## 1 **Abstract**

2 Proteins are sources of peptides and amino acids which are able to stimulate  
3 plant growth through mechanisms such as enhancement of root growth and  
4 increased availability of micronutrients. Protein-based matrices are a novel  
5 source of these raw materials since they allow their availability in small, prolonged  
6 doses, which could be of interest in *in-vitro* assays. Thus, this work aimed to  
7 evaluate the use of soy protein-based matrices in *in-vitro* cultures of cv.  
8 *Magliocco Canino*, Their influence was assessed in different media conditions in  
9 the presence or absence of zinc (an essential microelement for plant growth).  
10 The shoots were evaluated based on their growth parameters (weight increase,  
11 number of stems, number of leaves, stem and internode length). A biochemical  
12 profile of the shoots cultivated in different media was obtained by FTIR. The  
13 results highlighted the benefits of using protein-based matrices in *in-vitro* culture  
14 as shoots showed an increase in weight, number of leaves, and longer stems,  
15 also in zinc-deficient media. In conclusion, this work emphasizes the potential of  
16 protein-based matrices as stimulants for grapevine explants.

17 **Keywords:** Grapevine; *In-vitro* culture; Matrices; Proteins, Stimulants.

## 18 **1. INTRODUCTION**

19 Amino acids are organic molecules composed of amino and carboxylic groups <sup>1</sup>.  
20 The main route of amino acid supply to the plant is through the root, which take  
21 up both amino acids, inorganic and organic nitrogen from the soil <sup>2,3</sup>. Plants  
22 transform inorganic nitrogen ( $\text{NO}_3^-$  and  $\text{NH}_4^+$ ) into amino acids for the consequent  
23 synthesis of proteins <sup>4</sup>. In this way, amino acids are present in every metabolic  
24 reaction and plant structure <sup>5</sup>. Highlighting the potential use of amino acid-based  
25 products for crop production, which have the complex power to protect some  
26 nutrients <sup>6,7</sup>. In addition, they increase the mobility of fairly mobile nutrients (i.e.,  
27 calcium, zinc, iron, etc.), thereby reducing and preventing plant stress <sup>8,9</sup>.

28 The synthesis of amino acids from inorganic nitrogen requires a high amount of  
29 energy <sup>2,10</sup> which is also critical in stressful situations (drought, disease, sudden  
30 temperature variations, etc.) when free amino acids are needed up to 100 more  
31 times <sup>11</sup>. This decreases the formation of proteins, therefore negatively impacting  
32 plant growth <sup>12,13</sup>. For this reason, the application of peptides and free amino  
33 acids may favor all plant processes in which proteins are involved. In this sense,  
34 many authors have used amino acids and peptides to promote plant growth. For  
35 example, Noroozlo et al. (2019) evaluated the stimulating effect of glycine and  
36 glutamine on lettuce growth <sup>14</sup>. On the other hand, Ghasemi et al. (2012) provided  
37 a solution to iron deficiency in tomato plants through the synthesis of iron-amino  
38 acid chelates <sup>15</sup>. It is worth mentioning that although the goal of these amino acids  
39 is the synthesis of proteins, these proteins cannot be exogenously incorporated  
40 into the plant due to their size and molecular weight <sup>16</sup>.

41 The use of protein as a source of amino acids has not been fully explored due to  
42 its complex structure that requires protease digestion to obtain those amino acids

43 17. However, this digestion is ensured due to the enzymes secreted by the  
44 microbes and the plants themselves<sup>18</sup>. Therefore, proteins could be used as  
45 amino acid source. In addition, it has the advantage of slow digestion, so it can  
46 provide amino acids for a longer time, being efficient throughout all the crop  
47 growth without needing more nutrients<sup>19</sup>.

48 Agri-food wastes can be a great alternative to providing these proteins due to  
49 their low price and high protein content<sup>20</sup>. Nevertheless, these residues have  
50 great amounts of water, so it is necessary to stabilize them in order to use them  
51 in plant production without detrimental effects<sup>21</sup>. In this sense, the formation of  
52 protein-based matrices, through the application of temperature and pressure, can  
53 be an easy and economical solution to obtain a product with a stable high protein  
54 concentration<sup>22,23</sup>.

55 *In-vitro* culture aims to grow plants in an aseptic-controlled environment, reducing  
56 the effect of factors that affect plant growth<sup>24</sup>. However, the use of media has  
57 difficulty reproducing natural conditions under laboratory conditions, as well as  
58 supplying plants with what was previously obtained from the complete system<sup>25</sup>.  
59 The use of the protein-based matrices asset in this work can represent a source  
60 of amino acids for *in vitro* cultivated plantlets.

61 Zinc is a microelement, required for different plant enzymatic activity, metabolic  
62 pathways, protein synthesis, and carbohydrate metabolism, and is also involved  
63 in the synthesis of tryptophan, cell division, maintenance of membrane structure  
64 and photosynthesis<sup>26,27</sup>. The most characteristic symptoms of zinc deficiency in  
65 fruit trees, rosetting and little leaf, are the results of strong inhibition of internode  
66 elongation and leaf expansion<sup>28</sup>. In addition, zinc can also be involved in plant-

67 pathogen interactions. In this sense, zinc is used by plants to combat pathogens,  
68 intoxicating them and controlling their proliferation <sup>29</sup>.

69 The main objective of this work was the evaluation of the use of soy protein-based  
70 matrices in *in-vitro* culture. We aimed to verify if the application of protein-based  
71 matrices could improve the performance of *in-vitro* cultivated plants. *Magliocco*  
72 *Canino 'Ninno'* shoots were selected. *Magliocco Canino "Ninno"* is a biotype  
73 present in the Calabria Region (Italy) which displays some peculiarities with  
74 respect to the standard *Magliocco Canino* genotype as leaves produces small  
75 berries without seeds. The productivity of this plant is very limited <sup>25</sup>; therefore *in-*  
76 *vitro* study can contribute to understanding the possible causes of its peculiarities.  
77 Thus, their influence on shoots was studied using different media with or without  
78 zinc deficiency. To this purpose, the parameters (weight increase, number of  
79 stems, number of leaves, stem, and internode length) of the shoots were  
80 monitored throughout the study. In addition, an estimation of the biochemical  
81 profile of these shoots was performed by FTIR.

## 82 **2. MATERIALS & METHODS**

### 83 **2.1 Materials**

84 In this study micropropagated *Magliocco Canino "Ninno"* shoots were used, in  
85 order to assess different substrates in a completely randomized experimental  
86 design. The culture employed as an explant source had been previously  
87 stabilized on the media tested in this experiment, further referred to as 'Standard  
88 modQL'. Under laminar flow, with a scalpel apical shoot portions ( $37.7 \pm 13.6$  mg)  
89 were aseptically detached, including the first four visible, sub-apical internodes  
90 ( $2.8 \pm 1.8$  mm long).

91 A salt formulation previously tested on Magliocco Canino Ninno [28] was selected  
92 for this study (Table 1): 'mQL', i.e. a modified Quoirin and Lepoivre <sup>30</sup>, with the  
93  $\text{NH}_4\text{NO}_3$  concentration further increased to 7.5 mM (Negri, unpublished). It was  
94 tested either as its standard or Zinc-deficient compositions. For all the tested  
95 media the same organic base was used at pH 5.7: sucrose ( $30 \text{ g L}^{-1}$ ), myoinositol  
96 ( $100 \text{ mg L}^{-1}$ ), thiamine ( $1 \text{ mg L}^{-1}$ ), nicotinic ( $1 \text{ mg L}^{-1}$ ), pyridoxine ( $1 \text{ mg L}^{-1}$ ),  
97 glycine ( $2 \text{ mg L}^{-1}$ ), BA ( $1 \text{ mg L}^{-1}$ ), IBA ( $0.05 \text{ mg L}^{-1}$ ) and agar ( $7.5 \text{ g L}^{-1}$ ). All the  
98 reagents used in the media were analytical grade.

99 Soy protein-based matrices were used to supply proteins to the medium. They  
100 were processed with a similar protocol to those described by Jiménez-Rosado et  
101 al. <sup>22</sup>. Briefly, soy and glycerol (ratio 1:1) were homogenized in a rotating mixer  
102 (Polylab QC, ThermoHaake, Germany) at 50 rpm for 10 min, and they were  
103 subsequently injected in a MiniJet Piston Injection Molding System II  
104 (ThermoHaake, Germany); parameters used:  $40 \text{ }^\circ\text{C}$  and  $90 \text{ }^\circ\text{C}$  in the cylinder and  
105 mold, 600 bar of injection pressure for 20 s, and 300 bar of holding pressure for  
106 300 s to obtain the bioplastic matrices. This system was immersed in 300 mL of  
107 ethanol for 24 h to remove the glycerol. The protein-based matrices were  
108 obtained after a freeze-drying process (LyoQuest, Telstar, Spain), with a  
109 biodegradability of 40 days, providing nitrogen, which can also be taken up by  
110 plants. The amino acid composition of the soy protein used is shown in Table 2.  
111 It should be noted that the matrices that are the object of study in this work do  
112 not contain any other component apart from the protein.

## 113 **2.2 *In-vitro* culture treatments**

114 Four different treatments were imposed: (i) standard medium (control), (ii) zinc-  
115 deficient medium (i.e., the same as the standard medium, but lacking

116 ZnSO<sub>4</sub>·7H<sub>2</sub>O), (iii) standard medium with protein-based matrix and (iv) zinc-  
117 deficient medium with the protein-based matrix. Once autoclaved (20 min at 121  
118 °C, 1 bar) into Pyrex bottles, the substrates were transferred to the laminar flow  
119 and aliquoted (10 ml) into previously sterilized, 55 ml glass tubes (30 mm  
120 diameter). After medium gelation a shoot was positioned in the center of each  
121 tube. A matrix fragment (70 mg approximately) was introduced beside the  
122 sample. Finally, each tube was non-hermetically sealed with an aluminum cap  
123 and fastened with a single layer of polyethylene film. The process was carried out  
124 under sterile conditions in a laminar flow hood.

125 Shoots were kept for 35 days in a culture chamber with 16 hours of light (intensity  
126 of 35 µcd) at a temperature of 26 ± 2 °C.

### 127 **2.3 Assessment of morphological and physiochemical plant traits**

128 The different samples were hermetically preserved during their cultivation to  
129 avoid contamination of the environment. After 35 days, the plants were first  
130 dissected with a scalpel to facilitate their analysis. Later, their weight increase  
131 (final fresh weight – initial fresh weight), the number of stems and leaves, as well  
132 as the length of their stems and internodes were determined. In addition, the  
133 morphology of the leaves was observed.

134 Tissue zinc concentration was also determined in the different samples. For this,  
135 inductively coupled plasma-atomic emission spectroscopy (ICP-AES) was  
136 carried out. The plants were subjected to a previous digestion with 7:1 ratio of  
137 HNO<sub>3</sub>:H<sub>2</sub>O<sub>2</sub> to obtain an aqueous solution which contain the zinc present in the  
138 samples. Then, the aqueous solutions were analyzed in an ICP SpectroBlue TI  
139 (Spectro, Germany) to obtain the zinc concentration.

140 Finally, the leaves of the different treated shoots were also analyzed by Fourier  
141 transform infrared spectroscopy (FITR) to evaluate the biochemical profile of  
142 each shoot <sup>31</sup>. A MIR-ATR-XPM spectroscope (Bruker, USA) was used to obtain  
143 the absorbance profile of each sample between 4000 and 400 cm<sup>-1</sup>, with a  
144 resolution of 4 cm<sup>-1</sup>. To obtain the profile, an average of 100 scans was  
145 performed.

## 146 **2.6 Statistical analysis**

147 At least six replicates were performed for each analysis and system. All the data  
148 were reported as average values. An analysis of variance was performed.  
149 Tukey's post hoc test with a confidence level of 95% ( $p < 0.05$ ) was performed  
150 using the SPSS 18 statistical package (Excel, Microsoft, USA) to evaluate the  
151 significant differences, which were reported with different letters.

152

## 153 **3. RESULTS & DISCUSSION**

154 Table 3 shows the parameters obtained for the shoots submitted to the different  
155 treatments i, ii, iii, and iv. The inclusion of soy protein-based matrices increased  
156 weight and proliferation (higher number of stems and leaves). This behavior may  
157 suggest that the matrices improve plant formation due to the stimulation  
158 generated by the amino acids present in the matrix <sup>23,32,33</sup>. Soy protein presents  
159 high concentrations of glutamic acid (21.7%), which promotes plant development  
160 <sup>34</sup>; alanine (10.4%), which increases metabolic activity <sup>35</sup>; leucine (8.6%) and  
161 aspartic acid (8.2%), which are important in the growth, development, and  
162 flowering of plants <sup>36</sup>. The proteins break down into amino acids during

163 biodegradation<sup>37</sup>. These amino acids are an extra source of nitrogen and building  
164 blocks for enzymes, allowing plants to have more energy to develop<sup>38</sup>.

165 Zinc deficiency produces a slight decrease in weight (43% approximately)  
166 obtained from the plants (Table 3, i (media without matrix) vs. ii (zinc deficiency  
167 media without matrix)). In addition, zinc deficiency results into a lower tissue Zn  
168 concentration and increases the percentage of deformed leaves. These results  
169 could contribute to explain the smaller fruits produced by zinc-deficient plants<sup>39</sup>.  
170 The inclusion of the matrix compensates in part the lower weight increases due  
171 to zinc deficiency (Table 3, ii (zinc deficiency media without matrix) vs. iv (zinc  
172 deficiency media with matrix)). This effect may be due to the presence of amino  
173 acids provided by the protein matrix that allows the stimulation of the plant for the  
174 formation of the proteins and enzymes necessary for its growth. Nevertheless,  
175 the absence of zinc prevents the generation of enzymes necessary for plant  
176 growth, such as those needed for the synthesis of tryptophan<sup>40</sup>, making it unable  
177 to reach the levels obtained by the control plants.

178 Regarding tissue zinc concentration (Table 3), zinc-deficient media cause shoots  
179 to present a deficiency of this micronutrient (concentration < 11.5 ppm<sup>41</sup>). This  
180 deficiency may be the reason for the aforementioned defects in the shoots  
181 cultivated in this medium. The inclusion of the protein-based matrix has promoted  
182 the absorption of zinc (from the medium) by the shoots. In this way, the shoots  
183 obtained in the media with protein-based matrices (iii and iv) have a higher  
184 amount of zinc than those obtained without matrices (i and ii, respectively). In  
185 addition, it should be noted that the shoots obtained in the medium with zinc  
186 deficiency but with matrix (treatment iv) have a zinc concentration similar to the  
187 reference system (treatment i), although the matrix does not provide zinc.

188 Regarding the visual aspect of dissected plants (Fig. 1), zinc deficiency  
189 (treatment ii) caused higher leaf deformation (Table 3), an effect that has already  
190 been reported as a cause of micronutrient deficiency <sup>42,43</sup>. The inclusion of  
191 protein-based matrices decreased this effect, possibly due to the stimulant effect  
192 of amino acids and the higher energy available per plant <sup>44</sup>. Once again, the  
193 medium without zinc deficiency and with the incorporated matrix (treatment iii)  
194 was the one that generated the highest number of leaves, appearing the largest  
195 and least deformed (Table 3). This response suggests that the protein-based  
196 matrices incorporate amino acids into the plants, stimulating plant growth by  
197 increasing plant weight and number of leaves and less likely to be deformed, as  
198 seen in Table 3.

199 Finally, the biochemical profile of the leaves of differently treated plants is shown  
200 in Figure 2. The vibration band of the O-H group ( $3320\text{ cm}^{-1}$ ) is observed, which  
201 is due to the residual water present in the plants. The polysaccharides (cellulose,  
202 hemicellulose and lignin) present a band between  $1260$  and  $870\text{ cm}^{-1}$  due to the  
203 vibration mode of C-O-C groups. Other intense bands were found between  $2970$   
204 and  $2840\text{ cm}^{-1}$ , corresponding to the C-Hx vibrations of lipid content in the plants.  
205 In addition, the spectra show protein structures in the samples, which can be  
206 observed in the bands between  $1520$  and  $1280\text{ cm}^{-1}$ , corresponding to amide  
207 groups. All these peaks have also been identified in previous works, being the  
208 typical profile of other grapevine plants <sup>45-47</sup>. All treatments presented the same  
209 profile, so the biochemical composition of plants was not affected by the  
210 treatment used. This may be because, although plant growth is different in each  
211 medium and treatment, all systems form the same structures and bonds.

212 Using protein-based matrices may be beneficial for horticultural production,  
213 particularly in addressing zinc micronutrient deficiency in plants. The use of  
214 protein-based matrices incorporates beneficial stimulants such as amino acids,  
215 improving nutrient use efficiency, therefore minimizing losses while reducing the  
216 need for fertilizer applications and consequently environmental contamination.

217

#### 218 **4. CONCLUSIONS**

219 Protein-based matrices, especially those based on soy protein, have shown their  
220 high potential in the performance of *in-vitro* cultivated plants (treatments iii and  
221 iv). The *Magliocco Canino 'Ninno'* shoots selected for this essay presented a  
222 greater weight and number of leaves, reducing the appearance of defects and  
223 deformations when soy protein-based matrices were used (even in zinc-deficient  
224 media). All this was caused by the stimulant effect of proteins presented in these  
225 matrices. Thus, zinc deficiency symptoms were partially mitigated using protein  
226 matrices.

227 Controlled fertilization with protein-based matrices is a promising approach to  
228 providing nitrogen and addressing zinc micronutrient deficiencies in horticulture  
229 without the negative effects of conventional fertilization.

230 Nevertheless, this is a preliminary study on the use of these protein-based  
231 matrices. Future work is needed to assess the effects and mode of action of  
232 protein matrices on crops.

233

#### 234 **ACKNOWLEDGEMENTS**

235 This work is part of a research project (PID2021-124294OB-C21) funded by  
236 MCIN/AEI/10.13039/501100011033 and by “ERDF A way of making Europe”.  
237 The authors gratefully acknowledge their financial support. In addition, the  
238 authors thank for the predoctoral grant of Mercedes Jiménez-Rosado  
239 (FPU2017/01718, MEFP) and her research stay supported by MEFP. Finally, the  
240 authors acknowledge the assistance in microanalysis services of CITIUS  
241 (University of Seville).
