NO}_{6}\right]^{+} 446.2$, found $446.2[\mathrm{M}+\mathrm{H}]^{+} .(R)-4(95 \%, 92 \%$ pure $)$, ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{26} \mathrm{H}_{24} \mathrm{NO}_{6}\right]^{+} 446.2$, found $446.3[\mathrm{M}+\mathrm{H}]^{+}$.

Scheme S1. (A) Preparation of (S)- or (R)-Fmoc-Asp-OBn, (S)-4 or (R)-4. Reagents and conditions: $i$ ) benzyl-Br, $\mathrm{Bu}_{4} \mathrm{NBr}, \mathrm{K}_{2} \mathrm{CO}_{3}$; ii) TFA, DCM, RT. (B) Preparation of $(S)$ - or ( $R$ )-Boc-Phu-OH ( $S$ )-8 or ( $R$ )-8. Reagents and conditions: i) $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HNO}_{3}, 0^{\circ} \mathrm{C}, 1 \mathrm{~h}$; ii) $\mathrm{Boc}_{2} \mathrm{O}, \mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{H}_{2} \mathrm{O} /$ dioxane, $\mathrm{RT}, 12 \mathrm{~h}$; iii) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, \mathrm{MeOH}, \mathrm{RT}, 3 \mathrm{~h}$; iv) otolyl isocyanate, DMF, RT, 3 h .
$(S)-,(R)-4-\mathrm{NO}_{2}-\mathrm{Phe},(S)-5,(R)-5$. Phenylalanine $(1.0 \mathrm{mmol})$ was added in small portion to conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ $(6.0 \mathrm{mmol})$ until complete dissolution. The mixture was then cooled to $0^{\circ} \mathrm{C}$, and conc. $\mathrm{HNO}_{3}(0.65 \mathrm{mmol})$ was added dropwise. The reaction was stirred for 1 h at $0^{\circ} \mathrm{C}$. Then, ice-cold $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was slowly added to the reaction mixture and stirred for additional 15 min . The mixture was heated to $100^{\circ} \mathrm{C}$ for 1 min and cooled to RT, then pH was corrected to $5-6$ with $28 \% \mathrm{NH}_{4} \mathrm{OH}$. The mixture was concentrated at reduced pressure and kept overnight for crystallization. The crystals were filtered, washed with water ( 5 mL ) and dried under high vacuum to give $(S)$ - or $(R)-5$ as white solids. $(S)-\mathbf{5}(85 \%, 95 \%$ pure as determined by RP HPLC), ESI-MS $m / z$ calcd. for $\left[\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{2} \mathrm{O}_{4}\right]^{+} 211.1$, found $211.2[\mathrm{M}+\mathrm{H}]^{+} .(R)-6(97 \%, 94 \%$ pure), ESI-MS $\mathrm{m} / \mathrm{z}$ calcd. for $\left[\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{2} \mathrm{O}_{4}\right]^{+} 211.1$, found $211.1[\mathrm{M}+\mathrm{H}]^{+}$.
$(S)$-, $(R)$-Boc-4- $\mathrm{NO}_{2}$-Phe, $(S)-\mathbf{6},(R)-6 . \mathrm{Boc}_{2} \mathrm{O}(1.2 \mathrm{mmol})$ was added to a suspension of $(S)$ - or $(R)-5(1.0$ $\mathrm{mmol})$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}(2.0 \mathrm{mmol})$ in $1: 1 \mathrm{H}_{2} \mathrm{O} /$ Dioxane $(10 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$, and the mixture was stirred overnight at RT. Dioxane was distilled under reduced pressure, the alkaline aqueous layer was adjusted to $\mathrm{pH} 3-4$ with 0.5 M HCl , then the mixture was extracted three times with EtOAc ( 10 mL ). The combined organic phases were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was removed at reduced pressure, to afford $(S)-$ or $(R)$-6, which were used without further purifications. (S)-6 $(90 \%, 90 \%$ pure as determined by RP HPLC, General

Methods), ESI-MS $m / z$ calcd. for $\left[\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{6} \mathrm{Na}\right]^{+} 333.1$, found $333.2[\mathrm{M}+\mathrm{Na}]^{+}$. ( $R$ ) -6 ( $84 \%, 90 \%$ pure), ESI-MS $m / z$ calcd. for $\left[\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{6} \mathrm{Na}\right]^{+} 333.1$, found $333.1[\mathrm{M}+\mathrm{Na}]^{+}$.
$(S)$-, $(R)$-Boc-4- $\mathrm{NH}_{2}$-Phe, $(S)-7,(R)-7$. The nitro group of $(S)$ - or $(R)-6(1.0 \mathrm{mmol})$ was reduced by hydrogenation in MeOH in the presence of $10 \% w / w \mathrm{Pd} / \mathrm{C}$ while stirring for 3 h at RT. The mixture was filtered over a Celite ${ }^{\circledR}$ pad and the solvent was removed under reduced pressure. Then, $\mathrm{Et}_{2} \mathrm{O}$ was added to the residue and the suspension was allowed to stir overnight. The resulting precipitate was collected by filtration, dried under high vacuum and used without further purifications: (S)-7 ( $45 \%, 95 \%$ pure as determined by RP HPLC, General Methods), ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{~N}_{2} \mathrm{O}_{4}\right]^{+} 281.1$, found $281.1[\mathrm{M}+\mathrm{H}]^{+}$, 181.2 [M$\mathrm{Boc}+\mathrm{H}]^{+}$. $(R)-7(50 \%, 95 \%$ pure $)$, ESI MS $m / z$ calcd. for $\left[\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{~N}_{2} \mathrm{O}_{4}\right]^{+} 281.1$, found $281.1[\mathrm{M}+\mathrm{H}]^{+}$.
(S)-, (R)-Boc-Phu-OH, (S)-8, (R)-8. o-Tolyl isocyanate ( 1.1 mmol ) was added dropwise to a solution of either $(S)-7$ or $(R)-7(1.0 \mathrm{mmol})$ in DMF ( 3 mL ) at RT under $\mathrm{N}_{2}$ atmosphere. The mixture was stirred for 3 h , then ice-cold $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$ was added and the precipitate $(S)-\mathbf{8}$ or $(R)-\mathbf{8}$ was collected as a brownish solid by filtration. ( S ) $\mathbf{8} \mathbf{8}(76 \%, 95 \%$ pure as determined by RP HPLC, General Methods), ESI MS $\mathrm{m} / \mathrm{z}$ calcd. for $\left[\mathrm{C}_{22} \mathrm{H}_{27} \mathrm{~N}_{3} \mathrm{O}_{5} \mathrm{Na}\right]^{+} 436.1$, found $436.2[\mathrm{M}+\mathrm{Na}]^{+}, 314.2[\mathrm{M}-\mathrm{Boc}+\mathrm{H}]^{+} .(R)-\mathbf{8}(67 \%, 95 \%$ pure $)$, ESI MS $\mathrm{m} / \mathrm{z}$ calcd. for $\left[\mathrm{C}_{22} \mathrm{H}_{27} \mathrm{~N}_{3} \mathrm{O}_{5} \mathrm{Na}\right]^{+} 436.1$, found $436.2[\mathrm{M}+\mathrm{Na}]^{+}$, $314.1[\mathrm{M}-\mathrm{Boc}+\mathrm{H}]^{+} .{ }^{1} \mathrm{H}$ NMR ( 400 MHz , DMSOd $_{6}$ ) $\sigma 7.63(\mathrm{~d}, 1 \mathrm{H}), 7.43(\mathrm{~d}, 1 \mathrm{H}), 6.85-7.25(\mathrm{~m}, 6 \mathrm{H}), 4.23(\mathrm{~m}, 1 \mathrm{H}), 3.15(\mathrm{dd}, 1 \mathrm{H}), 2.9(\mathrm{dd}, 1 \mathrm{H}), 2.3(\mathrm{~s}$, 3 H ), 1.4 ( $\mathrm{s}, 9 \mathrm{H}$ ).

B

(S)-21

Scheme S2. (A) Preparation of (R)-N-Boc- $\beta^{3}$-homoAla 20. Reagents and conditions: $i$ ) NMM, ethyl chloroformate, THF, $0^{\circ} \mathrm{C}$ - RT, 15 min , then $\mathrm{NaBH}_{4}, 0^{\circ} \mathrm{C}-\mathrm{RT}, 10 \mathrm{~min}$; ii) $\mathrm{PPh}_{3}$, $\mathrm{I}_{2}$, imidazole, DCM, reflux, 3 h ; iii) KCN, DMSO, 60 ${ }^{\circ} \mathrm{C}, 4 \mathrm{~h}$; $i v$ ) HCl 3 M , reflux, 12 h ; v) Fmoc-Cl, $\mathrm{Na}_{2} \mathrm{CO}_{3}$, in $1: 1 \mathrm{H}_{2} \mathrm{O} /$ dioxane at RT. (B) Synthesis of Fmoc- $(R)$-Asppropylamide. Reagents and conditions: i) n-propylamine, EDC•HCl, HOBt, TEA, DM1F/DCM, RT, 3 h ; ii) TFA, DCM, RT, 1 h .
(R)-tBu-(l-hydroxypropan-2-yl)carbamate, 17. To a stirred solution of NMM (1.1 mmol) and Boc-(R)-Ala-OH ( 1.0 mmol ) in dry THF ( 5 mL ), ethyl chloroformate ( 1.1 mmol ) was added dropwise at $0{ }^{\circ} \mathrm{C}$ under inert atmosphere. After 15 min , the solution was filtered and the precipitated was washed with THF ( 5 mL ). The filtrates were collected, and a solution of $\mathrm{NaBH}_{4}(1.25 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(5 \mathrm{~mL})$ was then added dropwise at $0^{\circ} \mathrm{C}$ under stirring. The mixture was risen to RT, and after 10 min the solvent was distilled under reduced pressure. The residue was re-dissolved in EtOAc ( 30 mL ) and the suspension was washed with $\mathrm{H}_{2} \mathrm{O}$ and brine ( 5 mL each), then dried $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was distilled under reduced pressure, giving $\mathbf{1 7}(89 \%)$ as a yellow oil, which was used without further purifications. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 4.67(\mathrm{br} \mathrm{s}, 1 \mathrm{H}$, NH), $3.78-3.60(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH} \alpha), 3.50(\mathrm{dd}, J=13.8,7.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CH} \beta$ ), 3.26 (dd, $J=12.4,7.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CH} \beta$ ), $1.43(\mathrm{~s}, 9 \mathrm{H}, \mathrm{tBu}), 1.27\left(\mathrm{~d}, J=6.8 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}\right)$. ESI-MS $\mathrm{m} / \mathrm{z}$ calcd. for $\left[\mathrm{C}_{8} \mathrm{H}_{18} \mathrm{NO}_{3}\right]^{+} 176.1$, found 176.2 $[\mathrm{M}+\mathrm{H}]^{+}$.
(R)-tBu-(1-cyanopropan-2-yl)carbamate, 19. To a stirred solution of triphenylphosphine ( 1.25 mmol ) in dry $\operatorname{DCM}(10 \mathrm{~mL}), \mathrm{I}_{2}(1.3 \mathrm{mmol})$ was added at RT under inert atmosphere. After 15 min , imidazole ( 2.5 $\mathrm{mmol})$ was added and the mixture was stirred for additional 15 min . A solution of the crude $\mathbf{1 7}(1.0 \mathrm{mmol})$ in
dry $\operatorname{DCM}(5 \mathrm{~mL})$, was added and the mixture was heated to reflux for 3 h . Then the mixture was cooled and diluted with $\operatorname{DCM}(40 \mathrm{~mL})$, and washed with $10 \%$ aq $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{5}(20 \mathrm{~mL})$ and brine $(20 \mathrm{~mL})$. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent was evaporated at reduced pressure. The crude iodide $\mathbf{1 8}$ so obtained was then dissolved in dry DMSO $(30 \mathrm{~mL})$ and $\mathrm{KCN}(2.0 \mathrm{mmol})$ was added in one portion. The mixture was stirred under inert atmosphere at $60^{\circ} \mathrm{C}$ for 4 h . The solution was then poured into water ( 10 mL ), and the mixture was extracted twice with $\operatorname{EtOAc}(40 \mathrm{~mL})$. The organic layer was washed with brine ( 20 mL ) and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and then evaporated at reduced pressure. The crude residue was purified by flash chromatography over silica gel (eluent cyclohexane/EtOAc 80:20) to give $\mathbf{1 9}$ ( $52 \%$ over two steps).

Fmoc- $(R)-\beta^{3}$-homoAla 20. The nitrile $19(1.0 \mathrm{mmol})$ was dissolved in $6 \mathrm{M} \mathrm{HCl}(10 \mathrm{~mL})$ and heated to reflux for 12 h . The reaction mixture was then cooled at $0^{\circ} \mathrm{C}$ and neutralized with 2 M NaOH solution. The mixture was concentrated under reduced pressure to afford $\beta^{3}$-homoAla as HCl salt. The resulting salt was suspended in a mixture of $1: 1 \mathrm{H}_{2} \mathrm{O} /$ dioxane $(5 \mathrm{~mL})$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}(2.0 \mathrm{~mol})$ and finally $\mathrm{Fmoc}-\mathrm{Cl}(1.0 \mathrm{mmol})$ was added at $0{ }^{\circ} \mathrm{C}$. The reaction was stirred at RT overnight, then the mixture was concentrated under reduced pressure, and the basic aqueous layer was adjusted to $\mathrm{pH} 3-4$ with 0.5 M HCl , and the mixture was extracted three times with $\mathrm{EtOAc}(20 \mathrm{~mL})$. The combined organic phases were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concentrated under reduced pressure. The residue was purified by flash chromatography over silica gel (eluent cyclohexane/EtOAc/AcOH 60:40:1) to afford $20(55 \%)$. ESI-MS $m / z$ calcd. for $\left[\mathrm{C}_{19} \mathrm{H}_{20} \mathrm{NO}_{4}\right]^{+} 326.1$, found $326.2[\mathrm{M}+\mathrm{H}]^{+}$.

Fmoc-( $R$ )-Asp-N-propylamide 21. A mixture of Fmoc-( $R$ )-Asp(OtBu)-OH (1.2 mmol), EDC•HCl (1.5 eq ), $\mathrm{HOBt}(1.5 \mathrm{eq})$ and TEA ( 3.0 eq ) in 3:1 DMF/DCM ( 5 mL ) was stirred at RT for 10 min , then $n$ propylamine ( 1.5 mmol ) was added, and the mixture was stirred under $\mathrm{N}_{2}$ at RT for 3 h . Then the solvent was distilled at reduced pressure, and the residue was purified by flash chromatography over silica gel (eluent cyclohexane/EtOAc 70:30) to afford Fmoc-(R)-Asp(OtBu)-N-propylamide ( $69 \%$ ). ${ }^{1} \mathrm{H}$-NMR ( 400 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 7.78(\mathrm{~d}, J=7.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{ArH}), 7.60(\mathrm{~d}, J=7.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{ArH}), 7.42(\mathrm{t}, J=7.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{ArH})$, $7.33(\mathrm{t}, J=7.4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{ArH}), 6.47$ (br.t, 1 H , propylNH), 5.97 (d, $J=8.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{AspNH}$ ), 4.45 (d, $J=6.8$ $\left.\mathrm{Hz}, 2 \mathrm{H}, \mathrm{FmocCH}_{2}\right), 4.23(\mathrm{~m}, 1 \mathrm{H}, \mathrm{AspH} \alpha), 3.22\left(\mathrm{q}, J=5.9 \mathrm{~Hz}, 2 \mathrm{H}\right.$, propylCH$\left._{2}\right), 2.93(\mathrm{dd}, J=17.0,3.8 \mathrm{~Hz}$, $1 \mathrm{H}, \mathrm{AspH} \beta), 2.60(\mathrm{dd}, J=17.2,6.8 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{AspH} \beta), 1.57-1.48\left(\mathrm{~m}, 2 \mathrm{H}, \operatorname{propylCH}_{2}\right), 1.46(\mathrm{~s}, 9 \mathrm{H}, t-\mathrm{Bu}), 0.91$ $\left(\mathrm{t}, J=7.4 \mathrm{~Hz}, 3 \mathrm{H}\right.$, propylCH 3 ). ESI-MS $m / z$ calcd. for $\left[\mathrm{C}_{26} \mathrm{H}_{33} \mathrm{~N}_{2} \mathrm{O}_{5}\right]^{+} 453.2$, found $453.0[\mathrm{M}+\mathrm{H}]^{+}$. Removal of $t \mathrm{Bu}$-protecting group was performed with $25 \%$ TFA in DCM ( 4 mL ) at $0^{\circ} \mathrm{C}$ under stirring for 3 h . Thereafter the solvent was distilled at reduced pressure and the residue was triturated in $\mathrm{Et}_{2} \mathrm{O}(10 \mathrm{~mL})$, giving 21 in quantitative yield, directly used in the next step without further purifications. ESI-MS $\mathrm{m} / \mathrm{z}$ calcd. for $\left[\mathrm{C}_{22} \mathrm{H}_{25} \mathrm{~N}_{2} \mathrm{O}_{5}\right]^{+} 397.2$, found $397.0[\mathrm{M}+\mathrm{H}]^{+}$.

Figure S1
Degradation of BIO1211, 3a, 3c in mouse serum. Samples were collected from the incubation solution at the indicated times. Peptide stability was determined using an RPHPLC ESI-MS analysis (described in the Methods). Values are presented as mean $\pm$ SD ( $\mathrm{n}=3$ ).

Cell culture. Jurkat E6.1 (expressing $\alpha_{4} \beta_{1}$ and $\alpha_{L} \beta_{2}$ integrin), K562 (expressing $\alpha_{5} \beta_{1}$ integrin) and HL60 (expressing $\alpha_{M} \beta_{2}$ integrin) cell lines were purchased from ATCC (Rockville, MD, USA); these cells were routinely cultured in RPMI-1640 (Life Technologies) supplemented with glutamine and $10 \%$ FBS. RPMI8866 cells were a kind gift from Prof. A. Santoni (Mayo Foundation for Medical Education and Research, Rochester, MN, USA); RPMI8866 cells were routinely grown in RPMI-1640 enriched with $10 \%$ FBS, 5 mM Hepes and 0.5 mM sodium pyruvate and usually kept in 50 mL of culture medium and allowed to form large clumps. Cells were grown at $37{ }^{\circ} \mathrm{C}$ under $5 \% \mathrm{CO}_{2}$ humidified atmosphere. 40 h before the adhesion assays, K562 and HL60 cells were treated with 25 nM or 40 nM phorbol 12-myristate 13-acetate (PMA; Sigma-Aldrich), respectively, to induced cell differentiation and to increased $\alpha_{5} \beta_{1}$ or $\alpha_{M} \beta_{2}$ integrin expression on cell surface (Baiula et al., 2016).

Cell adhesion assays. Concentration-response curves, obtained from cell adhesion assays performed in presence of increasing concentrations of LDV-CPPs, are shown in the following figures.

Figure S2 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{4} \beta_{1^{-}}$ mediated Jurkat cell adhesion to FN. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Figure S3 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{4} \beta_{1^{-}}$ mediated Jurkat cell adhesion to VCAM-1. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Figure S4 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{4} \beta_{7}-$ mediated RPMI8866 cell adhesion to MAdCam-1. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Figure S5 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{M} \beta_{2^{-}}$ mediated HL60 cell adhesion to FN. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Figure S6 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{\mathrm{L}} \beta_{2^{-}}$ mediated Jurkat cell adhesion to ICAM-1. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Figure S7 Concentration-response curves obtained from cell adhesion assays: evaluation of CPPs effects on $\alpha_{5} \beta_{1^{-}}$ mediated K562 cell adhesion to FN. Values represent the mean $\pm$ SD of three independent experiments carried out in quadruplicate.

Solid-Phase Binding Assays. Binding curves deriving from solid-phase binding assays are shown in the following figures.

Figure S8 Binding assay curves for $\alpha_{4} \beta_{1} /$ FN in presence of increasing concentrations of LDV CPPs. Values represent the mean $\pm$ SD of three independent experiments carried out in triplicate.

Figure S9 Binding assay curves for $\alpha_{4} \beta_{7} /$ MAdCAM-1 in presence of increasing concentrations of LDV CPPs. Values represent the mean $\pm$ SD of three independent experiments carried out in triplicate.

Figure S10 Binding assay curves for $\alpha_{M} \beta_{2} /$ fibrinogen in presence of increasing concentrations of LDV CPPs. Values represent the mean $\pm$ SD of three independent experiments carried out in triplicate.

Figure S11 Binding assay curves for $\alpha_{\mathrm{L}} \beta_{2} /$ ICAM-1 in presence of increasing concentrations of LDV CPPs. Values represent the mean $\pm$ SD of three independent experiments carried out in triplicate.

Figure S12 Binding assay curves for $\alpha_{5} \beta_{1} / F N$ in presence of increasing concentrations of LDV CPPs. Values represent the mean $\pm \mathrm{SD}$ of three independent experiments carried out in triplicate.

## Correlation between adhesion assay-determined potency and ligand binding affinity of LDV CPPs.

The correlation was calculated on the basis of experimental data obtained for the LDV CPPs whose ligand binding affinities and potencies were obtained by solid-phase binding assays and cell adhesion assays, respectively. This evaluation was performed only for $\alpha_{4} \beta_{1} /$ FN, $\alpha_{4} \beta_{1} /$ VCAM -1 and $\alpha_{L} \beta_{2} /$ ICAM -1 having sufficient active compounds to conduct a proper analysis.

Figure S13 Relation between experimentally determined potencies ( $\mathrm{IC}_{50} / \mathrm{EC}_{50}$ deriving from cell adhesion assays) and ligand binding affinities ( $\mathrm{IC}_{50}$ deriving from solid-phase binding assays) of the LDV CPPs. The $\mathrm{IC}_{50} / \mathrm{EC}_{50}$ values $\pm$ S.E. are obtained by Tables 1-3. Correlation was measured using Pearson ( $\mathrm{r}_{\mathrm{P}}$ ) correlation coefficient.

Variable temperature (VT) analysis of the CPPs. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ experiments in DMSO- $d_{6} / \mathrm{H}_{2} \mathrm{O}$ (8:2) were recorded at diverse temperatures to determine if the amide protons were involved in intramolecular hydrogen bonding or were solvent exposed (Table S2). Generally, hydrogen bonded amide NH signals display comparatively lower $\Delta \delta / \Delta \mathrm{T}$ values, $|\Delta \delta / \Delta \mathrm{T}|<2.0 \mathrm{ppb} \mathrm{K}^{-1}$, as compared to solvent-exposed amide. Since the viscosity of the cryo-mixture is temperature-dependent, the conformational equilibrium could change at diverse temperatures, altering the resonance pattern. However, as showed by ${ }^{1} \mathrm{H}$-NMR spectra, the CH resonances were perfectly maintained over the range of temperatures suggesting that the global conformations were not significantly altered. As reported in the Table, 3a showed much lower $|\Delta \delta / \Delta \mathrm{T}|$ values for $\mathrm{Val}^{4} \mathrm{NH}$ and isoAsp ${ }^{5} \mathrm{NH}$, suggesting that these amide protons could be involved in strong hydrogen bonds $\left(|\Delta \delta / \Delta \mathrm{T}|<1 \mathrm{ppb} \mathrm{K}^{-1}\right)$. The analysis of $\mathbf{3 b}$ (Table 2) supported the presence of weak hydrogen bonds on $\mathrm{Val}^{4} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{t}=-1.9 \mathrm{ppb} \mathrm{K}^{-1}\right)$ and isoAsp ${ }^{5} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{t}=-2.2 \mathrm{ppb} \mathrm{K}^{-1}\right)$. For $\mathbf{3 c}($ Table S2), the very scarce dependence of chemical shifts from temperature supported a strong hydrogen bond on $\operatorname{Asp}^{3} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{t}=-0.3 \mathrm{ppb} \mathrm{K}^{-1}\right)$. Finally, the VT NMR parameters of $\mathbf{3 d}$ led to predict a very strong hydrogen bond on $\operatorname{Asp}^{3} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{t}=+0.4 \mathrm{ppb} \mathrm{K}^{-1}\right)$, and possibly a weaker hydrogen bonds for $\mathrm{Phu}^{1} \mathrm{NH}$ and $\mathrm{Leu}^{2} \mathrm{NH}$ ( $\Delta \delta / \Delta \mathrm{t}=-2.1$ and $-2.9 \mathrm{ppb} \mathrm{K}^{-1}$, respectively).

The analysis of remaining CPPs showed the same trends of $\Delta \delta / \Delta \mathrm{t}$ parameters as the parent peptides, suggesting that the hydrogen-bonding patterns and secondary structure elements were maintained. The CPPs 11a, 12a and 13, showed comparatively lower $|\Delta \delta / \Delta T|$ values for $V a{ }^{4}{ }^{4} \mathrm{NH}$ and for the amide proton of the $\beta$ amino acid at position 5 , which is quite similar to the parent peptide 3a. And the VT NMR parameters suggested the formation of extra hydrogen bonds involving Asp ${ }^{3} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{T}=-2.2 \mathrm{ppb} \mathrm{K}^{-1}\right)$, Ala ${ }^{3} \mathrm{NH}(\Delta \delta / \Delta \mathrm{T}$ $\left.=+1.6 \mathrm{ppb} \mathrm{K}^{-1}\right)$ and Phu ${ }^{1} \mathrm{NH}\left(\Delta \delta / \Delta \mathrm{T}=-1.7 \mathrm{ppb} \mathrm{K}^{-1}\right)$ in CPPs 11a, 12a and $\mathbf{1 3}$ respectively. The VT-NMR analyses of $\mathbf{1 1} \mathbf{c}$ and $\mathbf{1 2 c}$ confirmed the hydrogen bonding network as for the parent $\mathbf{3 c}$, albeit with slightly different $\Delta \delta / \Delta \mathrm{T}$ values (for 11c $\mathrm{Asp}^{3} \mathrm{NH} \Delta \delta / \Delta \mathrm{T}=-0.7 \mathrm{ppb} \mathrm{K}^{-1}$, for $\mathbf{1 2 c} \mathrm{Ala}^{3} \mathrm{NH} \Delta \delta / \Delta \mathrm{T}=-2.2 \mathrm{ppb} \mathrm{K}^{-1}$ ). The VT-NMR analyses of CPPs $\mathbf{1 4}$ and $\mathbf{1 5}$ were consistent with parent peptide 3a, supported again the presence of strong hydrogen bonds on $\mathrm{Val}^{4} \mathrm{NH}$ and isoAsp ${ }^{5} \mathrm{NH}$. For peptide 16, the VT-NMR results indicated the similar hydrogen bonding network on $\mathrm{Asp}^{3} \mathrm{NH}$ as for the parent $\mathbf{3 c}$, albeit with a much weaker hydrogen bond ( $\left.\Delta \delta / \Delta \mathrm{T}=-2.6 \mathrm{ppb} \mathrm{K}^{-1}\right)$.

Table S2. $\Delta \delta / \Delta \mathrm{t}$ values ( $\mathrm{ppb} \mathrm{K}^{-1}$ ) of amide protons for LDV CPPs (CPPs) 3a-d, and of the correlated 11a, 11c, 12a, 12c, 13-16 by VT NMR spectroscopy, determined at $400 \mathrm{MHz}(\mathbf{3 a - d}, 11 \mathrm{a}, 11 \mathrm{c}, \mathbf{1 2 a}, \mathbf{1 2 c}, \mathbf{1 3})$ or at $600 \mathrm{MHz}(\mathbf{1 4 - 1 6})$ in DMSO- $d_{6} / \mathrm{H}_{2} \mathrm{O}$ (8:2) over the range 298-318 K.

Figure S14. PDB 3V4V, crystal structure of $\alpha_{4} \beta_{7}$ headpiece complexed with RO0505376; left, the integrin is represented as molecular solvent-excluded surfaces (SES) and colored using Coulombic electrostatic potential (ESP). RO0505376 is rendered in sticks, while metal ions were rendered as green spheres.

Figure S15. In-solution (top) and receptor-bound (bottom) structures of 3a, 3c showing hydrogen-bonded secondary structure elements (dotted lines). The structures differ only by the inversion of stereochemistry at Phu ${ }^{1}$. $\beta_{1}$ :Tyr ${ }^{133}$ and cations of the adhesion sites are shown for better comparison.

Figure S16. Left. Rendering of $\alpha_{4} \beta_{1}$ integrin model used in this work, with evidenced the $\beta$-propeller ( $\alpha_{4}$ ), Thigh ( $\alpha_{4}$ ), $\beta I\left(\beta_{1}\right)$, Hybrid ( $\beta_{1}$ ) and PSI (plexin-semaphorin-integrin, $\beta_{1}$ ) domains. The $\alpha_{4}$ subunit is colored in blue and represented as solid ribbon, with key residues at the $\alpha_{4} / \beta_{1}$ interface in stick. The $\beta_{1}$ subunit is represented as gray CPK , with key residues at the $\alpha_{4} / \beta_{1}$ interface in pink. (A) Close look of the interface between the $\beta$-propeller ( $\alpha_{4}$ ) and $\beta$ I ( $\beta_{1}$ ) domains. The $\alpha_{4}$ residues are shown in stick representation and colored in blue (black labels), while the $\beta_{1}$ residues are represented in CPK, with key residues colored in pink (white labels). (B) Particular of the interface between Thigh ( $\alpha_{4}$ )
and PSI $\left(\beta_{1}\right)$ domains. Again, the $\alpha_{4}$ residues are represented as blue sticks (black labels), while the $\beta_{1}$ residues are represented in CPK, with key residues colored in pink (white labels). Molecular graphics and analyses performed with UCSF ChimeraX.

Figure S17. The agonist 3a, c[(S)-Phu-LDV-(S)-isoAsp], makes many interactions with $\alpha_{4}$ subunit. Phu ${ }^{1} \mathrm{MePh}$ group interacts with $\alpha_{4}: \mathrm{F}^{214}\left(\pi-\pi\right.$ stacking), Phu ${ }^{1} \mathrm{Ph}$ interacts with $\alpha_{4}: \mathrm{F}^{214}\left(\pi-\pi\right.$ T-shaped interaction), and with $\alpha_{4}: \mathrm{Y}^{187}(\pi-\pi$ stacking). UreaC=O makes a hydrogen bond with $\alpha_{4}: \mathrm{K}^{213}(2.31 \AA)$. $\mathrm{Phu}{ }^{1} \mathrm{C}=\mathrm{O}$ establishes intramolecular hydrogen bonds with $\mathrm{Asp}^{3} \mathrm{NH}(1.72 \AA)$ and $\mathrm{Val}^{4} \mathrm{NH}(2.30 \AA)$. The hydrophobic side chain of $\mathrm{Leu}^{2}$ is included within a cavity delimited by $\alpha_{4}: \mathrm{K}^{157}, \beta_{1}: \mathrm{L}^{225}$, and $\alpha_{4}: \mathrm{Y}^{187}$, while $\mathrm{Leu}^{2} \mathrm{NH}$ group makes a hydrogen bond with $\beta_{1}: \mathrm{N}^{224} \mathrm{O}(1.84 \AA)$. Asp ${ }^{3} \mathrm{COO}^{-}$makes a salt bridge with $\alpha_{4}: \mathrm{K}^{157} \mathrm{~N} \zeta^{+}(1.63 \AA)$, while $\mathrm{Asp}^{3} \mathrm{C}=\mathrm{O}$ gives rise to an hydrogen bond with $\beta_{1}: \mathrm{Q}^{191} \mathrm{CONH}_{2}(1.78 \AA) . \mathrm{Val}^{4} \mathrm{C}=\mathrm{O}$ is hydrogen bonded to $\beta_{1}: \mathrm{S}^{134} \mathrm{OH}(1.97 \AA)$. The isopropyl of Val ${ }^{4}$ is pseudo axial, therefore it does get in touch with any residues of $\beta_{1}$ subunit. Finally, isoAsp ${ }^{5} \mathrm{COO}^{-}$is coordinated to $\mathrm{Mg}^{2+}$ in MIDAS, with $\mathrm{Mg}^{2+}$ that exhibits a slightly distorted coordination geometry (RMSD 0.12). Two hydrogen bonds are formed with water (W) W1 (2.86 $\AA$ ) and W3 ( $2.67 \AA$ ), an hydrogen bond with $\beta_{1}: Y^{133} \mathrm{NH}(1.97 \AA)$ and an hydrogen bond with $\beta_{1}: \mathrm{N}^{224} \mathrm{NH}(2.75 \AA)$.

The antagonist 3c, c[(R)-Phu-LDV-(S)-isoAsp], differs from the all-S configured 3a for the inverted stereochemistry at $\mathrm{Phu}^{1}$. The most noticeable effect is represented by a greater interaction with $\beta_{1}$ subunit. Phu ${ }^{1} \mathrm{MePh}$ makes a $\pi-\pi$ stacking interaction with $\beta_{1}: \mathrm{F}^{321}$. UreaNH makes a hydrogen bond with $\beta_{1}: \mathrm{S}^{227} \mathrm{OG}(2.11 \AA)$, and $\mathrm{Phu}{ }^{1} \mathrm{Ph}$ interacts with the peptide bond between $\beta_{1}: D^{226}$ and $\beta_{1}: S^{227}$ (amide- $\pi$ stacking). The side chain of $\mathrm{Leu}^{2}$ is included within the cavity formed by $\alpha_{4}: \mathrm{K}^{157}, \alpha_{4}: \mathrm{Y}^{187}, \beta_{1}: \mathrm{L}^{225}$. Leu ${ }^{2} \mathrm{C}=\mathrm{O}$ makes an hydrogen bond with $\beta_{1}: \mathrm{K}^{182} \mathrm{NH} \zeta^{+}(1.77 \AA)$, which in turn interacts with $\mathrm{Asp}^{3} \mathrm{COO}^{-}$by a salt bridge ( $1.62 \AA$ ). Val ${ }^{4} \mathrm{C}=\mathrm{O}$ makes two hydrogen bonds with $\beta_{1}: \mathrm{S}^{134} \mathrm{OH}(1.97 \AA)$ and $\beta_{1}: S^{134} \mathrm{NH}(1.52 \AA)$. In contrast to $\mathbf{3 a}$, the isopropyl of $\mathrm{Val}^{4}$ is in contact with $\beta_{1}: \operatorname{Tyr}^{133}(\pi-\mathrm{alkyl}, 4.76 \AA)$. Finally, isoAsp ${ }^{5} \mathrm{COO}^{-}$is coordinated with $\mathrm{Mg}^{2+}$. In this complex, the cation show a distorted octahedral coordination geometry (RMSD 0.17); isoAsp ${ }^{5} \mathrm{COO}^{-}$makes also other interacts: with $\beta_{1}: \mathrm{S}^{132}$ (O-HC, $2.46 \AA$ ), two hydrogen bonds with $\mathrm{W}^{1}$ (2.60 $\AA$ ) and $\mathrm{W}^{3}(2.66 \AA)$, hydrogen bond with $\beta_{1}: \mathrm{N}^{224} \mathrm{NH}(1.92 \AA)$.

## Molecular graphics and detailed analysis of the interactions between ligands and integrin $\alpha_{4} \beta_{1}$ receptor

 model. The following figures show the best binding conformation of the ligands within $\alpha_{4} \beta_{1}$ integrin binding site, represented as molecular solvent-excluded surfaces (partially transparent), colored using Coulombic electrostatic potential (ESP), with default coloring ranging from red for negative potential through white to blue for positive potential. Ligands are rendered in sticks, while metal ions belonging to MIDAS and ADMIDAS are rendered as green colored spheres. Key receptor residues in thick sticks. Molecular graphics and analyses were performed with Biovia Discovery Studio visualizer.

Figure S18. The CPPs 12a, $c\left[(S)\right.$-Phu-LAV- $(S)$-isoAsp], maintains the same stereochemistry as 3a, but Asp ${ }^{3}$ is replaced by $\mathrm{Ala}^{3}$. Phu ${ }^{1} \mathrm{MePh}$ group is in contact with $\beta_{1}: \mathrm{F}^{321}$ through a $\pi-\pi$ stacking interaction and $\alpha_{4}: \mathrm{K}^{213} \mathrm{NH} \zeta^{+}$through a $\pi$ cation interaction ( $2.12 \AA$ ). UreaC= $=O$ makes a conventional hydrogen bond with $\beta_{1}: S^{227} \mathrm{OH}(2.21 \AA)$. Phu ${ }^{1} \mathrm{Ph}$ interacts with $\alpha_{4}: \mathrm{F}^{214}$ through $\pi-\pi$ T-shaped interaction and with $\alpha_{4}: \mathrm{Y}^{187}$ through a stacked $\pi-\pi$ interaction. Phu ${ }^{1} \mathrm{C}=\mathrm{O}$ makes two intramolecular hydrogen bonds with $\mathrm{Ala}^{3} \mathrm{NH}(1.78 \AA)$ and $\mathrm{Val}^{4} \mathrm{NH}(2.91 \AA)$. Leu ${ }^{2} \mathrm{NH}$ give rise to a hydrogen bond with $\beta_{1}: \mathrm{N}^{224} \mathrm{O}(1.76 \AA)$, while Leu ${ }^{2} \mathrm{C}=\mathrm{O}$ makes a hydrogen with $\beta_{1}: \mathrm{K}^{182} \mathrm{NH} \zeta^{+}(2.01 \AA)$. In addition to the intramolecular bond with $\mathrm{Phu}{ }^{1} \mathrm{C}=\mathrm{O}, \mathrm{Ala}^{3}$ shows an additional hydrogen bond between $\mathrm{Ala}^{3} \mathrm{C}=\mathrm{O}$ and $\beta_{1}: \mathrm{N}^{191} \mathrm{H} \varepsilon(1.89 \AA)$. The methyl of Val $^{3}$ nicely packs against methyl of $\beta_{1}: T^{188}$. Val ${ }^{4} \mathrm{C}=\mathrm{O}$ makes two hydrogen bonds, with $\beta_{1}: \mathrm{S}^{134} \mathrm{NH}(2.95 \AA)$ and $\beta_{1}: S^{134} \mathrm{OH}(1.69 \AA)$. isoAsp ${ }^{5}$ residue coordinates $\mathrm{Mg}^{2+}$ (RMSD 0.11). Furthermore, isoAsp ${ }^{5} \mathrm{COO}^{-}$is involved in a hydrogen bonds network with $\mathrm{W}^{1}(2.83 \AA)$, $\mathrm{W}^{3}(2.72 \AA), \beta 1: \mathrm{Y}^{133} \mathrm{NH}(2.45 \AA), \beta_{1}: \mathrm{N}^{224} \mathrm{NH}(2.08 \AA)$ and $\beta_{1}: \mathrm{N}^{224} \mathrm{NH} \delta 21$ ( $2.55 \AA$ ).

Figure S19. Detail of the upper region of the binding site of $\alpha_{4} \beta_{1}$ integrin hosting 12a, $c[(S)$-Phu-LAV-( $(S)$-isoAsp]. Receptor residues in contact with the cyclopeptide are rendered as CPK models; residues of $\alpha_{1}$ subunit are highlighted in yellow. The sequence $\mathrm{A}^{181}-\mathrm{K}-\mathrm{L}-\mathrm{R}-\mathrm{N}-\mathrm{P}-\mathrm{C}-\mathrm{T}^{188}$ of the $\beta_{1}$ subunit is replaced by $\mathrm{S}^{191}$-K-L-R-H-P-C-P ${ }^{198}$ in $\beta_{7}$ subunit. In the $\alpha_{4} \beta_{1}-\mathbf{1 2 a}$ complex, the side chain of $\mathrm{Thr}^{188}$ of $\beta_{1}$ subunit invades the space of Val ${ }^{3}$, so that the methyl of the latter nicely packs against the methyl of Thr ${ }^{188}$. In the $\beta_{7}$ subunits, this residue is mutated for Pro ${ }^{198}$.

Figure S20. The CPPs 12c, $c[(R)$-Phu-LAV- $(S)$-isoAsp], is an analogue of $\mathbf{3 c}$, sharing the same stereochemistry array, in which Asp $^{3}$ is replaced by $\mathrm{Ala}^{3}$. This cyclopeptide shows interactions with both $\alpha_{4}$ and $\beta_{1}$ subunits. MePh group of $\mathrm{Phu}^{1}$ is in contact with $\alpha_{4}: \mathrm{K}^{213}$ ( $\pi$-cation interaction with $\mathrm{NH} \zeta^{+}, 3.76 \AA$, plus $\pi$-alkyl, $3.76 \AA$ ) and with $\beta_{1}: \mathrm{F}^{321}(\pi$-alkyl, $4.37 \AA)$. UreaC $=\mathrm{O}$ is hydrogen bonded to $\alpha_{4}: \mathrm{K}^{213} \mathrm{NH} \zeta^{+}(1.84 \AA)$, while both ureaNHs are hydrogen bonded to $\beta_{1}: \mathrm{Glu}^{320} \mathrm{COO}^{-}(1.94 \AA, 2.90 \AA)$. The side chain of $\mathrm{Leu}^{2}$ is inserted within the cavity delimited by $\beta_{1}: \mathrm{L}^{225}, \alpha_{4}: \mathrm{K}^{157}$, $\alpha_{4}: \mathrm{Y}^{187}$, making hydrophobic interactions. Ala ${ }^{3} \mathrm{NH}$ is involved in a intramolecular hydrogen bond with isoAspC=O $(2.03 \AA), \mathrm{Ala}^{3} \mathrm{C}=\mathrm{O}$ makes a hydrogen bond with $\beta_{1}: \mathrm{N}^{191} \mathrm{CONH}_{2}(2.19 \AA)$, while Ala ${ }^{3}$ methyl is close to $\beta_{1}: \mathrm{T}^{188}$ methyl (alkyl interaction). $\mathrm{Val}^{4} \mathrm{NH}$ is involved in a intramolecular hydrogen bond with isoAspC=O (1.81 $\AA$ ), $\mathrm{Val}^{4} \mathrm{C}=\mathrm{O}$ is hydrogen bonded to $\beta_{1}: S^{134} \mathrm{NH}\left(2.79 \AA\right.$ ), but Val ${ }^{4}$ isopropyl is directed perpendicularly above the molecular plane, therefore making very little contacts with any residues of $\beta_{1}$ subunit. Finally, isoAsp ${ }^{5} \mathrm{COO}^{-}$is coordinated to $\mathrm{Mg}^{2+}$ in MIDAS.

Figure S21. The CPP 15 was obtained from 3a by replacing Leu ${ }^{2}$ with $\mathrm{Phe}^{2}$ and $\mathrm{Asp}^{3}$ with $\mathrm{Ala}^{3}$. The Phu ${ }^{1} \mathrm{MePh}$ group is located between the residues $\beta_{1}: \mathrm{F}^{321}$ and $\alpha_{4}: \mathrm{K}^{213}$, with which it interacts giving rise to a $\pi-\pi$ stacking interaction and a $\pi$-cation interaction ( $3.19 \AA$ ). UreaC $=O$ makes a conventional hydrogen bond with $\beta_{1}: \mathrm{S}^{227} \mathrm{OH}(2.05 \AA)$, while Phu PH makes a $\pi-\pi$ stacking interactions with $\alpha_{4}: \mathrm{Y}^{187}$. Phu ${ }^{1} \mathrm{C}=\mathrm{O}$ makes two intramolecular hydrogen bonds with $\mathrm{Ala}^{3} \mathrm{NH}(1.72$ $\AA$ ) and $\mathrm{Val}^{4} \mathrm{NH}(2.15 \AA)$. Phe ${ }^{2} \mathrm{NH}$ makes two hydrogen bonds with $\beta_{1}: \mathrm{N}^{224} \mathrm{O}(2.87 \AA)$ and with $\beta_{1}: \mathrm{L}^{225} \mathrm{O}(2.14 \AA)$, while $\mathrm{Phe}^{2} \mathrm{Ph}$ is hold in position by a $\pi$-cation interaction with $\beta_{1}: \mathrm{K}^{182} \mathrm{~N} \zeta^{+}(4,01 \AA)$. In addition to the intramolecular hydrogen bonds with $\mathrm{Phu}^{1}$, Ala ${ }^{3}$ residue makes an hydrogen bond between $\mathrm{C}=\mathrm{O}$ and $\beta_{1}: \mathrm{Gln}^{191} \mathrm{H} \varepsilon 22$ ( $1.89 \AA$ ), while the Val $^{4} \mathrm{C}=\mathrm{O}$ forms an hydrogen bond with $\beta_{1}: \mathrm{S}^{134} \mathrm{OH}(1.85 \AA)$. The carboxyl group of the isoAsp ${ }^{5}$ residue makes two water-hydrogen bonds with $\mathrm{W}^{1}(2.84 \AA)$ and $\mathrm{W}^{3}(2.70 \AA)$, an hydrogen bond with $\beta 1: \mathrm{Y}^{133} \mathrm{NH}(2.12 \AA)$ and an hydrogen bond with $\beta_{1}: \mathrm{N}^{224} \mathrm{NH}(2.30 \AA)$. isoAsp $\mathrm{COO}^{-}$coordinates the magnesium ion in MIDAS (RMSD 0.15).

Figure S22. ${ }^{1} \mathrm{H}$ NMR (8:2 $\mathrm{DMSOd}_{6} / \mathrm{H}_{2} \mathrm{O}$ at 400 MHz ) and ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{DMSOd}_{6}, 100 \mathrm{MHz}\right)$ of 3a.

Figure S34. RP HPLC analyses performed on a column Phenomenex mod. Gemini $3 \mu \mathrm{~m} \mathrm{C}_{18} 110 \AA 100 \times 3.0 \mathrm{~mm}$; mobile phase from $9: 1 \mathrm{H}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN} / 0.1 \% \mathrm{HCOOH}$ to $2: 8 \mathrm{H}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN} / 0.1 \% \mathrm{HCOOH}$ in 20 min , flow rate of 1.0 mL $\mathrm{min}^{-1}$. DAD 254 nm , unless otherwise specified. For peptide 14, the analytical flow rate is $0.5 \mathrm{~mL} \mathrm{~min}^{-1}$.

Figure S34-follows. RP HPLC analyses performed on a column Phenomenex mod. Gemini $3 \mu \mathrm{~m} \mathrm{C}_{18} 110 \AA 100 \times 3.0$ mm ; mobile phase from 9:1 $\mathrm{H}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN} / 0.1 \% \mathrm{HCOOH}$ to $2: 8 \mathrm{H}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN} / 0.1 \% \mathrm{HCOOH}$ in 20 min , flow rate of 1.0 $\mathrm{mL} \mathrm{min}^{-1}$. DAD 254 nm , unless otherwise specified. For peptide 14, the analytical flow rate is 0.5 mL min .
